The central cylinder, or printing roller, is made of cast iron; the larger the number of colours printed, the greater the diameter of the cylinder. It is wrapped with several layers of springy cloth (lapping) to impart resilience. The back gray and the cloth to be printed are carried through the rollers at a steady tension on an endless printer's blanket, which may be made of felt with a smooth resilient surface or made of cloth coated with rubber or a plastic substance. If it is rubberized it will be washed after the impression with water sprays or rotary cylindrical brushes to remove adhering paste, and dried by being passed through hot air or over steam-heated cylinders or by being dusted with talc before being passed forward again to support more cloth. Modern blankets, which are covered with compositions designed to resist wear and chemical attack and are embossed with fine lines, can be used without the back gray for some designs; the depressions hold the small amounts of paste pushed through the cloth and in addition increase the grip between cloth and blanket; such blankets exhibit better springiness than do the older forms.

The cleaning doctor consists of a straight strip of steel fixed in a pivoted clamp or shears, with an edge pressing at an angle against the surface of the shell. It removes the paste from the unengraved portions of the shell surface. The pressure of contact is obtained by weights that act on the shears through a lever. The adjustment of the doctor is one of the most exacting tasks of the printer since the variety of blade and the angle and pressure of contact have to be adjusted to meet the particular quality of the engraving and other conditions of printing. The edge is sharpened so that it is accurately linear, and, although it may receive an initial mechanical grinding, it always has to be finished by hand. Special adjustments (springing) of the steel strip in the shears are required to overcome bowing when wide cloths are printed.

As the shell rotates it is supplied with printing paste by a lapped or coated roller (the furnisher) that rotates in contact with the shell and also runs partly immersed in paste contained in a colour box. As the shell moves round it is cleaned by the doctor and then makes contact with the cloth. Before it completes a revo-

lution, it passes under the edge of a second, or lint, doctor that is similar to the cleaning doctor but is made of a softer metal. Here the smooth portion of the copper is freed from lint and from printing paste of other colours transferred by the cloth from an earlier shell. This operation prevents paste of one colour from passing into the boxes of subsequent colours and falsifying the shade and removes solid impurities that might otherwise wedge between the edge of the cleaning doctor and the copper surface, letting through unwanted colour and giving rise to lines and smears in the print. Furnishing is sometimes effected with a stiff cylindrical brush instead of a roller. The brush is often rotated at a different surface speed from that of the shell; the brushing action prevents permanent clogging of the engraving.

In multicolour printing, the units, each consisting of a shell printing a single colour with its own doctors and furnishing arrangement, are fixed at intervals round the lower part of the periphery of the central cylinder, which is horizontally disposed. As the cloth passes around the cylinder, it is impressed in succession with the different colour components. Careful fitting is needed as each impression must fall accurately upon the appropriate area within the complete pattern; inconspicuous pitch marks are engraved as a guide at the appropriate place on each shell of the set. Adjustments are made after the first few feet of cloth have been inched through the machine: to correct the fit across the width of the cloth the bearings of the mandrel are displaced sideways; adjustments at the box wheel can turn the mandrel slightly relative to the wheel itself and make the impression from one shell fall a little earlier or a little later within the repeat, ensuring longitudinal fit. Some adjustment of this kind may also be needed while the pattern is being printed, since the cloth may stretch a little unevenly under tension. The diameters of all the shells are the same and all are driven at the same rotational speed, so that the surface printing speed of each shell is therefore also the same. An integral number of repeats of the pattern is engraved around the circumference of each shell so that these repeats are printed without change of spacing regardless of the length of the cloth. With the older box-wheel mechanisms, adjustments in the fit were made manually and the slowing up necessary to effect them sometimes led to changes in the stretch of the cloth. However, more elaborate mechanical and electrical types of box wheels have become available; these allow the shift for fitting to be accomplished while printing at full speed.

Not all the rollers on a machine may be engaged in impression. Sometimes perfectly smooth, unpatterned rollers furnished with a paste containing no dye may be interposed in the sequence of engraved rollers when impressions of greater colour area, or with more intense colours, are printed on the cloth in front of impressions of smaller area or paler colours. This counteracts the danger of contaminating the pastes in the colour boxes toward the end of a series when the action of the lint doctor may not be adequate. The march roller receives any loose colour from the cloth on its smooth surface, goes around to be coated with plain paste and then has its surface scraped clean by the doctor. When a multicolour machine is used to print a design with fewer colours than its maximum capacity, the engraved rollers may be too few to pull the cloth, blanket and heavy cylinder by frictional contact in the usual way and in this case additional plain rollers are run on the machine for driving purposes.

Three important modifications of the roller printing machine are made to meet special requirements of pattern or quality of impression:

1. Surface printing machines have already been mentioned; they are used to give prints of blocklike quality. Since the printing is

from rollers in relief, modifications of the furnishing arrangements are needed.

2. Duplex printing machines are in effect two separate single-sided machines incorporated in the same structure and printing simultaneously on both sides of the cloth with the pattern on the one side in perfect fit with that on the other. Less perfect double-sided effects can be produced with single-sided printing in a push-through operation where the structure of the cloth, the pressure of the roller and the consistency of the paste allow the colour to go right through the cloth and give a reasonable impression on the underside.

3. Jumping machines are used for large repeats that are surrounded by an unprinted border. The machine is provided with gearing that checks the printing operation at the necessary intervals while the cloth moves forward by a distance equal to twice the width of the crosswise border. This obviates shells of inconveniently large diameter.

**Transfer of the Repeat to the Shell.**—*Milling.*—Patterns with small simple motifs and uncomplicated repeats such as spots, stars, rings, stripes, etc., are engraved by mounting the polished shell in a lathe and rotating it against a hard-steel, wheel-shaped die with a number of the design units in relief; these units indent the copper surface.

*Hand Engraving.*—To a limited extent, rollers are hand engraved by conventional methods. More frequently, hand engraving is employed to perfect rollers engraved by other methods and to correct defects caused by wear. (See also ENGRAVING, LINE.)

*Etching.*—This is the method used most frequently for engraving rollers. The original cartoon from the designer is projected optically onto a zinc plate and the repeat is incised on the plate, each detail being then coloured up to match the cartoon. An operator then follows the lines corresponding to one of the component colours on this plate with a stylus that forms part of a machine called a pantograph (or, less correctly, a pentagraph). Mounted in the pantograph is a smooth copper shell, covered with a layer of protective varnish; the movements of the stylus rotate the roller and also actuate a series of diamond points spaced along the length of the roller. As a result, the desired number of repeats are scratched at intervals along and around the shell. The roller is then rotated in a bath of suitable acids that penetrate the scratches and etch the repeats into the copper. If the engraving is a deep one it is not desirable to etch it in one stage, so the roller is revarnished and the scratching and acid treatment are repeated. When one roller of the set has been made, another is inserted in the pantograph, the lines on the zinc corresponding to a different colour are followed, and so on until the whole set has been completed.

*Photogravure Methods.*—A number of acid etching methods have been developed that follow the methods used to produce photogravure rollers for magazine printing. They reduce the time required for engraving and are specially suited for certain pictorial subjects.

*Scale.*—For all shapes of appreciable area, simple engraving of a depression in the roller will not give satisfactory impressions since the paste that it contains after furnishing is not under adequate control and the printed area consequently will not be uniformly coloured. Such areas are therefore engraved as a series of parallel diagonal grooves. In printing, each line spreads laterally into the impression of its neighbour. The width and depth of the lines must be properly related to each other; these measurements are jointly specified in a number called the scale. In some engravings made by photogravure methods the impression is broken into dots by photographing the original image through a screen (rectangular disposition of lines), and the effect of the screen is the same as that used in photomechanical methods for printing pictures on paper.

**Colourings.**—A set of engraved rollers, blocks or screens can be used to produce a series of different and distinct decorative effects by (1) changing the combination of colours; (2) using only part of the set; (3) using the set in conjunction with rollers having small "all over" patterns that do not need fitting with the rest of the pattern and modify the ground or the blotches; (4) print-

FIG. 3.—WORKING PARTS OF A ONE-COLOUR TEXTILE PRINTING MACHINE

ing in conjunction with dyeing. Each modification of the use of the set of rollers in this fashion is called a "way."

There are also several more unusual methods for continuous printing. In one group of related methods the colours are thickened until the printing medium is of the consistency of stiff dough. This is rolled out into sheets and cut into shapes that are mounted in mosaic fashion around the surface of a roller. This roller prints onto cloth dampened with water or other solvent; the cloth is supported on another roller with a very resilient surface. The water or other solvent dissolves a small amount of the thickened colour, which is thus transferred to the cloth. Only a limited yardage can be printed with one roller because the roller coating is slowly consumed. The process has been used to produce beautiful and unusual prints that cannot be obtained in any other way; there is no limit to the number of colours that can be printed from the one roller. The usual difficulties of fitting are not present, since these have been dealt with in preparation of the roller itself, but there are restrictions in the kinds of dye that can be used.

In another unusual continuous method the design is first printed on paper with appropriate dyes in special media. It is transferred to the fabric by running the cloth and the paper through a heated calender together. Once the transfer has been obtained, the dyes used are fixed in the normal way.

**Colouristic Features.**—The choice of dyes and their adaptation for use in a given print depend upon a large variety of conditions, some chemical and some economic: the fibre or fibres from

FIG. 4.—MODERN ROLLER GARMENT-PRINTING MACHINE

FIG. 4.—MODERN ROLLER GARMENT-PRINTING MACHINE

which the cloth is made, the colour requirements of the design to be reproduced and its durability in the expected conditions of use, the relation between the printed effect and later processes of manufacture (e.g., finishing), the cost of production and the length of time before delivery. Most commercial printing is a compromise between the ideal interpretation of the design and the need to produce it at an acceptable price. The choice of dyes for a print, and to some extent the chemical and processing procedures used in their application and fixation, are known as styles.

The relations between the kind of fibre in the material to be printed and the dyes used are in general similar to those that are obtained in dyeing but the physical differences in printing and dyeing systems may greatly modify the conditions of application. Two important differences are: (1) dye and chemical assistants used in printing have to be applied in a smaller volume of medium (i.e., concentrated); (2) the stage of diffusion and fixation in printing must be made to occur after the impression and in the relatively short, well-defined period of steaming or chemical aftertreatment. For this reason formulations of a dye bath and of a printing paste containing the same dye may be very different.

The following groups of dyes are used in printing:

- I. Direct cotton dyes, mainly for cellulose fibres; acid dyes for viscose, wool, silk, and nylon and certain other synthetics; basic dyes for wool, silk, cellulose esters; and disperse dyes for all hydrophobic fibres (those that swell very little in water).
- II. Vat dyes, predominantly for cellulose fibres but also, via special procedures) for other natural and synthetic fibres, insoluble azo dyes, mostly for cellulose fibres, and often in special chemical forms to meet the special conditions of printing; phthalocyanine dyes, again for cellulose fibres but again applicable in some chemical forms to other fibres.
- III. Mordant dyes, in which the sequence of application of the dye, the mordant and the reagents that control the interaction of the two are specially chosen for printing conditions.
- IV. Reactive dyes, which are mostly applicable to cellulose fibres.
- V. Pigment colours applied to the surface of the fibres and fixed with synthetic resin preparations so designed that, when fixed they are not easily removed in washing and do not stiffen the fabric. They are applicable to a wide range of fibres, are simple to use, give full colorations and are particularly useful in screen printing.

A distinctive feature of much textile printing as compared with dyeing is that it is often necessary to use dyes from different classes to provide the different coloured areas in the same print and for this reason, great ingenuity is needed in exploiting the chemical properties of individual dyes so that one fixation treatment, e.g., steaming, is appropriate for all of them and so that the reagents used with one colour do not interfere with the other colours.

Two widely used styles that have no exact counterpart in dyeing are: (1) Discharge printing, in which the cloth is first evenly dyed before printing and then is printed with a paste that contains either an oxidizing or a reducing agent. Steaming causes the agent to destroy the dye on which it falls or to convert it to a soluble form so that it can be removed by washing. This therefore gives a white print on a coloured ground. An extension of this method is the use of the illuminated discharge in which a dye different to the discharging agent is incorporated in the paste and it takes the place of the ground dye that has been destroyed. This gives a coloured print on a ground of a different colour. (2) Reserve or reserve styles, in which the cloth is printed with a preparation (e.g., wax or a synthetic resin) that protects the fibre from the dye solution, or with a reagent that chemically inhibits the fixation of a particular dye (e.g., an acid for a dye that requires alkali for its fixation). The entire cloth is then dyed and the resisted areas remain undyed. As with discharge styles the cloth may be plain (white on a coloured ground) or coloured. An additional example is the batik of Java and its analogue in African styles.

**TEXTILES** are woven fabrics. The term also means suitable fibres or materials suitable for weaving, in addition to the fabrics produced by knitting and felting, and all fibres. The word *textilis* meant a woven fabric, but the word *textile* was used as a transitive verb for plaited, braided, woven or knitted. This article deals largely with decorative textiles. Words related to the subject include SPINNING, and WEAVING for the making of textiles; DYES AND DYEING for one process of their finishing; TEXTILE PRINTING for a detailed description of

...ential aspects of that subject. There are also numerous individual fabrics—e.g., CALICO, CHALLIS, CHIFFON, DIMITY, etc.—which describe these fabrics and deal with systems of commerce. COTTON MANUFACTURE, SILK, etc., similarly are concerned with textiles as industrial products.

This article is outlined as follows:

### III. Indian Textiles

## I. HISTORICAL OUTLINE

**1. Early History.**—Since textiles are easily torn, burned or eaten by insects, the oldest surviving specimens probably date from long after the time when weaving was first practised. Whorls or weights for spinning have been found on Neolithic sites, indicating that thread was spun and therefore that cloth was made. The weaving of textiles for clothing, as a substitute for the skins of wild animals, was a corollary of settled life and the breeding of domestic animals. The four natural fibres, wool, linen, cotton and silk, originated in different parts of the world. Woolen textiles have been found in early Bronze Age sites in Switzerland and Scandinavia. In Egypt plain linen textiles of about 5000 B.C. have been found. Cotton scraps have been discovered in India on sites of about 3000 B.C. and in Peru on sites datable to 2000 B.C. Silk may have been used in China in the 2nd millennium B.C. and was certainly woven by 1000 B.C. Cloaks, tunics and caps from Scandinavian sites show that a high level of skill had already been reached there, even though tools were few and primitive. The elementary processes of carding and combing raw wool were known, for the threads are well and evenly spun. Felt caps and narrow braids were also made, and sprang, a technique between knitting and netting, was used.

Flax was grown in the Nile valley. The natural colour of flax is brownish, and since whitish linens have been found in early times, methods of bleaching must have been discovered. Spinning was done by hand, using a simple weighted spindle. Textiles were woven on three types of loom—a horizontal loom on the ground, an upright loom with a beam at the top and an upright loom with the warp threads bunched in and weighted at the foot. Variants of this last loom are shown on ancient Greek vase paintings, and this type was probably used to weave the textiles found in Scandinavia. Tablet weaving produced narrow braids, netting, sprang and other techniques developed. Normally cloth was woven in tabby (plain weave). In Ptolemaic Egypt very fine counts of linen have been found. Textiles probably woven for the courts of the Pharaohs, analogous to the garments found in the north are tunics of simple shape.

The Romans wore both linen and wool, but as the empire expanded so did the variety of textiles they imported. Pliny described the Roman toga of wool or linen, and later writers described fashionable clothes made of silk from China. From two Mesopotamian, Doura-Europus (deserted A.D. 256) and Tadmor (sacked A.D. 272), there are textiles showing the weaving of the ancient world to have comprised chiefly plain tabby—though at Palmyra some linens were dyed in true red and among the wrappings of the dead were some imported. Several of the earliest patterned materials made outside the Near East are also found. These are the tunics and fragments woven in linen with tapestry-woven insertions.

The designs of the fragments from Doura-Europus are comparatively simple; on the other hand for several centuries after the 3rd century A.D. Coptic weavers of Egypt produced an extraordinary variety of decorative textiles, chiefly for clothing. The dry sands of the burying grounds of Akhmim and Antinoë have preserved a profusion of such textiles dating from the 4th to the 10th centuries. The patterns reflect the customs and life of the ancient Mediterranean. The bands of decoration, which were narrow on the fronts and shoulders of the tunic fragments at Doura, were larger and more elaborate, with roundels containing mythological and biblical scenes. Naturalistic birds, animals, gods and mortals in fresh, bright colours influenced by Hellenistic art were gradually transformed in subject and in style. Long after the conquest by Islam in the 7th century the Coptic weavers continued to look back to Christian subjects for their inspiration. The influence of other countries and other media can be detected, and the patterns of woven silks were copied in wool. In time, however, whatever their origin, the motifs forming the designs were subordinated to a general decorative effect until they became almost unrecognizable.

Many animal-fibre (vicuña, llama, etc.), agave and cotton textiles have been found in the sands in the narrow coastal strip of South America between the Andes and the Pacific, relics of the pre-Columbian civilization of Peru. The earliest of such relics date from about A.D. 1000, though their chronology is uncertain. Without any further modification of the loom than the weaver's fingers could provide, the inhabitants wove complex patterned textiles in tapestry, double cloth, brocaded gauze and other techniques for belts, blankets, bags and clothing. Anthropomorphic subjects are common.

**2. Advances in Weaving.**—One of the most important developments in the history of textiles was the invention of a method of making free designs that could be repeated indefinitely once the loom was set up. It is certain that the Chinese had found a means of achieving this early in the Han dynasty (202 B.C.–A.D. 221). The Chinese loom probably had treadles and rotary cloth and warp beams before those in the west, both of which presuppose the weaving of large quantities of fairly complex materials. The invention of a drawloom implies a civilization so advanced that expensive textiles were produced for a wide commercial market—it would not be worthwhile otherwise to set up the pattern. Chinese silks have been found not only on the old silk road from China, at Loulan, Turkestan, and other sites by Sir Aurel Stein but also a group of silk damasks were among the textiles excavated at Palmyra.

On the drawloom it is possible to lift the warp threads required for the pattern irregularly across the textile in each line of the design. In China a drawboy sitting on top of the loom pulled a set of cords attached to all the warp threads necessary for that line of the pattern each time the weaver opened a new shed. The warp threads thus pushed to the back of the textile the weft not required on the surface. The setting up of such a loom was laborious and the work very slow and tiring for the boy or girl helping the weaver. Though several important modifications very much later made the drawloom a more efficient machine—by the 17th century, for instance, the introduction of lashes and spindles permitted the boy to work at the side of the loom—fundamentally the drawloom remained unchanged until the late 18th century. In the early Chinese silks the pattern was made either by a form of damask in which a warp-faced weave contrasted with a weft face, or by different coloured warp threads entered in sequence in the loom and brought to the surface as required by the design. The patterns of the early Han textiles were often similar to the geometric cartouches on the backs of bronze mirrors or were derived from a repertoire of exotic fauna, dragons and birds being especially common.

Farther west the first drawloom patterns appear in woolen textiles found in the Egyptian burying grounds and perhaps dating from the 4th–5th century A.D. A group of these show small bands within compartments, woven in compound tabby. The word compound indicates a two-warp system: the main warp controlled by the drawboy is hidden between the front and the back of the textile

and the binding warp appears on the surface to bind the wefts in tabby. These textiles were probably woven in the near east but it is not known where.

**3. 4th–15th Centuries.—Middle East.**—After the fall of the Roman empire textiles continued to be woven in the traditional centres and exported abroad. Following the Muslim conquests of the 7th century new textile centres appeared in Syria and Arabia. At the western end of the silk route across central Asia from China, silks were woven in Sogdiana and in Sasanian Persia (3rd–7th centuries A.D.). Important patrons of silk weaving were the Seljuks who ruled Persia, Asia Minor and Syria in the 11th and 12th centuries. Apart from a group excavated at Ray, few Persian textiles can be certainly attributed to an earlier date than this. A number of important silks can be attributed to Egypt in the time of the Mamelukes.

Most of these near-eastern textiles are known only from literary sources but from the 7th–8th century onward woven silks have survived in some quantity in the tombs and reliquaries of saints and other important figures, opened at later dates, and from the 12th century onward as the seal bags of treasuries and as vestments. Such silks often came from far-distant countries; thus silks from central Asia have been found in French and Flemish churches, and Chinese silks have even been found in Viking burial grounds. The designs of near-eastern silks owe little to China but much to the traditions of Sasanian art. In roundels fabulous monsters such as the *senmurv*, half-bird half-dog, are typical. The sculptures of the Sasanian monuments, especially at Taq-e Bostan, prove that such patterns, themselves based on Achaemenid art, originated in Persia. The roundel became the set form of decoration for several centuries, though the motifs it contained and the ornament from which it was composed varied considerably.

A magnificent series of woven silks can be attributed to Byzantium. Silk weaving may not have been very important in the city until the 6th century but very soon afterward imperial workshops were established which controlled the industry. The capture of Ctesiphon, the Sasanian capital of Khosrau II, in 624 and the booty taken by the Byzantine troops may have influenced the development of silks made in Byzantium. Early Byzantine silks were made in compound twill—that is, with the hidden main warp making the pattern and the binding in twill, allowing longer floats of weft than in tabby and thus exploiting the lustrous quality of the silk. Subjects owing much to the inherited tradition of Rome included the Quadriga silk showing a charioteer, and the lion strangler, perhaps Samson. Byzantine silks have been preserved in the tomb of Charlemagne at Aachen. This was opened in 1000 A.D. and new silks added—the elephant silk found there was probably made not long before the opening and is similar in style to lion silks elsewhere with 10th-century inscriptions. These were made in the golden age of Byzantine silk production. A group of silks were woven in the 11th century in which the pattern appeared as a penciled or engraved outline in a self-coloured material; the vestments of Pope Clement II (1046–47) at Bamberg, Ger., are remarkable examples.

While the richest silks fit for kings and emperors have survived, the ordinary wool and linen materials worn every day have perished. The history of textiles between the terminal dates of the Egyptian burying grounds and the 16th century tends to be divided into the history of vanished products based on documentary evidence on the one hand and the history of luxury silks on the other.

Among the rare textiles whose origin is known with certainty are those from the *tiraz* factories, which are inscribed with the names of the place and of the caliph in whose reign they were made. Some of these are tapestry-woven, most have embroidered inscriptions and date from the 8th–11th centuries.

**Western Europe.**—The Low Countries were the centre of a large and politically important cloth industry from the early middle ages. Already in the 8th century England was exporting wool to Flanders, but this trade did not become important till the 11th century. The Cistercians were important sheep farmers. Most districts in northern Europe made cloth of various qualities for

local consumption, but by the 12th century the Low Countries were weaving cloth from imported Spanish and English wool and exporting it to other parts of Europe. In the later middle ages English royal policy sought with some success to prevent the export of wool in favour of that of unfinished cloth. Flax was similarly grown and linen woven in a number of European countries, but the only linen textiles to survive in any number are the towels with decorative ends said to have been made in Perugia, It., in the 15th century. Silks and linens were also made in Germany, especially in Cologne and perhaps in Regensburg.

Silk was certainly being woven in Mediterranean countries by the 9th–10th centuries. Although at first raw silk was imported from the near east, the cultivation of the white mulberry tree essential to the silk worm soon followed. Some time after the establishment of the western caliphate in Spain (8th century) silk weaving was established in Córdoba; later it was carried to Almería, Saragossa, Málaga and elsewhere. In Hispano-Moresque textiles ornament from the near east was combined with a wholly distinctive style of decoration originating in Spain. Emphasis on the purely decorative form of interlacing patterns reached its climax in the last Moorish factories of Andalusia. The Norman conquerors of Sicily established silk-weaving workshops, but it is difficult to distinguish silks from Egypt, Sicily or Asia Minor for all drew on the same cultural sources. The traders of Venice and Genoa imported silks into the mainland whence they were distributed throughout Europe. An accessible source of raw material together with the early growth of compact city-states favoured the establishment of silk weaving in Italy. A treaty between Lucca and Genoa in the mid-12th century gave Lucca access to the Levant and also to the fairs in northern Europe. Merchants of Lucca traveled to the Levant to buy silk and to northern Europe to buy woolen cloths and to sell woven silks. In the 14th century, however, political difficulties displaced the town from its pre-eminence. Guilds of silk weavers were established in Venice, Florence, Bologna and Genoa.

A comparatively large number of silks can be attributed to northern Italy in the period from the 12th to 15th centuries, though few are known to come from any particular city. Their designs reflect the general style of Gothic art, with animals, rinceaux and heraldic devices of unfailing invention. During the 14th century the route to China was reopened, and many silks woven after that time incorporate decorative details showing Chinese influence—dragons, exotic birds, palmettes and cloud bands. Some of these may be seen in contemporary paintings; e.g., the robes worn by St. Edmund Martyr in the Wilton diptych (c. 1395) in the National gallery, London.

The technique with which these silks were woven was advanced; the main warp appeared on the surface of the textile and was combined with a second (or ground) weft to form a texture contrasting with that of the pattern. Damasks were woven, and during the 14th century velvet weaving was established. There were plain-cut pile velvets, cut and uncut pile together, voided velvets in which part of the ground was left without pile but brocaded, often with gold thread, and velvets woven with two heights of pile, sometimes further enriched with gold loops. Many 15th-century velvets probably made in Venice have survived as chasubles and copes.

Velvets with the typical curving pomegranate in silk pile and gold thread may be recognized in paintings both by Italian artists and by those of the northern schools—evidence of the popularity of Italian velvets in Germany and the Low Countries.

**4. 15th Century to the Industrial Revolution.**—A great variety of textiles have survived from the 16th century. Among woven textiles the silks produced under the Safavid dynasty in Persia are outstanding. The silks of this renaissance owed much to the stylistic tradition of Persian illuminated manuscripts in design, colouring and subjects depicted. Hunting scenes, animals, technique and splendid in effect with lifelike hunters, flowers, trees and birds, were rendered with accuracy and great decorative appeal. Several of the greatest were made in the court factories of Shah Abbas I (1587–1629). Persian treatment of

Fragment of incense-resist-dyed linen found in the burial grounds at Akhmim, upper Egypt; believed to date from the 9th–10th century A.D.

Linen chasuble, wood-block printed in black; Italian, dating from the end of the 15th century

Resist-dyed linen with a design showing Joshua and Caleb returning from the Promised Land; German (Rhenish), late 17th century

Diapered linen, block printed in black with a design said to represent Louis XIV and Madame de Fontanges; French, late 17th century

PRINTED TEXTILES: BLOCK-PRINTED AND RESIST-DYED LINENS

Cotton and linen, copperplate printed in purple. Other colours were added to the design by printing from wood blocks and by penning. By Robert Jones at Old Ford, 1769

Wood-block-printed cotton in madder colours. Blue added by hand penning. Printed at Fordingbridge, Hampshire, about 1790

PHOTOGRAPH BY C. H. CANNINGS FOR ENCYCLOPEDIA BRITANNICA

PRINTED TEXTILES: 18TH-CENTURY ENGLISH

Block-printed cotton from the factory of Christophe Philippe Oberkampf at Jouy, leading printworks in France during the 18th century. This piece, c. 1780

English cotton with pillar design, block printed on dark ground in madder colours, principally brown, tan and red; dating from about 1800

"L'Offrande à l'amour," copperplate-printed cotton by Jean Baptiste Huot, chief designer for Oberkampf, whose early designs were pastoral scenes, such as this one printed at Jouy about 1804

English cotton, plate printed in red; by Nixon and Co., Phippsbridge, Surrey, one of the leading English copperplate-printing factories. This piece dates from about 1770

PRINTED TEXTILES: FRENCH AND ENGLISH BLOCK PRINTS

BY COURTESY OF (TOP LEFT) ELINOR MERRELL COLLECTION, (TOP RIGHT) THE METROPOLITAN MUSEUM OF ART, ROGERS FUND, 1926, (BOTTOM LEFT) COLLECTION OF THE NEWARK MUSEUM; PHOTOGRAPH, (BOTTOM RIGHT) JACK SKEEL FOR ENCYCLOPEDIA BRITANNICA, INC.

Above: English roller-printed cotton by Samuel Matley, 1824. Roller printing greatly accelerated the output of printed textiles during the early 1800s.

Left: English block-printed cotton in madder colours from Bannister hall, Lancashire; 1836. Founded c. 1798, Bannister hall designs set the style for other textile factories.

"Honeysuckle," English block-printed chintz designed (1876) by William Morris, who revived textile printing as a fine art during the 19th century.

"L'Afrique," French block print on cotton and linen designed by Raoul Dufy for Blanchini F&F of Paris; dating from about 1924.

PRINTED TEXTILES: ENGLISH AND FRENCH BLOCK AND ROLLER PRINTS

floral design had a profound influence on European art but not on silk design until the period of its greatest inspiration had passed.

The Ottoman Turks also produced a fine series of silks in the 16th and 17th centuries. Brusa (Bursa) was the chief city weaving silks, though others are known. Turkish velvets were especially successful, owing their inspiration to those of Italy, though the designs were often treated on a larger scale.

In Europe Italian silks drew much from those of the 15th century, although by the late 16th century newer forms of ornament can be detected. More remarkable is the fine table linen produced in the Spanish Netherlands from the end of the 15th century (and perhaps earlier, though none survives). Special sets were woven to order for such clients as Henry VIII of England. Courtrai was the centre of the linen damask industry, though Haarlem became increasingly important in the 17th century. Damask cloths with napkins to match were woven with biblical scenes or coats-of-arms from the 16th century onward. Seventeenth-century damasks include commemorative designs, views of cities and some more original designs such as that of the cloth with a design of plates, knives and forks set for dinner, woven in Haarlem by Paschier Lamertin and now in the Victoria and Albert museum, London.

The War of the Spanish Succession at the beginning of the 18th century provided a rich source of subject matter, particularly beleaguered cities and equestrian portraits to commemorate the victories of Prince Eugene of Savoy and the duke of Marlborough. Such damasks were large, finely woven on a drawloom and expensive. Cheaper diapered or plain linen for napkins, cloths and sheets was also woven in great quantities in the same towns.

From the 17th century there survive some of the textiles made for a wider distribution than the court silks of Persia or the expensive Italian velvets. For those who could not afford the luxury of tapestries or silk hangings, certain northern towns in Italy made strong, coarse, woolen and hempen hangings. In the late 17th century this industry had shifted to Rouen and Elbeuf in France. Moreover during the 17th century the foundation of the English, Dutch and later French East India companies brought an increasing supply of cotton from Bengal into Europe for the making of fustians and other mixed fabrics. ("Cottons" until the 17th century and even later were usually low-grade woolen materials rather than true cottons.) The plantations in the American colonies were growing cotton for export by the second decade of the 18th century but probably little before then.

The establishment of important silk industries north of the Alps was a feature of the 17th century. While the woolen and worsted industries—the latter much developed in the 16th century—continued to produce the most important textiles in northern France, England and the Low Countries, the silk industry began to be significant in southern France. Although some silk had been woven in France in the 16th century and earlier, it could never compete with Italian imports. Under J. B. Colbert, minister of Louis XIV, however, the industries of Tours, Avignon, Nîmes and above all Lyons were supported by a rigorous policy of protection and the growth of raw silk was encouraged in southern France. The wars at the end of the reign of Louis XIV diverted French resources for a time from such capital investment, and during this period silk industries were firmly established in Holland and England. In London the industry spread from the City to the district of Spitalfields in the east, which greatly expanded with the industry in the first 60 years of the 18th century. Fine dress silks were woven by a large number of prosperous master weavers, many of them, especially the weavers of patterned silks, being of French Huguenot origin.

The London industry was subject to the general control of its medieval guild, the Weavers' company, but this exercised little influence on the types of silks produced. In France the Grande Fabrique de Lyon had a complex organization of regulations governing the qualities of the silks to be made and officials to enforce them. Wages were low and the economic regulations often in dispute, with an outright rebellion in 1744. It was

against a background of almost continuous social unrest and internal dispute that Lyons produced some of its most astonishing dress silks.

During the last years of the 17th century the designs of silks were transformed from the formal pomegranate pattern inherited from the 15th century and the stylized sprigs that persisted throughout the first 70 years of the 17th. Abstract curling forms, often in gold and silver thread on a crimson damask ground, erupted into gigantic bizarre designs with a profusion of motifs of disproportionate scale juxtaposed. Fashions changed with the season, and by the second decade of the 18th century the bizarre forms had given way to luxuriant but formal designs based on the outline of the old pomegranate motif but enriched with lacy diapered fillings. There was an increasing desire in the 1730s to give a three-dimensional form to the designs: a designer named Courtois succeeded in large floral designs by using tones of colour; Jean Revel (1684–1751) introduced *points rentrés* by which the tones of colour were dovetailed. A reaction toward naturalistic life-size sprays of flowers came in the 1740s, a period in which some of the most successful English silks were woven. From the middle of the century designs with bunches of flowers and trailing ribbons dominated all others. Neoclassical influence can be detected in the later 18th-century silk designs as in other media, laurel wreaths and plain stripes occurring frequently. A period of very dark colours in the 1790s was succeeded by a fashion for light colours and light materials, especially silk gauzes and cotton muslins. While such were characteristic dress materials, printed cottons often provided fashionable furnishings. In Lyons, however, Philippe de la Salle (1723–1803), designer and partner in a silk-weaving firm, designed a series of furnishings with lifelike birds, flowers, ears of wheat, etc., on a sumptuous scale.

The continuous change in fashion was perhaps stimulated by intense competition in the market for woven silks. Genoa never lost its markets for heavy velvets and damasks, Lucca survived until the middle of the 18th century, but in the general climate of mercantilism every sovereign tried to restrict the import of luxuries and to foster native industries. Silk industries were revived in Spain and founded in Berlin and even in Russia. A large number of Chinese painted silks were also imported into Europe.

It was not, however, until the 19th and 20th centuries that Chinese *k'o-szu*, silk tapestry-woven textiles, were appreciated in Europe. The dragon robes worn by the highest Chinese officials were not made known in the west till after the sack of the Summer palace in Peking in 1860. A few fine 18th-century examples survive and can be seen in all major museum collections.

Very high-quality woolen, worsted and mixed textiles were made in the 18th century for everyday clothing, linings and upholstery; they were still very expensive, however, and secondhand clothing was much worn by the poor in all countries. Although all cotton goods were prohibited, substitutes with a linen warp and a cotton weft were made both in England and on the continent of Europe, and in England were virtually indistinguishable from pure cottons. While these goods possibly reached unprecedented technical perfection, far-reaching technical changes began to appear in the cotton districts of Lancashire and the heavy woolen industry of Yorkshire.

**5. The Industrial Revolution.**—Kay's flying shuttle (invented in 1733) speeded up and therefore cheapened the production of plain textile goods. Quicker weaving increased the pressure upon the spinners to produce more thread than they could by the spinning wheel, virtually unchanged since the 15th century. It was, however, nearly half a century before Richard Arkwright's water frame (1769) and Samuel Crompton's mule (1779) began to replace the hand spinners with machines. These inventions and their perfection gave an incentive to mechanize the preparatory processes of carding and combing. The period from 1780 to 1820 produced a multitude of devices to mechanize each of the processes formerly performed by hand. The first power loom was improved upon soon after the turn of the century. Primarily these inventions made possible the mass production of cheap cottons, but nearly all could be adapted to wool.

The greatest technical problem in silk pattern weaving was the cumbersome and expensive drawloom. The elimination of the drawboy and the automatic weaving of the pattern were finally achieved by Joseph Marie Jacquard (1752-1834), who built upon the ideas of his predecessors. The Jacquard loom was widely used in France by the end of the first decade of the 19th century and elsewhere by 1820. For the first time it was possible to lessen the cost of textiles with a woven pattern. Although Jacquard was a silk weaver his loom was quickly adapted in the cotton and linen industries and by the weavers of shawls, an important new industry in Scotland and at Norwich, Eng.

**6. 19th and 20th Centuries.**—The break in the normal stylistic evolution of the patterns of woven textiles is not clearly evident before the 1830s. The eclecticism of the taste of the next half-century reflected a total change in outlook. Techniques and new materials were of paramount importance. Using new machinery it was possible for the first time to reclaim rag wool for shoddy, thus lowering the cost of woolen goods and providing good warm clothing for the new poor of the rapidly growing industrial towns.

Except in the extreme luxury trades (in which Lyons silks and St. Étienne ribbons in France led the other nations), the textile centres of Europe and the United States competed with one another to produce large quantities of ever-cheaper power-loom-woven materials. The manufacturers' pride in these goods—each patented variation was acclaimed as a new material—was shown in the great international exhibitions of 1851 and 1862 (London), 1867 (Paris), 1876 (Philadelphia), 1878 (Paris) and others hardly less important. The overloaded Victorian interiors of the newly prosperous made extensive use of every kind of furnishing textile, creating an ever-increasing demand. The multiplicity of uncoordinated patterns was especially marked in textiles and provoked a natural reaction. On the one hand, there were official attempts to found trade schools and schools of design; on the other, William Morris and his associates rebelled against the domination of the machine (*see* ARTS AND CRAFTS MOVEMENT). Morris himself founded a firm to make high-quality furnishing fabrics using traditional dyes, the best materials and artists' designs. Although its influence was not limited to England, the movement hardly affected the styles of commercially produced textiles until the end of the century. (*See also Printed Textiles, below.*)

The scientific advances of the 19th century, particularly in chemistry, produced not only new dyes but, toward the end of the century, new fibres. The disease and virtual extinction of the European silkworm left the silk weavers of Europe almost entirely dependent upon the far east for their raw material, hence the incentives to find a substitute were strong. The first textile filaments were made in France from nitrocellulose; in Germany the cuprammonium process developed, in 1892 British scientists invented viscose rayon. But none of these proved wholly satisfactory.

After World War I cellulose acetate was exploited commercially, and in 1946 the first of a new series of fibres no longer based upon the structure of cellulose was developed in the United States. This was nylon, the first of the polyamide fibres, greatly improved after World War II. The polyester fibres were first used in the 1920s. The best of the new man-made fibres produced textiles that were tough, washable, crease-resisting, hard-wearing and less likely than natural fibres to shrink, fade or feel. Drawing on relative supplies of raw materials they supplemented the four natural fibres very usefully but the warmth of wool, the coarseness of cotton and the elegance of silk were not easy to imitate. (*See also FIBRES.*) From the 1920s textile designs for the lighter-weight materials have been once more the work of artists and reflect the general taste of their period.

**7. Other Textiles.**—Certain textiles fall outside the main historical developments. Japanese silks, though technically similar to Chinese, represent a different idiom in design hardly known in the west until it suddenly became fashionable in the 1870s. The *kimono* woven by hand in parts of the United States preserved their traditional patterns throughout the 19th century. In some peasant communities of eastern and northern Europe in north

Africa and among the Indians of North and South America, textiles were hand woven until the 20th century. Such textiles were valued for their intrinsic qualities until the use of aniline dyes and their coherence by introducing alien harsh and garish colour schemes which quickly faded to a lifeless and uninteresting chrome.

## II. PRINTED TEXTILES

The term printed textiles covers all textiles patterned by the application of pigments—whether by printing, painting or by a combination of these methods. The pattern may be produced by painting on the cloth with a brush, by stencilling or printing from wood blocks, engraved copperplates or metal rollers or by screen printing, either with surface pigments or with dyes that penetrate the fibres of the cloth. The pattern may also be produced by "resist" or by mordant dyeing. In resist dyeing the resist paste or wax, which is impervious to the dye, is printed or painted on the material, covering the parts that are to remain uncoloured. In mordant dyeing, the parts that are to receive the colour are painted or printed with chemical substances known as mordants; when the fabric is immersed in the dye the colour is fixed on these parts, while washing removes it from the unmordanted areas. (These techniques are described at greater length in TEXTILE PRINTING.)

Printed textiles are believed to have been produced in the Caucasus as early as 2000 B.C. and there is no doubt that the art of ornamenting fabrics by painting or printing is of great antiquity. Painting was among the earliest methods of decorating textiles among the oldest surviving examples of this are some Greek fabrics, dating from the 4th century B.C., found in tombs in the Crimea, and also the well-known painted Egyptian mummy cloths. In these early painted fabrics surface pigments were used, but at least as early as the 1st century A.D. the process of mordant dyeing was known to the Egyptians and is described by Pliny the Elder (d. 79 A.D.) although no mordant-dyed Egyptian fabrics of this date appear to have survived. Before the Christian era India had a reputation for its resist-dyed and painted cottons. In China the art of resist dyeing was certainly known as early as the 7th or 8th century A.D., while indigo resist-dyed linens, several with rare figure patterns of religious subjects, have been found in the grounds at Akhmim, upper Egypt, and are thought to date from the 9th-10th century A.D.

In Europe, however, the art of textile printing does not appear to have begun much before the 12th century A.D. and the few pieces of printed fabrics of an earlier date that have been found in Europe appear to be of eastern origin. One of these is a piece of linen with a resist-dyed pattern of white circles on a blue ground, found in the tomb of Caesarius of Arles (c. 470-484) and preserved in the Nürnberg museum. A fragment of similar cloth printed in gold leaf with a design of a falconer on horseback was found in the grave of St. Cuthbert in Durham cathedral (c. 1104), but it is assumed also to be of eastern origin.

**1. Block-Printed Textiles.**—The earliest extant examples of European printed fabrics, dating from the late 12th century, are of Rhenish origin. The fabrics, of silk or linen, were printed from wood blocks with surface pigments, usually in black and red. A few of the oldest pieces are printed in more than one colour, usually black and red, and occasionally a third colour. The patterns appear to have been copied from the Byzantine and other eastern woven silks of the period. Although such fabrics seem to have been produced in considerable quantity and examples are numerous there is reason to doubt the authenticity of many of the surviving pieces.

**Early Development.**—In the 14th century the patterns of Rhenish printed fabrics were based on the woven silks from Lyons and Lucca. In one instance printed linen with a design of lions and stylized floral motifs (fragments of which are in the Victoria and Albert museum, London, and at Berlin) survives copied from the woven silk from which it was copied, a *chasuble* in the Stralsund museum in Germany. In the 15th century patterns copied from Italian velvets, with oval compartments containing stylized flowers or lobed pomegranate patterns, predominate.

printed fabrics dating from the 14th century have also been found and examples such as the famous tapestry of Simon the Sorcerer, showing scenes of dancers and horsemen on the Historisches Museum in Bern. Swiss, dating from the middle of the 14th century, show a high standard of technical excellence both in the cutting of the wood blocks and the actual printing.

Records of the Painter Stainers' company show that painting on cloth was a recognized trade in England as early as the 13th century. A probably the earliest surviving example, dating from the 15th century, is a burse from the parish church of Haselett, painted with the head of Christ and the symbols of the four evangelists.

By the 16th century simple block-printed fabrics appear to have been used in most European countries. A number of English examples of the Elizabethan period, copying the popular "black" embroidery or derived from contemporary lace patterns, have survived. Others, printed from engraved copperplates in ordinary printer's ink, were obviously intended as embroidery patterns. The 17th century saw considerable advances; in Germany, for instance, the patterns consisted on the one hand of floral designs not derived from woven sources but characterized by the beveled and elaborate cutting of the wood blocks, and on the other hand indigo resist-dyed linens, often with pictorial and religious subjects, which were copied from the contemporary linen designs.

### 2. Origins of the European Calico-Printing Industry.—

The chief advances in textile printing were the result of an attempt by European textile printers to imitate the fast-dyed, hand-printed Indian cottons that began to be imported into Europe during the early 17th century. It was not until the 1670s, however, that the European calico printers appear to have been successful (more or less simultaneously in France, Holland and England) in mastering the complex problems of mordant dyeing with madder, the basis of the imported Indian chintzes. Since "calico," the general term for cotton cloth of all kinds imported from the east, was also soon used to describe various cotton fabrics of European manufacture (including those with linen warps), textile printers came to be described as calico printers rather than, as in earlier times, as linen or stuff printers. Calico printing was to an extent common in most European countries during the 18th and 19th centuries but England, France, Holland, Switzerland and Germany were the only countries where the industry achieved any real importance.

The English calico-printing industry appears to have been founded by William Sherwin, an engraver, who in 1676 was granted a patent for a "new way of printing broad calicoes" and set up a printworks at West Ham, east of London on the river Lea. Other printworks followed and by the end of the century the industry was well established. Indeed by 1696 the industry had already grown strong enough to arouse the established silk and wool interests. A law of 1700 prohibiting the import of Indian chintzes was followed by laws of 1712 and 1714 which placed heavy excise duties on hand-printed chintzes. Finally in 1720 a law was passed that prohibited printing on all cotton cloth, but the calico printers were able to evade the intention of the law by printing on cloth with a linen warp and cotton weft. It was not until 1754 that the ban on printing was raised from all cotton and not until 1831 that the heavy excise duties were finally removed. In spite of these restrictions the English calico-printing industry continued to expand and flourish.

In France the calico-printing industry was even more hampered by restrictive legislation than in England. An edict of 1686 forbade not only the wearing of imported Indian chintzes but their importation. Although it was widely evaded the industry made real progress until the final removal of all restrictions on calico printing in 1759. Even before the lifting of the ban, however, a number of calico printworks had come into operation, including those of Koechlin Schmalzer and Dollfus at Malthouse, the Danton brothers at Angers (1753) and John Rudolph at Orange (1758). Wetter, a rich Swiss merchant, had established a printworks at the free port of Marseilles

Although simple block-printed textiles had been produced earlier in Holland, the first successful attempts at imitating the imported Indian chintzes were made at a printworks at Amersfoort set up in 1674 by two Amsterdam merchants and a Dutch living in Holland. Other factories followed and by the middle of the 18th century about 150 printworks were in operation, mainly in Amsterdam and the surrounding districts. The number of printworks, however, gradually declined, largely as a result of increasing French and English competition, and by 1800 only four were in operation. In the following years Belgian printworks supplied most of the exports to the Dutch colonies in the East Indies, but after the separation of Belgium and Holland in 1830 new printworks were established in Holland, forming the nucleus of the modern textile-printing industry in that country.

In Germany during the late 17th and 18th centuries Augsburg was the chief centre of textile printing. Resist-dyed linens and block-printed linens printed in black or red are found but in order to protect the linen industry, printing on cotton was prohibited until about the middle of the 18th century. Among the most important German printworks was that of the brothers Neuhofer at Augsburg, which operated in the early 18th century, and that of Johann Heinrich Schiele, who is said to have introduced copperplate printing into Germany in 1766.

Switzerland was an important textile-printing centre throughout the 18th and 19th centuries. Block printing by the "application" method, which involved the use of watered colours (dye and fixing agent mixed together), had been practised in Switzerland since the 16th century, and although this method continued into the 19th century the resulting prints were not fast to light or soap and water. The *indiennes* industry of Switzerland, however, developed from the processes of indigo and turkey red dyeing rather than from block printing as such, and was introduced by Swiss printers who had worked in Holland and by French Huguenot refugees. The first printworks in Geneva was founded in 1687 by a group of local merchants and a Frenchman named Matthieu Marin. Other printworks followed and by about 1720 Geneva was an important calico-printing centre. During the latter half of the 18th century, however, the industry declined and by 1815 only two printworks remained in operation; by 1830 the Geneva industry was virtually extinct.

The calico-printing industry of Zürich was founded by David Esslinger in 1720, while that of Basel was founded in 1716 by Samuel Rybinger, who had learned his trade in Holland. The most important centres of calico printing in Switzerland, however, were the cantons of Neuchâtel and Glarus. The first Neuchâtel calico printer was Jean Labran, who opened a printworks at Pré-Royer in 1715. By 1750 several others had come into operation. One of the largest was that of Du Pasquier and Portales at Cortaillod, established in 1750 and by the beginning of the 19th century the largest in Switzerland, comprising more than 300 printing tables and a considerable number of roller-printing machines. The first calico printworks at Glarus was established in 1740 by Johann Heinrich Streitli, and the Glarus industry reached its peak in the 1840s.

Little is known of the Italian printworks apart from those in the Genoa area which specialized in the production of *messeri*, large decorative panels copied from Indian models, the so-called "tree of life" being the commonest design. The most important factory was set up at Sampierdarena in 1787 by Michael Speich, a Swiss from Glarus, together with his cousin Luigi Testori, who succeeded to the business about 1830.

The earliest reference to calico-printing in America is an advertisement in the *Boston News Letter* of April 23, 1712, stating that a certain George Leason from England, together with a Boston clothier named Thomas Webber, had set up a printworks near the bowling green. Although similar advertisements are found with increasing frequency, it was not until the last quarter of the 18th century that textile printing can be said to have become an industry in the United States. One of the most important figures was John Hewson, an Englishman who, encouraged by Benjamin Franklin, set up a calico printworks in Philadelphia in 1774. His work was interrupted by the American Revolution, but he was able to re-

sume his activities in 1789 with the assistance of a loan from the government. Although his output was considerable, and comprised both dress and furnishing fabrics and printed handkerchiefs, practically nothing has survived that can be attributed to him, although he is said to have printed a fine coverlet now in the Philadelphia Museum of Art. His factory lasted until sometime in the 1820s, the business being carried on by his sons. Among other 18th-century American printworks was that set up about 1790 at East Greenwich, R.I., by Herman Vandausan, a textile printer from Mulhouse. Other Rhode Island printworks included that of Schaub, Tissot and Dubosque (1794), and by 1840 there were 17 dyeing and printing establishments in that state.

Calico printing was also carried on in Massachusetts and New York. The first roller-printing machines in America were introduced in 1810 at the factory of Thorp, Siddall and Co. near Philadelphia, Pa.

**Designs.**—Although certain factories specialized in particular classes of goods, the general development of design in printed textiles was much the same throughout Europe and the United States, with the English and French printers taking the lead. Since surviving English and French textiles are far better documented than those of other countries, the general trend of design can best be studied by those examples.

The earliest surviving European examples were mostly printed in the limited palette of black, reds, purples and brown obtainable from madder dye, and the designs were often free adaptations of Indian floral patterns. Most of the earliest examples survive as linings to late-17th-century leather trunks or as linings to silk coats, stomachers and embroidered bags or purses. An important collection of impressions from early 18th-century textile printers' wood blocks survives in the Berch collection at Nordiska Museet, Stockholm, which are mostly single- or two-colour prints mainly of floral designs, characterized by fairly elaborate cutting of the wood blocks. Though knowledge of these early European fabrics block printed in the madder style is fragmentary and uncertain, it is clear that by the middle of the 18th century at the latest the European printers were able to add indigo blues and weld yellows to the basic madder colours, either printed by block or painted or "penciled" with a brush, and that by this time the printed fabrics had achieved a status that enabled them to exist in their own right, not merely as cheaper substitutes for woven fabrics.

A folio volume in the library of the Musée des Arts Décoratifs, Paris, contains 13 samples of English chintz, collected by John Holker in Lancashire in 1750 and presented to M. De Montigny of the French Royal Academy of Sciences. These samples, which are quite unfaded and fully annotated, show that by this time the English calico printers were able to produce well-drawn floral designs using the full range of colours obtainable from madder dye, together with indigo and weld yellow. Supplementary evidence of the skill of the English calico printers at this time is found in a series of original designs and impressions from wood blocks (in the Victoria and Albert museum) by John Baptist Jackson, who worked as a calico printer for a few years before he set up as a wallpaper manufacturer in 1752.

**3. Copperplate-Printed and Later Block-Printed Textiles.**—In the middle of the 18th century, the introduction of copperplate printing radically transformed the appearance of European printed textiles by allowing a fineness of detail and delicacy of drawing that had not been possible with the comparatively coarse technique of wood-block cutting. Copperplate printing on textiles was invented in 1752 at the Drumcondra printworks, near Dublin, by Francis Nixon, who introduced the technique into England within the next four years. For the next two decades—apart from the short-lived factory of Gayet and Montgirod at Sèvres, France, which survived for only 18 months in 1760–61—Ireland and England retained a virtual monopoly of the new technique. From the beginning the technique of copperplate printing was admirably suited to the production of large-scale pictorial designs, with a repeat of about a yard square, covering a wide range of subjects including pastoral, mythological and theatrical scenes, *chinoiserie*s and subjects commemorating important military and political

events. It was also widely used for finely engraved floral designs for both dress and furnishing fabrics. Few documented Irish examples have survived but pattern books (in the Musée de l'Impression sur Étoffes, Mulhouse, and the Victoria and Albert museum) containing over 400 different impressions from English calico printers' copperplates, as well as a vast quantity of extant plate-printed textiles, testify to the excellence of the English productions. Although a number of the English pictorial designs have certain affinities with the French *toiles de Jouy* (see below), a particularly striking group of designs with large flowers and birds seems to be especially characteristic of the English printers.

The copperplate designs were almost invariably monochrome, being printed either in blue, red, purple or sepia. One English factory, that of the Wares at Crayford, is known to have printed in copperplate in two colours. In a few instances, such as the textile printed by Robert Jones at Old Ford in 1769 (Victoria and Albert museum) and the "volunteer furniture" printed by Edward Clarke at Palmerstown, Ire., in 1783 (National museum, Dublin) additional colours were added to the basic copperplate design by printing from wood blocks or by hand painting.

Although evidence has shown that generally speaking the English surpassed the French in copperplate printing, the credit for its development previously was given to Christophe Philippe Oberkampf and his factory at Jouy. Oberkampf, the son of a cloth printer and dyer, was born in Germany but moved with his father to Aarau and acquired Swiss nationality. After working first at the Cour de Lorraine factory at Mulhouse and then at the Arsenal at Paris he set up a small factory at Jouy-en-Josas, near Versailles, where his first print was produced on March 1, 1760. Four years later, in 1764, new buildings were begun and, owing to Oberkampf's unrivaled technical skill combined with his flair for singling out the best French designers, Jouy became the foremost printworks in France. The productions ranged from small, block-printed designs for dress fabrics to large-scale pictorial prints for furnishings.

According to the biography of Oberkampf, the secrets of copperplate printing were brought to Jouy in 1770 by his brother Frédéric, who had seen it in use at Morat, near Neuchâtel in Switzerland. However, no surviving Jouy copperplate prints can be positively dated earlier than 1783, the date of the famous *Travaux de la Manufacture*. This design was the work of Jean Baptiste Huet, who became the factory's chief designer. Most of Huet's early designs were of pastoral scenes, such as "Offrande à l'amour," "La Fête de la fédération" and "Les Plaisirs de la ferme." After the Revolution Huet followed the general trend toward classicism and produced a series of designs in the Directoire style including the "Scènes Pompéiennes" and "Le Loup et l'agneau." Examples of his work can be seen in the Musée des Arts Décoratifs, Paris. Other prominent designers who worked for Oberkampf were Hippolyte le Bas, who specialized in architectural subjects such as "Les Monuments de Paris," and Horace Vernet, who specialized in hunting scenes. Although Oberkampf's reputation was such that the term *toile de Jouy* became a generic description for all copperplate textiles, other French factories produced designs of equal distinction, among them the firm of Favre, Petitpierre et Compagnie (founded 1760) at Nantes and that of J. P. Meillier at Beautiran, near Bordeaux (founded 1792).

The introduction of copperplate printing did not, however, eclipse wood-block printing, and the two techniques developed side by side. The most popular wood-block designs continued to be floral, including designs based on the successive fashions in 18th-century woven silks. There is little basic difference between the wood-block-printed chintzes of the 1760s and 1770s, but in the 1780s several different styles emerge, including coiling floral designs with broken stems based on Indian models and large-scale arborescent designs often incorporating birds. Two parallel styles are especially characteristic of the last decade of the 18th century: first, designs on an almost black madder ground with delicately drawn mossy trails, which in England were popular for both dress and furnishing fabrics though in France they seem to have been limited to dress fabrics; second, designs of alternate vertical

stripes, one on a white ground, the other on a dark, which were equally popular. This second type was virtually limited to England, while France favoured designs of detached sprigs of flowers, ears of wheat and insects, characterized by fine and precise cutting of the wood block.

Although finely engraved copperplate prints continued to be produced in France until the early 19th century, copperplate printing was in decline in England by that time. Most of the English factories that had specialized in copperplate prints were in London or the home counties. Among the most important were Robert Jones (c. 1760–80), Old Ford; Nixon and Co. (c. 1752–89), Phippsbridge, near Merton, Surrey; Bromley hall (c. 1740–1823), Middlesex; John Munns (c. 1769–84), Crayford, Kent; and Joseph and Mary Ware (c. 1760–81), Crayford.

Calico printing in Lancashire was established about the middle of the 18th century with an important offshoot in Carlisle, and from the onset the Lancashire and Carlisle printers concentrated on the production of wood-block-printed chintzes. By the beginning of the 19th century, most of the London copperplate printworks had closed down and with the shift of emphasis to Lancashire wood-block prints predominated. The leading factory in the production of high-class wood-block "furniture" prints was that at Bannister hall (founded c. 1798), near Preston, Lancashire, which, under successive changes of ownership, remained in operation until 1893.

The Bannister hall records dating from 1799 to 1840 include a continuous series of about 3,800 documented samples of printed cottons supplemented in most cases by the original designs, which provide an invaluable and accurate guide to the prevailing styles throughout those years, particularly since Bannister hall set the fashion for the other factories.

By 1800 the dark-ground style had given way to the so-called drab style, printed in yellow, olive, brown and buff, and the meticulous drawing of the 1790s was replaced by a broader technique with coarser cutting. The French copperplate *Directoire* prints were paralleled in England by a brief fashion in the years 1804–06 for "classical" and "Egyptian" designs, printed in hot "Pompeian" colours, and for *chinoiserie* designs incorporating figures, buildings and vases; "Indian" designs on bright-red grounds were also popular. Among the other wood-block styles popular in the early 19th century were designs incorporating game birds and architectural features. Panels printed for incorporation into patchwork quilts were produced in considerable quantity in the years around 1815.

**4. Roller-Printed Textiles.**—Although roller printing was invented by Thomas Bell as early as 1783 and was certainly used in the production of small-scale dress patterns by the beginning of the 19th century, it had little general effect on the design of printed textiles until about 1815. Thereafter in England the technique was used for pictorial prints, often of scenes of hunting and other sports and pastimes, but the designs were generally cruder than those of the 18th-century copperplate prints. In France the technique was widely used for a vast range of pictorial designs, often with diagonally hatched or finely diapered grounds.

From the 1820s onward the development of roller printing led to a vast increase in the output of printed textiles, although high-class furniture prints continued to be printed by wood block in the traditional madder style. In the 1820s the standard of engraving on the metal rollers was often extremely high. The actual engraving of the rollers was generally done not by the printers themselves but by special firms. One of the leading firms of engravers was Joseph Lockett of Manchester (later Lockett, Crossland), which supplied engraved rollers not only to the English calico printers but to printworks throughout Europe. This firm was largely responsible for the "fancy machine grounds" or "cover rollers" in which the whole background of the fabric was covered with elaborately engraved diaper patterns.

These enjoyed a considerable vogue in the 1830s and were often used as a background to the traditional, wood-block-printed floral chintzes.

**5. Decline and Revival of Textile Design.**—Until about

1810 all printing, with the exception of low-grade fabrics printed in fugitive colours, was based on the use of vegetable dyes, which in practice meant madder, indigo and quercitron. From then on, however, the competitive efforts of the French, German and English chemists resulted in a series of new chemical resists and discharges for transforming the appearance of the old vegetable dyes, and new methods for the use of colours such as prussian blue, cochineal pink and catechu brown. In addition, a completely new range of mineral dyes, including manganese brown, chrome yellow and antimony orange, and a "solid green" were placed at the disposal of the textile printers. These new discharges, resists and mineral dyestuffs had brought about a radical change in the appearance of printed textiles more than 20 years before W. H. Perkin's discovery of the aniline dyestuffs in 1856.

The combination of the indiscriminate use of these new colours, which were eminently suitable for roller printing, and a lower standard of engraving and design led to a gradual deterioration in printed textiles that was increasingly apparent from 1835 onward. A vast amount of cheap, roller-printed fabric was turned out by the English and European printers in a great variety of styles, ranging from floral designs and elaborate pictorial prints of romantic and sentimental subjects to various exotic styles intended for overseas markets. The eclecticism of the designers knew no bounds, and the 19th-century "battle of styles" was reflected in printed textiles that combined rococo, Gothic and classical elements with paisley motifs, tartan ribbons and a host of miscellaneous ornament. Even so, throughout the 1840s and 1850s, both the English and French and particularly the Alsatian printers continued to produce well-drawn floral chintzes, printed by wood block in the madder style, for the high-class furniture trade. Many of these were printed on challet, a fine worsted wool, instead of on cotton, which gave an added richness and depth to the colours. Although the Alsatian printers maintained a high standard of technical excellence, little of distinction was produced throughout the 1860s and 1870s.

The revival of textile printing as a fine art and the revival of the decorative arts generally that came about in the later 19th century must largely be credited to William Morris. Morris produced his first design for a printed textile in 1873, the first of 44 different designs for chintz, all of which were printed by hand with wood blocks and, with one or two exceptions, with vegetable dyes. Several of his finest chintzes, including the well-known "Strawberry Thief" (1883), were printed by the laborious and obsolete method of indigo-discharge printing. There is little doubt that the Morris chintzes printed first by Sir Thomas Wardle at Leek, and later at Morris' own workshops at Merton abbey, are among the finest printed textiles of all time.

The 1870s also saw the production of printed textiles influenced by Japanese art, with highly stylized flowers whose flat symmetrical petals were set against fretted backgrounds. In the 1880s a heavily textured cotton known as cretonne and velveteen were much used for printed furnishing fabrics, while some of the finest dress fabrics were printed on silk. From 1880 onward there was an increasing tendency for textile printers to commission designs from leading architects, artists and professional designers, which did much to raise the general standard of production. Throughout the latter part of the 19th century and the 20th century, the styles in printed textiles have closely followed the general development of the decorative arts. In the years around 1900 the influence of Art Nouveau (q.v.) was apparent, and outstanding printed textiles in this style were produced by firms such as Liberty of London.

In the 20th century modern movements in painting and the influence of the Ballets Russes and the Bauhaus in Germany led to the development of geometrical and abstract designs, usually printed in strong, vivid colours, often emphasized by black outlines. In England the move toward abstract design was fostered by the Omega workshops, founded by Roger Fry and a group of artists, for whom in 1913 the Maromme printworks of Rouen produced a series of printed textiles. A leading firm that did much to popularize the new styles was that of William Foxton, who from 1917 commissioned designs from leading artists including Charles

Rennie Mackintosh and Claud Lovat Fraser. In France outstanding printed textiles were produced by the firm of Bianchini Ferrier to the designs of Raoul Dufy and other painters. The later 1920s and early 1930s saw a return to more subdued, pastel colours and floral designs, characterized by overlapping segments and highly stylized flowers. This style achieved widespread currency at the Paris exhibition of 1925.

**6. Screen-Printed Textiles.**—In the 1930s the development of screen printing finally removed all restrictions from the designer and allowed enterprising manufacturers to try out short runs of experimental designs without incurring the heavy expense of engraved rollers or resorting to the laborious process of hand-block printing. This has resulted in an ever-increasing variety of design in printed textiles and at the same time extended the practice of commissioning designs from artists rather than professional designers.

Between World Wars I and II there was an important revival of hand-block printing in England on the part of a number of artist-craftsmen who produced both dress and furnishing fabrics, designing, cutting and printing the blocks themselves. Most of these fabrics had simple patterns produced in dark low tones, often with vegetable dyes, no doubt as a reaction against the garish colours and elaborate designs of the mass of commercial production.

In most countries there was little advance in the design of printed fabrics during World War II but after the war the development of mechanical screen printing brought an even greater variety of printed textiles. In the postwar years Scandinavia achieved a considerable reputation for printed textiles. Danish manufacturers were pre-eminent in the development of floral design, while Sweden and Finland tended to concentrate on crisp, geometrical patterns. With modern printing techniques the translation of any type of design onto cloth is possible. In contemporary screen-printed fabrics the designs range from abstract patterns imitating the work of avant-garde painters to elaborate florals, often with huge-scale repeats.

**7. Oriental Textiles.**—*Persia.*—The block printing of textiles in Persia may be traced back certainly to the 17th century. The journal of Jean de Thévenot (1633–77), *Relation d'un voyage au levant*, describes fabrics in which "the flowers and other paints are stamped upon them with a mould besmeared with colours." The French traveler Jean Chardin, in his *Voyages en Perse* (published in 1686), describes not only the painted cloths, similar to those from India, but also taffetas and satin, block printed with gold and silver with calligraphic, floral or pictorial designs. Painted and printed textiles produced in Persia were exported to Europe to the East India company in the late 17th and 18th centuries, and although records describe the textiles as "perses" it seems that little distinction was made between those of Indian and Persian origin.

Persian textiles of the 18th and 19th centuries with patterns produced by a combination of block printing and hand painting survive in considerable quantity in the form of wall hangings, prayer mats, curtains for doors or niches, bed coverings and shrouds. Most of the designs are floral but incorporate pine cone and other decorative motifs.

*China.*—Chinese resist-dyed silks, dating from the 7th or 8th century A.D., are preserved in the Shōsō-in, the imperial treasure house at Nara in Japan, and similar fragments were discovered by Sir Aurel Stein in eastern Turkestan. From the 18th century onward floral patterns painted in body colour on silk were made for export to Europe to be made up as dresses or hangings. A number of ecclesiastical vestments of Chinese painted silk dating from the 18th century also survive.

*Japan.*—It is probable that the Japanese learned the art of resist dyeing from the Chinese. A fragment of Japanese silk stenciled with the Buddhist sacred wheel is believed to date from the 8th century, and stenciled patterns are generally characteristic of Japanese work. Block printing was also practised in Japan and included a method known as negative block printing in which the hollowed-out parts of the block, not the relief portions, are charged with colour. The form of resist dyeing known as tie-and-dye

work was extensively practised in Japan, as well as in India, China and other parts of Asia, and in Africa. In Japan this was known as the *shibori* process, and in the 18th- and 19th centuries examples the process is often combined with embroidery.

(B. J. Mo)

**Javanese Batik.**—Batik is a Javanese word applied to the wax resist technique of pattern dyeing on cloth, as practised there. Those parts of the cloth not required to take the dye are covered with hot wax, after which the whole fabric is dipped in the dye vat, an operation repeated according to the number of colours in the pattern.

It is doubtful if any batiks preserved in museum collections date from before the 1750s, and therefore little is known about the origins of this technique in Java. However, there is evidence that a simplified batik technique (possibly copied from India) was widely practised independently in southeast Asia: the Toradjas of Celebes (Sulawesi), for instance, until the second half of the 20th century produced simple batiks, applying the hot wax by means of a narrow, flattened strip of bamboo.

The decisive advances in Java, probably in the 18th century seem to have resulted from the invention of the *tjanting*, a small copper crucible with a bamboo handle and a projecting spout for applying the wax.

In *tjanting* dyeing the cloth is elaborately washed and soaked to secure the right texture and surface and is then hung over a frame, the artist, usually a woman, sitting cross-legged before it. The design is sometimes first sketched in charcoal, but the best artists use only their *tjantings*, relying on visual memory. They outline the area that is to be dyed and cover the rest of the surface with wax. The cloth is turned over and the operation repeated on the other side. The cloth is then immersed in cold water till the wax hardens and is afterward dipped in the dye vat. The wax is removed, leaving exposed other parts of the cloth to be dyed different colours by the same process. The traditional colours are indigo blue, madder red and brown; secondary colours are produced by dyeing one colour over another.

In the 19th century copper-mounted wood blocks for applying the wax to the cloth were introduced. This, known as *tjap* printing, has almost entirely superseded the more laborious and highly skilled *tjanting* process. Batik was traditionally used almost entirely for clothing.

### III. INDIAN TEXTILES

From early historic times India was famed for its textiles. This is known from literary and archaeological evidence, although very few fabrics of a date earlier than the late 16th century survive. The decorative techniques traditional from early times are embroidery, resist dyeing, hand painting (with mordants) and block printing. A wide variety of materials have been employed for weaving but the one most commonly used was cotton. Excavations at Mohenjo-Daro have shown that cotton was woven at least as early as the 3rd millennium B.C. The few minute fragments discovered owed their chance survival to impregnation with silver salts, absorbed from the walls of the silver vase in which they had remained for at least 4,000 years. Traces of purple dye, thought to be madder and therefore suggesting an early knowledge of dye chemistry, add to the significance of the discovery, while the numerous spindle whorls found at the same site—some of crude pottery and others of more expensive faience—suggest that spinning was practised extensively and by all classes. Contemporary sculptures and terra-cottas show that at least two articles of costume for which India became famous, the girdle and the shawl, were already worn at this period.

Evidence is lacking for the thousand years following the collapse of the ancient city-states of the Indus valley; but the Greek physician Ctesias, writing in the early 5th century B.C., mentions the popularity of brightly coloured Indian textiles among the Persians, an indication that Indian fabrics were being made for export at least as early as this period. It is not known when they first reached Europe, but the use of the oriental word *basina* (Sanskrit *karpasa*) for cotton in the *Pausimachus* of the 1st century A.D. Strabo, on the

Porphy of Megasthenes (c. 300 B.C.), recorded the Indian love of colour and ornament, and added, "Their robes are worked in gold and ornamented with precious stones, and they also wear patterned garments of the finest muslin."

During the 1st century A.D. Indian muslins became famous in Europe under such names as *nebula*, *gangetika* and *venti* textiles ("woven winds"), the latter exactly translating the technical name for a special type of Dacca muslin still being made in Bengal in the 19th century. Silk was also an important export to Rome, both as yarn and as finished cloth, but the author of the *Periplus of the Erythraean Sea*, written sometime between A.D. 50 and 130, makes it clear that the raw material was imported into India from China. Wild silks had been woven in India before this, but there is no proof that the domesticated silk-reeper was introduced into India from China before the medieval period.

Although there is no specific mention of dyed cottons in the *Periplus*, excavations at the site of the Indo-Roman trading station at Arikamedu, near Pondicherry, have revealed that large-scale dyeing operations were undertaken in the immediate vicinity of the port. Further proof that the Indian dyer was already famous in the Roman world for his skill is indicated by a reference in St. Jerome's 4th-century Latin translation of the Bible, Job being made to say that wisdom is so enduring that it "may not be compared with the dyed colours of India." There is also evidence that by the 8th century A.D. Indian dyed cottons were known in England, for Bede records in his *Life of St. Cuthbert* that the Bishop of Clovesho forbade priests to wear clothes *tinctae Indiae coloribus* ("dyed with Indian colours").

Indian textiles of the medieval period can be studied in some detail from the Ajanta wall paintings (particularly those attributed to the 6th century A.D.). Apart from embroidery, at least four distinct techniques can be identified: *bandhana*, or ordinary tie-and-dye work; double tied-resist dyeing (*ikat*); brocading; and the muslin weaving.

From the 12th century onward Indian dyed cottons were exported in bulk to Egypt, and many such pieces have been recovered from the sites of old urban rubbish dumps, especially at Al Fustat (near al Qadimah), the exceptionally dry climate accounting for their preservation. These are the oldest Indian patterned fabrics surviving.

From earliest times there have been two distinct weaving traditions in India. The first was the domestic one, practised in every village up to the 20th century and mainly concerned with meeting local needs. The second was the more specialized tradition of commodity production, mainly concentrated in or near market towns and characterized by guild organization. Whereas in the earliest literary records (such as the Rigveda) the weaver is feminine, the development of commodity production in the 1st millennium B.C. seems to have established professional weaving as an exclusively male occupation. During the 2,000 years between the Vedic period and the decline of the handloom industry in the 19th century the main areas of commodity production remained the same. They are described in the *Periplus* in much the same terms as they were described by travelers of the 17th and 18th centuries. These main areas were: the west of the subcontinent with Gujarat, Sind and Rajasthan as the focus; south India, comprising the Coromandel coast as it used to be known, stretching from the Krishna delta to Point Calimere; and the lower Ganges valley between Varanasi (Benares) and the Delta. The main reason for this disposition of the industry was of course geographical. Each of the three areas could offer ports suitable for foreign shipping, and also comparative ease of inland communication.

From the 16th century onward Indian pattern and design were heavily influenced by Persia. This influence reached India in the first place through Islamic court fashion; but by the 17th century it had spread to the villages. Many of the sprigged patterns and floral diapers so characteristic of the Indian block printer's art of the later centuries were derived from Safavid Persia. The history of mordant printing with blocks (as opposed to the application of dyes by brush) is complicated, and it is not possible to establish

with certainty that the former technique was practised in India before the period of Islamic influence. The balance of available evidence suggests that the technique of mordant printing with blocks reached India about the 17th century from Turkey.

One of the oldest traditional techniques of textile decoration and one that has been very widely practised in India is *bandhana*. Portions of a silk or cotton cloth are tied tightly with wax thread before the whole cloth is dipped in a dye vat; the threads are afterwards untied, the parts so protected being left uncoloured.

The technique of *ikat* or double-resist dyeing, in which warp and woof are dyed separately by the tie-and-dye process before weaving, was practised in Orissa and the Deccan as well as in Gujarat. At Patan, in Gujarat, which produced the finest work of this kind in silk, such fabrics, known as *patolas*, were used especially as marriage saris. They were also extensively exported to southeast Asia from the 12th century onward, giving rise to many imitations in those countries.

The main centres of brocade weaving were Varanasi, Ahmedabad and the Deccan. The brocades for which India has been especially famed are woven silks in which part of the pattern is distinct from or supplementary to the wefts. Those woven in pure silk are called *amrus*, those with gold or silver thread in addition to silk, *kimkhab*s (Anglo-Indian, kincob).

Another form of brocading for which India was especially famous is the cashmere shawl. In this the technique corresponds to what in Europe would be called the twill-tapestry method. Coloured wefts are inserted by means of floating wooden bobbins on a simple loom. The weft threads alone form the pattern and do not run the full width of the cloth, being woven back and forth round the warp threads only where each particular colour is needed. The finest cashmere shawls were made of *asli tus*, the fleece from the underbelly of a particular species of wild mountain goat; the majority of shawls, however, were woven with the fleece of domestic goats, usually mixed with wool. The origins of the cashmere industry are obscure but can be traced back at least to the 15th century. Cashmere shawls were extremely fashionable in Europe between 1780 and 1880, during which period many European imitations were made on both drawlooms and Jacquard looms, especially at Norwich (Eng.) and Paisley (Scot.) and at various centres in France. The European imitation is always distinguishable from a cashmere original by the fact that in the latter the weft threads are inserted in the tapestry method and only for that portion of the required colour, not for the full width of the cloth.

Between 1600 and 1800 silk and cotton textiles were exported in large quantities from India to Europe mainly through the agency of the Dutch, English and French East India companies. The three classes of piece goods most in demand for this trade were plain-woven cottons (sold in competition with European linen), hand-painted cottons or chintzes (much coveted in Europe because of the brightness and permanence of their colours) and silk or mixed silk and cotton fabrics mainly used as dress materials. These goods were usually commissioned according to patterns sent out from Europe in the first place, but in the process of copying or adaptation the Indian craftsmen often infused an exotic spirit into the designs that actually increased their appeal in Europe. The importance of this trade is testified by the number of Indian textile terms assimilated into the English language: chintz, palampore, pajama, seersucker, dungaree, shawl and so on.

**TEXTUAL CRITICISM**, a general term for the application of logical method to analyzing the relationship between preserved and inferential forms of a text, followed by the application of various techniques, including critical judgment, designed to establish what will ordinarily be the single definitive form of the text.

This article is concerned with general principles of textual criticism, particularly as they apply to the study of literature. For a related discussion, see **BIBLIOGRAPHY: Textual Bibliography**. For a detailed consideration of the critical problems posed by variant manuscript texts of the Bible and variant codices of the Old and New Testaments, see **BIBLE and BIBLE, TRANSLATIONS OF**.

### CLASSIFICATION OF TEXTS

By "text" is meant a series of word forms inscribed in a language known, more or less, to the inquirer, and assumed to have a meaning that has been or can be ascertained. Thus, decipherment or recovery of meaning from inscriptions in lost tongues is not textual criticism. Texts may be preserved in autograph or in transmitted form. Transmission may be as close as the immediate copy of an autograph, or as distant as copies of copies to any degree; moreover, texts may be transmitted in written or in printed form (each generally defined) or in both. "Transmitted" texts share only one characteristic: their preserved forms are not written out by the author in any manner. When there is mixture, the transmitted and autograph parts are to be distinguished. In some few cases the problem of oral transmission will arise to complicate the usual written or printed line of transmission.

**Autograph v. Transmitted Texts.**—In its purest sense, "autograph" has traditionally been applied only to a document in the writing of the author. Some critics have argued that whatever has been attested or revised by the author, though in the writing of another, may also be included under autograph; but this position is impractical. If a copy made by an intermediary could be assumed always to be absolutely exact, or the review of the author that of a strict and accurate collator so that his attestation or revision carried the guarantee that in no respect did the whole derived document vary from its original in his own writing, the broader definition might be acceptable. But common experience shows that neither requirement is ordinarily met, and hence approval by an author of a nonautograph copy can under no circumstances bestow on that copy the authority inherent in a true autograph original; nor can authorial revision extend specific autograph authority further than the autograph revisions themselves.

In fact, textual criticism is accustomed to treat questions of authority with considerable literalness, and does not confuse what is authoritative with what is necessarily right. Most autograph is likely to contain slips and errors that are wrong by any absolute standard and would be acknowledged as wrong by the author if

they were pointed out to him. On the other hand, lacking such specific acknowledgment, a critic has no option but to view autograph errors as authoritative, since no higher authority can be envisaged than the author; but this concept does not prevent their critical correction. Correspondingly, when autograph is not preserved, the form of the text that lies nearest in genetic relationship to the lost original becomes the paramount authority; and its errors must be esteemed as part of the only authority that can be recognized, even though the critic should quite naturally correct them. The act of correction applied to the most authoritative document that is preserved must always in a sense controvert authority. There is no harm in this principle once it is recognized that authority and correctness are not necessarily synonymous. Under these circumstances, correction, but never revision, can be made to a more authoritative from a less authoritative state of the text, or independently by an editor.

Before the invention of the typewriter no difficulty was experienced in demonstrating that a document was autograph, provided that a sufficient number of undoubted specimens of the author's handwriting were preserved for comparison. However, if writing were to be defined narrowly as handwriting, an author composing directly on the typewriter would produce no document that could be admitted as autograph. This situation is anomalous, for whether an author manipulates a stylus of some variety or taps marked keys (or, indeed, records his words electronically on magnetized tape), he has himself produced his original, and no human intermediary has entered until a person other than the writer makes a copy. Autograph, therefore, must be interpreted to include documents produced in the originator's own handwriting, typewriting, engraving or recorded voice—or any of the usual variations of these mechanical processes. The difficulty created in demonstrating actual production by the originator does not affect a case for autograph; indeed, the unevenness with which typewriter keys are struck may offer evidence to the scientific investigator as demonstrable as letter formations in script.

**Determination of Original Copy or Copies.**—For all practical purposes the designation of a text as transmitted defines it as a nonauthorial copy; its degree of distance from the autograph original does not come in question. However, "original" must be taken only as a general term, for a preserved autograph may not represent the originally composed document but a transcript by the author, either as part of an act of further composition (which could include revision) or else as an act of producing a fair copy of the original document. Under few circumstances may a critic assume that the act of revision is absent from the production of an authorial fair copy, although it would be stretching the term to imply major rewriting rather than relatively minor polishing during what is generally a mechanical process. However, until an author has a fair copy (either autograph or transmitted) which satisfies him, the act of composition scarcely can be concluded. Thus several originals of varying form and date may be preserved in autograph, and variant transmitted texts may contain true authorial revisions.

The slippery nature of an original document must be emphasized, for critical writing has vastly oversimplified the problem. For example, a standard definition asserts that the aim of the textual critic is the restoration of a text, as far as possible, to its original form, if by "original form" is understood "the form intended by the author." This ignores the fact that at different times or for different purposes an author may intend a composition to take various forms, each of which will necessarily have its original. Even final intention, supposing it could always be determined when more than revision for literary excellence is present, may be an insufficient criterion. If the version of a play as cut and rewritten during rehearsals is printed, the author will have approved it as printed in its acted form, but if he had had an option he might have preferred to print the initial, more literary form. Revisions may be undertaken for various motives that do not meet with universal approbation. Such authors as William Wordsworth and Walt Whitman may in later years so alter their earliest printed originals as to achieve forms of their poems that call for parallel-text editions rather than the rejection (as the authors in-

tended) of the earlier original in favour of the one that certainly represented their final intentions. All alterations are not necessarily connected with a desire for literary perfection; changes in political beliefs or a desire to moderate too frank autobiographical details may operate. Moreover, it does not necessarily follow that critics will always agree that an author's purely literary revisions are superior to his earlier version.

At any distance authorial intention is usually quite impossible to determine for the details of a text, and cannot be used as part of any scientific definition. If the literary and then the stage versions of an Elizabethan play are both preserved, as with John Fletcher and Philip Massinger's *Bloody Brother*, no later critic in the absence of collateral evidence can estimate the author's intention concerning his relative approval or disapproval of the two different texts. If this is so, it is clear that a critic would be greatly misguided to estimate intention or presumed original form if only one of the two variant forms had been preserved, and the original existence of the other was either not known or merely to be inferred, with no opportunity to reconstruct its forever lost details. Thus a critic must use the term "original" form always with a recognition that the word is loose in substance; and a definition of textual criticism must hedge on its characteristics.

For example, all that can be known, in any strictly authoritative sense, about a lost original must ultimately derive from extant transcripts. As a result, the original can have no recoverable characteristics not found in the preserved transcripts deriving from it. The technical original must be thought of only as the last version of the text produced before the transcription of the extant manuscripts or prints, and their ancestors, began. In a textual-critical sense, therefore, this original may not be, and often is not the author's original, but instead some transmitted copy of that other original which is forever out of reach. Any number of lost versions may have intervened between the textual original and the author's lost original. Thus it is quite false to believe that the critic's purpose in determining the ancestor of the earliest preserved forms of the text is "to recover the author's original." Moreover, it is false thinking if what is called the archetype in Lachmannian textual criticism (see LACHMANN, KARL KONRAD FRIEDRICH WILHELM) is confused with the author's lost original instead of being identified neutrally as the manuscript (or print), inferential or extant, and presumed to be single unless proved otherwise, from which all other extant and inferential copies are derived. In some cases this technical original may be the author's original; in most, however, it will be some intermediate transcript of an author's forever lost autograph.

The aim of the textual critic, then, may be defined (1) as the methodical establishment of a text in its purest and most correct form or forms as limited by the evidence of preserved documents; and (2) as the application of further techniques, including critical judgment, to clear a text insofar as possible of errors still present in the methodically established, or documentary form. The end of this second process is to approximate at least that substantive correctness that would have appeared in an authorial fair copy of a text as represented by preserved documents.

**Accidental v. Substantive Variations.**—In this definition, the "purest and most correct form or forms" of a text refers not only to an original and its possible revision or modification, but also to a distinction often made in printed texts; i.e., between (1) the significant, or "substantive" readings of a text, namely, those affecting the author's meaning or the essence of his expression; and (2) others—such as spelling, capitalization, punctuation, word division—affecting mainly its formal presentation, which may be regarded as the accidents and therefore as constituting the "accidentals" of a text. It may be that one form of a text preserves with considerable fidelity the accidentals of an author while at the same time containing substantive readings that he has seen fit to reject on a later occasion. The first edition of John Dryden's *Indian Emperor* (1667) is manifestly closer to his autograph than any other printed edition, since the slightly revised second edition (1668) was set from the first, and the considerably revised third edition (1670) was set from the second. However, this third edition, which on the whole contains the most authoritative range of

Dryden's substantive readings, is manifestly inferior to the first in the authority of the accidentals, since in this respect it is a mere copy of a copy of the first edition; and Dryden's general approval of the text of this play for its revised substantives marked in a copy of the second edition can under no circumstances be taken as applying also to the variable compositorial characteristics, which in many cases have altered the third-edition forms of the accidentals from their generally more authoritative versions in the first edition. (It is most unlikely that Dryden ever saw the 1670 accidentals before publication.) In such a case the duty of the textual critic is clear. He must establish the facts that lead to the assignment of the third edition as the last revised substantive form of this text; and then establish the facts as between the rival claims (of the first printed edition and a scribal manuscript of an earlier version of this particular text) to be the most authoritative form of the accidentals on the whole. An editor would then place the most authoritative form of the substantives within the framework of the most authoritative form of the accidentals.

Much confusion has been caused in critical writing by failure to observe the two stages of procedure in the establishment of a text as remarked in the definition finally offered: (1) the fixing from documentary evidence by logical methods of the most authoritative form or forms; and (2) the emendation of this initially established text to approximate as nearly as possible an inferential authorial fair copy, chiefly in respect to its substantives. (In a completely modernized form of any old text, as is customary with the classics, the substantives constitute the sole problem, of course.) This final action achieves on a superior level the establishment of a critically definitive text. At one time only the first operation was called "textual" criticism, the second being known as "higher" criticism; but this distinction lapsed following the recognition that the second stage of purification involves more than simple critical judgment and may include bibliographical, paleographical and linguistic, as well as historical considerations.

The second stage of establishing a text does not differ essentially between manuscripts and printed books. However, the methods of utilizing preserved documents to establish the first, or documentary stage of the text often differ so widely between manuscripts and prints as to call for separate consideration.

### THE GENEALOGY OF MANUSCRIPTS

The majority of manuscript texts requiring methodical textual criticism date from ancient or from medieval days before the invention of printing, although the custom of manuscript circulation may lead to problems even in such late Renaissance authors as John Donne.

**Types of Genetic Relationship.**—The analysis of the relationship of preserved forms of a text, as a whole, ends in the drawing up of a genealogical chart, such as the following, appropriate for a text wholly or chiefly preserved in manuscripts:

The genealogical tree always diverges in its lines of descent from a preserved or inferential original, the strict definition of which has been given above as that latest immediate ancestor,

preserved or inferential, to all the manuscripts highest on the family tree; *i.e.*, to the heads of all families. The process of transcription by which the various copies stemming ultimately from this single great ancestor are formed is characterized by variation. If we exclude authorial or editorial alterations, variant readings arise only from the transmission of documents. Such variation, in the words of Sir Walter Greg, is postulated as universal; that is, every act of transcription introduces some variants. Variation is either "spontaneous" or "determined." Spontaneous variation is unconscious variation; it may range from a mere slip of the pen to addition, omission or substitution of readings through misreading or lapse of memory. Determined variation is conscious, and hence usually an attempt at emendation (correct or not) of fancied or of real faults in the copy being transcribed. Spontaneous variation is the more frequent. Of the variants introduced into any transcript, some will persist through subsequent transcription, whereas others will undergo further change and thus illustrate the rule of universal variation. In this way features peculiar to any manuscript are transmitted to its descendants but not in an invariable form. (Variation, one must recognize, is a neutral word and applies only to a difference between two readings, without respect to the order of derivation or to correctness.) Variation in a descendant may lead farther and farther away from the original reading; on the other hand, a descendant in varying from its immediate ancestor may actually restore by independent correction the reading of a more remote ancestor.

Variants may be vertical (*i.e.*, within a direct genetic line of descent) as when H, transcribed from G (or more likely from some lost intermediary), varies from G; or variation may be horizontal, as when A differs from B, both being manuscripts transcribed independently from O or from one or more lost intermediaries. (A and B are "collaterals" in that neither is an ancestor nor a descendant of the other.) It is horizontal variation that gives rise among collaterals to "grouping," or the arrangement of the manuscripts into family and subfamily groups according to whether they agree or differ in respect to particular readings.

Unless there is "conflation" (one manuscript affecting the readings of another by contamination), each family group shares an exclusive common ancestor deriving ultimately from the first independent descendants of the inferred or preserved great common ancestor O. In the tree above, the family groups are separated into A and B and their respective descendants, except that L joins both families by conflation and passes on this mixed inheritance to its descendants. A subfamily is a family whose ancestor is derivable from a manuscript which is the ancestor of still other manuscripts. For example, K and P are in separate subfamilies deriving from their ancestors E and F, which are collaterals deriving from B. In reading a genealogical table of texts, no inference can be drawn that a manuscript shown as deriving directly from another manuscript was in fact copied from the exact manuscript shown on the tree as a parent. Between G and H or between B and F any number of now lost manuscripts very likely existed. Hence all variants in H from G, or in F from B need not have arisen in the act of copying the actual manuscripts of H and F, though for economy of assumption the textual critic must so take it. All that is shown by the table is that the line of descent from G to H and from B to F is a direct ancestor-descendant one, and that H has no other known ancestor than G, or F than B. In other words, no manuscripts deriving from any ancestor other than G were used in the transmission of the text from G to H, whatever the distance between them.

The case is quite different with L. Here the scribe (or a previous editor) had in his possession two exemplars of manuscripts, one in the direct line of descent from D, and the other similarly derived from J. These two manuscripts were conflated when in cases of variation between them the scribe chose readings now from one and then the other (or else merely copied a manuscript that had been editorially revised and annotated by selected readings from another). In this case conflation joined two manuscripts of different genetic, or family relationship, for neither D nor J shared any common ancestor except the ultimate ancestor O. On the other hand, lesser conflation took place in Q, but here the contamination

served only to unite the members K and P of two collateral subfamilies. In the first instance, readings may appear together in L that had been used as genetic distinctions to separate the A and B families; *i.e.*, readings in which A and B and their descendants varied from each other. In the second, though variants may be reunited, the conflation, except fortuitously, includes no variant not characteristic of the B family as opposed to the A family.

Inferential manuscripts may appear in any family tree, although the recent tendency of textual criticism is to excise them wherever possible, as by Archibald A. Hill's theory of simplicity. An inferential (or hypothetical) manuscript marks a point at which some line of descent branches; it is a manuscript that must be posited to explain similarities between two or more other manuscripts, extant or inferred, when study shows that these are in a collateral and not in an ancestor-descendant relationship. In the sample tree, according to one school of thought, if A did not exist it would need to be posited provided one could show that C did not derive from D, or D from C, or C and D independently from O.

The process of determining the relationship of the manuscripts consists of isolating the major different family groups and then inferring the genetic grouping of the individual texts within these large groups. The process starts with a collation, or comparison of all known texts and a systematic recording of their variants, usually confined to substantive differences. According to Dom Henri Quentin, three major kinds of variants will develop: (1) variants shown by a single manuscript; (2) variants shown simultaneously by a few manuscripts; and (3) variants shown simultaneously by numerous manuscripts. The first are useless and must be disregarded. The second are valuable in determining families and subfamilies, for if the same few manuscripts repeatedly give a common reading different from all other manuscripts, it may be assumed that these few are clearly related and form a family or subfamily of their own. One of the first tasks, therefore, is to delimit the families by means of such variants as are found repeatedly to be peculiar to certain constant groups of manuscripts. The families thus determined, the groupings within each may be filled in. The precise way in which a textual critic operates to determine the relationship of all forms of his text can scarcely be summarized, because of the complexity of the evidence and the differences in the weight given to various kinds of evidence. In general, the critic aims first at establishing the facts of genetic relationship and then at determining the direction of the relationship between ancestor and descendant.

**Distributional Evidence.**—What Hill calls "distributional" evidence is chiefly of service in determining the basic facts of relationship or nonrelationship. In distributional analysis the arrangement of differences in the texts is utilized as evidence without attention to the nature of the differences. This method rests on the postulate that unity in readings in manuscripts is more probably referable to unity in their source than to coincidence. The facts of variance are enough. If the point of difference is, for example, the appearance or nonappearance of a particular word, distributional study does not attempt to inquire whether the nonappearance is an omission, or the appearance is an addition. It merely divides the manuscripts into groups depending upon the appearance or nonappearance of this word.

Distributional evidence may be used to assign the nature of groupings by indicating whether the relationship is direct (as in the vertical ancestor-descendant line) or collateral. For example, direct relationship can be shown in the following illustration. Suppose manuscript L shares readings with all other manuscripts in its family and has no unique readings. Manuscript M shares readings only with L and has no shared readings with other manuscripts not shared with L, but it also has some unique readings. This state of affairs is not compatible with a supposition that L is copied from M, since (because of the unique variants in M) the greater number of times that L agrees with the other manuscripts than does M is unexplained. On the other hand, this state of affairs is compatible with the hypothesis that M was transcribed from L.

One apparent fallacy in this reasoning is usually not of consequence. The larger share of L than of M in readings with other manuscripts could be explained, in isolation, as derivation of L

from M if M were the earliest of all manuscripts and all derived from it as the common ancestor. However, a tree branches as it develops, not converges; and no rational genealogical chart can be reversed. Moreover, other evidence, which may be called genetic, provides a check on the direction of change.

The facts of the distribution of variant readings among manuscripts, therefore, may be utilized to show direct relationship, as above, or collateral relationship. For the latter, if in a group of more than two manuscripts having a common ancestor (like M, N and R), all manuscripts have unique readings, and all manuscripts shared readings in no constant arrangement, these facts are compatible only with independent derivation of the type known as radiation. On the other hand, if the relationship is always constant, so that the shared readings of M are always shared only with N or with R, the facts can be taken to be incompatible with radiation and hence derivation must be postulated.

**Genetic Evidence.**—Distributional evidence is frequently enough to settle a case, but it has its limitations when revision is present and especially (as exemplified in the texts of Donne or Robert Herrick) when copies are made from a poem in different stages of reworking. Hence the critic may call on a second order of evidence, which may be called genetic, or the comparison of individual differences with each other in the hope of discovering the direction of change. At its most scientific this inquiry still attempts to emulate distributional study by ignoring the critical considerations of meaning, at least in any strict sense of right and wrong. Instead, genetic study rests on the assumption that certain differences are more likely to have been produced by a given direction of change than by another. For example, if C omitted a passage present in both A and B, the direct sequence CBA, or ACB or any other scheme that set up C ahead of B would be disqualified, for where would A or B secure the passage if they were descended from C, no conflation from another source being proved?

Common errors of other sorts may also profitably be used but always with caution, for the process of correction reverses the direction of change toward error that would be expected from the process of copying. The critic attempts to separate reversible changes from variants that by their nature appear to be non-reversible. Moreover, Greg's postulate that spontaneous variation occurs oftener than directed variation would indicate that in a direct sequence the number of errors will ordinarily exceed the number of corrections, and hence that the most faulty will likely be the descendant, not the ancestor; but this line of argument is to be used with caution.

Similarly, the direction of change may sometimes be postulated by explaining one form as the result of a known type of mechanical error such as eyeskip or haplography. Unless distributional evidence indicates otherwise, an existent word is presumed to be earlier than a nonexistent word created by a familiar type of error. Even when two existent words comprise the variant, a known type of error may best explain the direction of change. Hill points to E. K. Rand's correction of Quentin in the following: *sub umbra culminis mei* (9 manuscripts); *sub umbraculum culminis mei* (2 manuscripts); *sub umbraculum tegminis mei* (5 manuscripts). Quentin had regarded *umbra culminis* as derived from *umbraculum tegminis* by the omission of *-um teg-*, whereas Rand properly derived *umbra culminis* from *umbraculum culminis* by omission of *-um cul-*. Rand's logic rests on true eyeskip fostered by the repetition of *cul-*, whereas Quentin's suggested omission cannot be correlated with such a type of known error.

Suggestive as genetic evidence may be, assumptions from individual readings may often prove to be untrustworthy; and hence the genetic method is usefully employed only when distributional evidence has been completely exhausted.

**Physical and Stylistic Evidence.**—Physical evidence is ordinarily of little use in dealing with classical or medieval manuscripts, since no correlation need exist between the date of inscription and the state of the text. It is of no pertinence to argue, for example, that because the paper of manuscript Y may be dated in 1640 and that of manuscript Z in 1240, the text of Z must represent an earlier state than that of Y; instead, Y might

well have been transcribed from a manuscript that was representative of a form of the text nearer to the common ancestor than the ancestor of Z. However, modern manuscripts (and especially autograph) may yield extraordinary results when external evidence is applied. The manuscripts behind the 1860 edition of Whitman's *Leaves of Grass* neatly divide into groups that can be dated 1857 and 1859 respectively on the basis of the paper and inks. A brilliant recovery of the order of Emily Dickinson's manuscripts resulted from a minute external study of the paper and the handwriting characteristics.

Finally, in this preliminary stage, which consists only of the establishment of one form of a genealogical chart rather than any other, purely literary study based on assumed stylistic respects, superior sense, freedom from mistakes of fact, etc., is almost completely untrustworthy and should not be employed until the preceding three ranges of evidence have been completely exhausted, individually and collectively.

**Determining the Most Authoritative Variant.**—Once a genealogical chart has been drawn up by the critic's most rigid use of methodical evidence, it is proper to consider the authority of variants in the texts in the light of the facts of derivation as shown by the tree. In the sample chart it is obvious that if O is preserved no other known manuscript can contain a reading that possesses any authority, although some may own readings that are more correct. The textual critic will have arrived at the only preserved manuscript that—as the single common ancestor—is nearest to a lost autograph. Further treatment of this manuscript can involve only emendation.

On the other hand, if O is only inferential, and A and B represent the ultimate heads of only two families, the critic's position is less happy. True, no preserved manuscript other than A and B can own authority; true, shared readings between A and B must be presumed to derive from inferential O, and therefore common readings possess the authority they would have if derived from a preserved O. (But notice that in either case O is not necessarily the real archetype or first original, but instead merely the one manuscript it is possible to infer as a common ancestor of A and B, even though through different lost intermediaries.) However, where A and B vary, only critical judgment can decide, on the evidence of each individual variant, which one is superior and therefore—by another assumption not always warranted—authorial.

The school of textual critics stemming from Karl Lachmann favoured the acceptance of one "best" manuscript and the rigid adherence to its readings in all possible circumstances as the only "scientific" attitude for an editor. This school tacitly considered that textual criticism ended with the establishment of the family tree and the consequent decision in favour of some one preserved manuscript as the "best"; whereas, at least in the above chart, the tree does not favour either A or B. The illogic of the Lachmann position, in its abrogation of the critical second stage in preparing a definitive text, was exploded by A. E. Housman (Preface, *The Astronomicon of Manilius*, Cambridge University Press): "To believe that wherever a best MS. gives possible readings it gives true readings, and that only where it gives impossible readings does it give false readings, is to believe that an incompetent editor is the darling of Providence. . . . Chance and the common course of nature will not bring it to pass that the readings of a MS. are right wherever they are possible and impossible wherever they are wrong: that needs divine intervention. . . . In books like Manilius and Lucan, preserved in various copies of equal merit, the editor cloaks his frailty by feigning that their merit is not equal: in books like Juvenal and Ovid's *Heroides*, where one MS. far excels the rest, he feigns that it excels them further, and tries hard to treat it not merely as the best but as the sole authority."

Heeding Housman's exhortation, the most advanced textual critic no longer stops short with what the evidence of the genealogical chart may indicate about the authority of the readings; nor, when the chart is indifferent, does he rest content with fidelity to a chosen best manuscript. In every case of nonautograph he will accept only as comparative the authority of the earliest ancestors that can be established; and as the final stage of his establishment

of a text he will treat it critically according to bibliographical, paleographical, linguistic or whatever other techniques are pertinent, and over all impose his literary judgment based on his knowledge of the qualities of the author treated. At this point, where methodical techniques largely desert a textual-critic editor, the resulting text will be good or bad depending upon the individual's own capacities. The acceptance of Housman's attitude and its extension, about the middle of the 20th century, to editing from printed texts constitutes one of the most interesting of modern developments in editorial theory. It places the responsibility for a text where it belongs, squarely on the shoulders of the editor. Yet confidence in critical ability to solve all problems may lead to a newer kind of laziness as acute as that Housman found in the "scientific" textual critic, if all the ancillary techniques for examining a text are not exhausted before reliance is placed on judgment rooted in subjectivity and intuition and in the cultural intelligence of an editor.

### THE GENEALOGY OF PRINTED BOOKS

Transmission of a text in printed books differs so radically from transmission of an ancient or medieval manuscript text as to call for quite different basic postulates. The chief difference is that a manuscript that is a direct descendant of its most immediate ancestor is ordinarily not copied directly from the ancestor but from some one of a lost series descending from the ancestor. On the other hand, any edition of a book other than the first is ordinarily copied directly from some other known edition. Editions of books, therefore, are assumed to be contiguous in their relationship, and variants between them can be assigned to the agents producing the derived edition, or else to the author, within a given space and time. Secondly, under most circumstances editions of books are dated with reasonably correct dates, which show the relationship between editions. Both assumptions, although sometimes violated, permit the development of physical evidence that is the special province of analytical bibliography, a discipline that studies the effects of the printing process on the transmission of text (see BIBLIOGRAPHY).

For example, the ninth edition (1694) of Dryden's *Indian Emperour* appears to conflate distinctive readings of the seventh edition of 1686 and the eighth of 1692. In manuscript study or in nonbibliographical criticism of printed texts, an editor would inevitably postulate either consultation and contamination or else derivation from a lost edition located between the seventh and eighth. However, the bibliographer trained to observe physical evidence will notice that the distinctive variants of the two editions never appear together on any page of the 1694 print; and starting with this fact he will develop other physical evidence to demonstrate that two different compositors alternated in setting the type for the 1694 edition, one of whom used the 1686 and the other the 1692 edition as printer's copy.

**Determining the True First Edition.**—One of the most difficult problems facing a textual critic of printed books is to determine which is the true first edition, and thus the authoritative text, in case two editions in the same year are issued without external or collateral evidence of priority. Dryden's play *The Wild Gallant* had two editions printed in 1669, the year of publication. On literary grounds Dryden's editor G. Saintsbury rejected what turned out to be the true first edition, and chose for his text the variant readings of the unauthoritative second edition. When the case was scrupulously examined, one piece of physical evidence was enough to demonstrate the true order. In what was proved to be the first edition the word "tells" was printed with a defective type for the second letter "l"; the type inked chiefly at the top and in many copies produced only a short mark that looked like an apostrophe. In the second edition the compositor faithfully copied what he thought he saw and set the corresponding word as "tel's," an impossible form. That this evidence must be accepted may be seen if one tries to reverse it and explain the defective type as deriving from the apostrophe.

The chief textual critic of *Hamlet* between World Wars I and II, J. Dover Wilson, had pronounced the important second edition of 1604-05, the first of the good texts, as set throughout by only one

compositor, who was an incompetent novice at the trade. But in 1953-54 one bibliographer showed that, on physical evidence that could be demonstrated from the printing of the sheets of the book, two presses had been employed in an alternation that would require the services of two compositors. Another scholar, J. R. Brown, by an examination of distinctive characteristic spellings, identified the sheets set by each compositor as those indicated by the press-work study and established the fact that these two now identifiable compositors had worked for the printer for several years as his regular men and, indeed, had set the second edition of *Titus Andronicus* and the first edition of *The Merchant of Venice*, both in 1600. Since these two texts have been much admired for their accuracy, the effect of this inquiry was to establish that defects in the second edition of *Hamlet* are chiefly to be derived from its manuscript rather than from the printer's incompetency. The difference is important for a textual critic.

One of the most brilliant bibliographical discoveries of the 20th century disclosed the false dating of the so-called Pavier Quartos of various Shakespeare plays. It was established that Pavier editions of some plays dated 1619 and editions of others dated a decade or more earlier shared identical standing type in their title pages. This physical impossibility revealed that some texts previously preferred on literary grounds by editors, such as that of *King Lear*, were actually unauthoritative second editions of no textual value. Whether Hamlet's flesh was "too too sallied" (i.e., "sullied"), as in the First and Second Quarto editions or "too too solid," as in the Folio, had usually been decided in favour of the Folio. However in 1956 it was pointed out that the unusual form "sallied" in the second edition could not have derived unauthoritatively by contamination from the same reading in the imperfect first edition, since the second appearance in this play of the word "sally" meaning "sully" (Polonius to Reynaldo, Act II, sc. i) came in a section typeset by a different compositor, who would be unaware of the previous occurrence and must have copied his word from the manuscript, the first edition being wanting there. These examples suggest various typical ways in which bibliographical techniques that have been developed in the 20th century have revolutionized the study of printed texts by emphasizing the need to exhaust the physical evidence of analytical bibliography before attempting critical judgment.

The approach to textual criticism made by the analytical bibliographer emphasizes two primary requirements: (1) the careful examination of all preserved forms of a text, not only (a) to assure oneself that the external evidence of printed dates and the like is correct and that one has recovered the earliest edition (that text set from manuscript) but also (b) to guarantee that every other edition in which fresh authority might have entered has been placed in its correct relationship and the authority of its variants analyzed; (2) the careful examination of the details of any edition possessing authority, whether the first or a revised print, to determine the nature of the copy used by the printer and its authority.

**Determining the Nature of Printer's Copy.**—The usefulness of this inquiry is by no means limited to early handprinted books but may be applied as profitably to the texts of James Joyce, T. S. Eliot and W. B. Yeats as to the text of Shakespeare. The common practice of dilettante editors to reprint as their text the last edition of a book printed in the author's lifetime is as serious a defect for modern as for older authors. (The theory was that the author might have revised the edition; such editors felt no requirement to look into the evidence for or against this theory.)

To take a small but significant example, the proofreading of F. Scott Fitzgerald's *This Side of Paradise* was careless in the first printing, and changes in the plates were made partly by the author and partly by the publisher in the fourth and seventh impressions. A few of these alterations, presumably made by the publisher, mistook the sense and created errors from correct readings. An editor would need to reject these in favour of the correct first-printing readings, to accept the corrected and revised readings by the author and publisher from the later printings, and then to make a variety of further corrections himself before arriving at a definitive text. In more complex form, no one edition of Joyce's *Ulysses*

contains all of his desired readings; on the occasion when he went over the text in correction he unfortunately chose a corrupt edition and did not alter all its unauthoritative changes from the first-edition readings or notice all the first-edition errors that had been perpetuated. Any editor of Eliot or of Yeats would need to disentangle the author's corrections and alterations in revised editions from errors developed in the course of various printings, which were overlooked. Fidelity to one printing or edition, early or late, cannot serve to establish a modern author's text.

In the 17th century Dryden partly revised the second edition (1668) of *The Indian Emperour* and more rigorously the third edition (1670). The fourth and fifth editions of 1670 derived in order from the corrected third, but the sixth edition (1681) reverted to the second (1668); thereafter all texts of Dryden followed this family and ignored the corrected third edition, whose line terminated with the fifth edition. Since no Dryden editor before the 1950s undertook to collate all the early texts, the authoritative revisions of the third edition remained unknown, and the edited texts, based on the 1701 folio, not only retained most of the corruptions found in this 13th edition but also revealed only the intermediate revised state of the text as transmitted in the second-edition family line.

A typical example of failure to observe the primary rules of textual criticism in the analysis of all editions occurred in the text of Percy Bysshe Shelley's *Posthumous Poems*. In the first edition of 1824, edited by Shelley's wife Mary, an errata leaf containing 24 alterations, including a missing line, was added to the last copies to be bound up. This leaf, being uncommon, was overlooked by all Shelley's editors, although utilized to a greater or lesser extent in the various pirated editions that followed soon after the publication of the volume. When Mrs. Shelley came to edit the revised collected edition of 1839, by bad luck she chose one of the pirated texts into which various corruptions had entered. Thus, although she collated her proofs against her manuscripts, not only did she overlook three of the errata-leaf corrections omitted in the pirated edition but she also passed some of the piracy's corruptions, notably the reading from "Stanzas Written in Dejection, near Naples," "The breath of the moist air is light" for the errata-leaf version of this missing line, "The breath of the moist earth is light." The variant "air" appears first in the unauthorized Galignani text of 1834, to be transmitted thence to Mrs. Shelley's 1839 edition. All Shelley editors, who sheeplike followed the supposedly authoritative 1839 text in the belief that Mrs. Shelley's attestation had been given to it and hence there was no need to inquire into its copy and method of printing, have reproduced as authentic a considerable number of errors that can be demonstrated to have arisen in the pirated texts of Galignani and of Ascham used by Mrs. Shelley as the basic printer's copy.

The nearer machine printing approaches modern times and routine publishing procedures, the less need is there to inquire into the authority of the manuscript originally used as printer's copy, although the copy for any subsequent revised edition must always be identified and its relation to the earliest authoritative text as well as to the revised edition scrupulously analyzed. For books of the 16th, 17th and 18th centuries, however, when the personal characteristics of the compositor (though with diminishing force as time goes on) are likely to interfere in an important manner with the reproduction in faithful detail of the underlying manuscript, the distinction of printer's from author's characteristics is of real moment. Two considerations operate. First, in texts dating from the time when authors frequently did not read proof and the printing-house proofreading was casual about variation from the author's wording, a study of the printer may reveal whether difficulties in the text are to be emended in one direction or another in accord with what has been determined about the capabilities of the identified compositor concerned. It is known that Jagard's compositor A of the Shakespeare First Folio of 1623 was more faithful to his copy, generally speaking, than compositor B. Hence an emendation must pass sterner tests to be accepted in an A section of the Folio than in a B section, or in the pages set by what seems to be a very inaccurate apprentice, compositor E, first identified by C. J. K. Hinman in 1956.

Second, if the veil of print can be pierced, the critic may be able to make various important assumptions about the authority of a text, in whole or in part, according as he can estimate the nature of the lost manuscript underlying the earliest print or any later revision. Once it could be determined that a particular scribe, Ralph Crane, transcribed the manuscript used by the Folio printer for *The Merry Wives of Windsor*, certain very puzzling characteristics of that text were no longer obscure. What texts of Shakespeare were set from his autograph papers, and what from scribal transcripts, is an inquiry that was scientifically tackled, from the strict bibliographical point of view, only after World War II.

The question of the copy underlying a print is often as acute in the case of a revision as in the original edition. For example, if the Folio text of *Hamlet* was set from an independent manuscript, common readings between the Second Quarto and the Folio are presumptively authorial, given the collateral theory that the Second Quarto was set from autograph papers. On the other hand, if, as has been argued, the Folio printer's copy was a Second Quarto that had been annotated by a scribe comparing it with the manuscript in the theatrical company's possession, a shared reading like "pious bonds" (assumed manuscript reading: "bands") for "pious bauds" ("bawds") could have perpetuated in the Folio an error of the Second Quarto, provided the scribe overlooked it. Hence the authority possessed by any Folio reading is much affected by what can be established about the nature of the printer's copy for the Folio text, a subject still in dispute.

Such a determination would not automatically settle in any given case whether the Folio or the Second Quarto variant reading was the authoritative one. But a critic who comes to the final stage in the establishment of a text—the synthesis of readings if there is more than one text possessing authority (as is frequent in manuscript and occasional in printed texts), followed in any case by independent emendation—is in a better position if he has thoroughly worked out the detailed history of the text as a guide and limitation to the exercise of his critical or literary judgment than if he relies almost exclusively on his sympathetic acquaintance with the characteristics of an author and his period.

(F. T. B.)

**THACKERAY, WILLIAM MAKEPEACE** (1811–1863), English novelist, the author of *Vanity Fair*, one of the world's great novels, was born at Calcutta, India, on July 18, 1811, the only son of Richmond Thackeray, a third-generation Anglo-Indian in the service of the East India Company. Richmond Thackeray died in 1815, and in the following year Thackeray was sent to England. From 1822 to 1828 he was at the Charterhouse School and from 1829 to 1830 at Trinity College, Cambridge, leaving without taking a degree. From 1831 to 1833 he studied law, without much enthusiasm, at the Middle Temple. When he reached the age of 21 he inherited from his father a sum of money providing an income of about £500 a year, but within four years had lost most of it, some in gambling and various speculations, the rest by the failure of the great India Agency houses. Being obliged to support himself, he settled in Paris about 1834 to study art seriously. While living there he married in 1836 Isabella

ING BY SAMUEL LAURENCE, 1848

Shawe, an Irish girl of 19. Subsequently, following the death of their second daughter (1839) and the birth of their third (May 1840), Mrs. Thackeray suffered a severe mental illness that left her incapacitated till death (1894). Thackeray, to quote Anthony Trollope, "became as it were a widower to the end of his days," responsible for the upbringing of his two surviving daughters. (The eldest, Anne Isabella, married in 1877 Richmond Ritchie of the India Office. She wrote several works of fiction and subsequently edited Thackeray's works and published some volumes and reminiscences. The younger daughter, Harriet Marian, married Leslie Stephen in 1867 and died in 1875.)

Meanwhile, the Thackerays had returned to London in 1837 and Thackeray had turned from painting to journalism; from about 1841 to about 1846 he was one of the most accomplished free-lance journalists of the period. He early became a regular contributor to *Fraser's Magazine*, in which appeared in 1841 *The History of Samuel Titmarsh and the Great Hoggarty Diamond*, a work filled with the wit, humour, satire, and pathos, which found a more ordered if not a fresher expression in his later works. The characters are full of life; the book is crammed with honest fun; and for pure pathos, the death of the child stands in the company of very few such scenes in English fiction; but *The Great Hoggarty Diamond* had to be cut short at the bidding of the editor.

In 1840 appeared *The Paris Sketch Book*, much of which had been written and published at an earlier date. In 1838 Thackeray had begun, in *Fraser's*, *The Yellowplush Papers*, with their strange touches of humour, satire, and tragedy and their fantastic spelling; and this was followed by *Catherine*, a strong story, founded closely on the career of a criminal named Catherine Hayes and intended to counteract the then growing practice of making ruffians and harlots prominent characters in fiction. There soon followed *Fitz-Boodle's Confessions and Professions*, and the *Shabby Genteel Story*, a work interrupted by Thackeray's domestic affliction and afterward republished as an introduction to *The Adventures of Philip*, which took up the course of the original story many years after the supposed date of its catastrophe. In 1843 also came out the *Irish Sketch Book*, and in 1844 the account of the journey *From Cornhill to Grand Cairo*, in which was included the excellent poem of "The White Squall." In 1844 there began in *Fraser's* the *Memoirs of Barry Lyndon, Esq.*, called in the magazine "The Luck of Barry Lyndon, a Romance of the Last Century." "Barry Lyndon" has, with a great difference in treatment, some resemblance to Tobias Smollett's *Ferdinand, Count Fathom*—the hero, that is to say, is or becomes an intolerable scoundrel who is magnificently unconscious of his own iniquity. The form and pressure of the time depicted are caught with striking verisimilitude, and in the boyish career of Barry Lyndon there are fine touches of a wild chivalry, simplicity, and generosity, which mingle naturally with those worse qualities that, under the influence of abominable training, afterward corrupt his whole mind and career. The man is so infatuated with and so blind to his own roguery, he has so much dash and daring, and is on occasions so infamously treated that it is not easy to look upon him as an entirely detestable villain until, toward the end of his course, he becomes wholly lost in brutish debauchery and cruelty.

Thackeray became a contributor to *Punch* within the first year of its existence. John Leech, who was one of the earliest contributors, had been at Charterhouse with Thackeray and the two men were friends through life. Thackeray made his first hit with *Jeames's Diary*, begun in November 1845, and may be said to have established his reputation by the famous *Book of Snobs* (published in *Punch* under the title "The Snobs of England, by One of Themselves," 1846-47). "Punch's Prize Novelists," another series which Thackeray contributed to the paper, contains some brilliant parodies of Edward Bulwer-Lytton, Lever, Disraeli, and others. Because of differences in political opinion, his connection with *Punch* ended in 1851. Minor but admirable works of the same period are *Legend of the Rhine* (a burlesque of Dumas's *Othon l'Archer*), in George Cruikshank's *Table Book*, edited by Gilbert A. Beckett Cox's *Diary* on which was founded a well-known Dutch comedy, *Janus Tulp*), and *The Fatal Boots*. Re-

becca and Rowena towers over every other burlesque of the age. Its taste, its wit, its pathos, its humour are unmatched; and it contains some fine songs of a particular sort.

In January 1847 was published, by Bradbury and Evans, the first of 19 monthly numbers of *Vanity Fair*, the work which placed Thackeray as a novelist of the first rank. It was completed in July 1848 (the last number being a double number, in which year it was also published as a book). The charge of cynicism Thackeray has himself met at the end of the eighth chapter, in a passage which is the best commentary on the author's attitude. He explained how he wished to describe men and women as they actually are, good, bad, and indifferent: "Occasionally to come down from the platform, and talk about them, if they are good and kindly, to love and shake them by the hand; if they are wicked and heartless, to abuse them in the strongest terms politeness admits of. Otherwise you might fancy it was I who was sneering at the practice of devotion, which Miss Sharp finds so ridiculous; that it was I who laughed good-humouredly at the railing old Silenus of a baronet—whereas the laughter comes from one who has no reverence except for prosperity, and no eye for anything beyond success. Such people there are living and flourishing in the world—Faithless, Hopeless, Charityless: let us have at them, dear friends, with might and main. Some there are, and very successful too, mere quacks and fools; and it was to combat and expose such as those, no doubt, that laughter was made."

Another accusation brought against the book was that the colours were laid on too thick, in the sense that the villains were too villainous, the good people too goody-goody. The best answer to that can be found by reading the work itself with care. Osborne is meant to be a poor enough creature, and one whose poorness of character is developed as he allows bad influences to tell upon his vanity and folly. The good in him comes out in the beautiful passage describing his farewell to Amelia on the eve of Waterloo, in which passage may be also found a sufficient answer to the statement that Amelia is insipid and uninteresting. So with the companion picture of Rawdon Crawley's farewell to Becky Sharp. Who that reads it can resist sympathy, in spite of Rawdon's vices and shady shifts for a living, with his simple bravery and devotion to his wife? As for Becky, there is certainly not much to be said in her defense. The reader learns that she thought she would have found it easy to be good if she had been rich, and also knows what happened when Rawdon surprised her alone with and snatched to Lord Steyne in the house in Mayfair. After a gross insult from Steyne, "Rawdon Crawley, springing out, seized him by the neck cloth, until Steyne, almost strangled, writhed and bent under his arm. 'You lie, you dog,' said Rawdon; 'you lie, you coward and villain!' And he struck the peer twice over the face with his open hand, and flung him bleeding to the ground. It was all over before Rebecca could interpose. She stood there trembling before him. She admired her husband, strong, brave, and victorious." This admiration is the capital touch in a scene as powerful as any Thackeray ever wrote. The supreme art in the treatment of the character of the brilliant adventuress that makes the reader feel her attractiveness, though he knows her evil qualities.

*Vanity Fair* was followed by *The History of Pendennis* (serialized 1848-50), *The History of Henry Esmond, Esq.* (1851), *The Newcomes* (1853-55). *Esmond* is undoubtedly one of the greatest of English historical novels, reproducing with accuracy the figures, manners, and phrases of a past time. In 1851 Thackeray had written *The English Humourists of the Eighteenth Century*, delivered as a series of lectures at Willis' Rooms in the same year, and redelivered in the United States in 1852 and 1853, afterward the series called *The Four Georges* (published 1854).

In 1855 was published that delightful burlesque, *The King of the Ring*. In 1857 Thackeray stood unsuccessfully as a parliamentary candidate for Oxford and in the same year appeared the first number of *The Virginians*, a sequel to *Esmond*. The next number came out in 1859, and in the same year Thackeray undertook the editorship of the *Cornhill Magazine*.

was a task which, as readers of his *Roundabout Papers* in the *Cushion* will remember, the kindness and sensibility of his disposition made irksome to him, and he resigned his editorship in April 1862, though he continued to write for the *Cushion* until he died. In the *Cornhill* appeared *Lovel the Widower*, previously written, with different names for some of the characters in dramatic form; *The Adventures of Philip* (1861–62) in the *Roundabout Papers*, some of his best essays; and the unhappily never finished, called *Denis Duval* (1864). The *Roundabout Papers* is one differing in form from the one called "The Notch on the Axe—a Story à la Mode," an excellent specimen of the author's genius for burlesque story-telling. *The Adventures of Philip*, in the nature of a sequel to *Henry Gesteel's Story*, contains scenes which rank with Thackeray's best work; there are fine sketches of journalistic, artistic, and diplomatic life, but Philip himself is impossible; the character is not drawn at all. *Denis Duval*, which reached only four numbers, promised to be a first-rate work in the *Esmond* manner. The novel died while it was in progress, on Dec. 24, 1863. He was buried in Kensal Green, and a bust by Marochetti was put up to him in Westminster Abbey.

The grace and the apparent spontaneity of Thackeray's verses are beyond question. Some of the more serious efforts, such as "The Chronicle of the Drum" (1841), are full of power and in accord with true poetic feeling. Both the half-humorous, half-pathetic ballads and the wholly extravagant ones must be classed with the best work of that kind; and the translations from Béranger are as good as verse translations can be, for Thackeray had the true poetic instinct.

**BIBLIOGRAPHY.**—Texts: The standard edition of Thackeray's *Works* is the Oxford Edition, by George Saintsbury, 17 vol. (1908). This is preceded by *Thackeray's Contributions to the "Morning Chronicle"* by G. N. Ray (1958), and by *The Letters and Private Papers of William Makepeace Thackeray*, ed. by Ray, 4 vol. (1945–46). There are editions of *Henry Esmond* (1950) and *The Rose and the Ring* by Ray, and of *Vanity Fair* by G. and K. Tillotson (1963). Biographies: Ray's two-volume biography (*Thackeray: the Uses of his Life 1811–1816* [1955] and *Thackeray, the Age of Wisdom 1817–1863* [1958]) is the standard comprehensive life. The best of the biographies written before the publication of *The Letters and Private Papers* are M. Elwin's *Thackeray: a Personality* (1932) and L. Stevenson's *The Sheman of Vanity Fair* (1947). Critical Studies: C. Whibley, *William Makepeace Thackeray* (1903); Saintsbury, *A Consideration of Thackeray* (1931); J. W. Dodds, *Thackeray: a Critical Portrait* (1941); G. Tillotson, *Thackeray the Novelist* (1954); G. Ray, *The Buried Life: a Study of the Relations of Thackeray's Fiction and his Personal History* (1952). Bibliography: There is no complete bibliography, though extensive critical materials have been assembled by "Lewis Melville" Benjamin in *William Makepeace Thackeray*, 2 vol. (1910) and H. S. Van Duzer in *A Thackeray Library* (1919).

**THADDAEUS, SAINT**, is listed among the apostles of Jesus Mark 3:13 and Matt. 10:3. In the Western Church he is identified with Judas (of James). The Greek Orthodox Church regards him as separate persons and celebrates the feast of Thaddaeus on July 21. See **JUDAS, SAINT**.

**THAILAND** (formerly **SIAM**) is an independent constitutional kingdom occupying an area of 198,455 sq. mi. in the centre of Southeast Asia. The country lies to the west, north, and east of the Gulf of Siam, an arm of the South China Sea. On the southeast it is bounded by Cambodia; on the east and north by Laos, on the west, north, and northwest by Burma; on the west by the Andaman Sea, a part of the Indian Ocean; and on the southern extremity by Malaysia. The country's greatest extent is approximately 1,024 mi. (1,648 km.) and its greatest width about 485 mi. (780 km.). At the Isthmus of Kra in southern Thailand it is only around 30 mi. (48 km.) wide.

## I. PHYSICAL GEOGRAPHY

**1. Topography.**—With its crest forming a water divide and the boundary between Thailand and Burma, the Tenasserim Range continues southward to form the backbone of peninsular Thailand and Malaysia. Most of that part of northern Thailand that lies between the Salween River on the west and the Mekong River on the east has an elevation of from 656 to 3,280 ft. (200 to 1,000 m.). Within this deeply dissected upland the major mountain ridge tops and major river valleys are aligned in a general north-south direction. Four large rivers, the Ping, Wang, Yom, and Nan, originate in this area. Flowing southward, they unite to form the Mae Nam Chao Phraya, the largest river system in Thailand. The watershed of this river is almost surrounded by a U-shaped rim of hills and mountains composed of the Tenasserim Range on the west, the dissected upland on the north, and the Petchabun Mountains on the east. The latter form the boundary between an alluvial plain built by the Mae Nam Chao Phraya River in a now-filled upper arm of the Gulf of Siam, and an uplifted and tilted plain drained by the Mun River, a tributary of the Mekong. This uplifted plain is called Northeast Thailand by the Thais and is erroneously called the Korat Plateau by many foreigners. Northeast Thailand is not a plateau but a gently undulating plain with an elevation of less than 656 ft. above sea level. It is drained by river valleys that are comparatively shallow (seldom, if anywhere, is there a local relief of 500 ft. between the upland surface and the adjacent river valleys). The hilly and mountainous land between the Gulf of Siam and Cambodia is part of the Cardamom Mountains. Between this hill region and the Dong Rek scarp, which forms the southern boundary of Northeast Thailand, is a narrow but important lowland which extends eastward from the Bangkok delta plain to the Tonle Sap (Great Lake) area in Cambodia. Through this Thailand-Cambodian corridor have marched the armies of these two countries as attacks were made on one or the other's capitals.

The alluvial soils deposited on the river deltas and floodplains are the most productive because the rivers provide water for irrigation. Fruits and vegetables are grown on colluvial and residual slope soils which have accumulated at the foot and on the lower slopes of the hills and mountains. Clay soils are preferred in Thailand because they are impervious and help hold the water in the diked fields. Sandy soils do not retain water and are highly leached.

**2. Climate.**—Located in continental Southeast Asia, Thailand lies in that portion of the world affected by the so-called tropical

FIG. 1.—MAJOR CITIES AND SURFACE FEATURES OF THAILAND

monsoon climate. Consequently, all of the country north of Chumphon province has a rainy season during the months from May through October when the prevailing winds are from the southwest, and a dry season from December through April when the prevailing winds blow from the northeast. Unfortunately, the staff-shaped pattern of hills and mountains which enclose the plains of Thailand, Laos, and Cambodia places most of Thailand on the leeward or rain-shadow side of the mountains regardless of the direction from which the prevailing winds blow. For example, from May through October the southwest winds blow onshore and drop more than 100 in. of rain into the paddy fields of the Irrawaddy River delta in Burma; however, during the same period only about 50 in. fall on the Thailand side of the mountains.

Chumphon and the other 13 provinces (*changwads*) of peninsular Thailand have a tropical rain-forest type of climate, with the rainfall being distributed throughout the year. The other 57 provinces of Thailand have a tropical savanna type of climate. In these provinces about 85% of the rain falls during the summer monsoon and the dry months are extremely dry. Twenty-three provinces during their four consecutive driest months receive less than two inches of rain. This lack of precipitation during the dry season helps to create serious water problems and is an important factor in limiting most settlement to the floodplains near the permanent streams.

Except infrequently in isolated mountain areas of northern Thailand, frost and snow do not occur. Temperatures are above 10° C (50° F) throughout the year on the plains, and crops can be grown in any month if moisture is available. Temperatures below 18° C (65° F) and over 38° C (100° F) are rare. The coolest temperatures occur in December and January. Temperatures are uncomfortable during the hot dry season of February through May, when strong, dry winds blow across nonpeninsular Thailand.

**3. Vegetation.**—Although three-fifths of Thailand is in public domain and classified as forest, most of the valuable trees have been removed. The chief categories of forest cover are the deciduous and the evergreen (including coniferous forests). The deciduous forests, which occupy more than two-thirds of the forest area, can be subdivided into two types: deciduous *Dipterocarpus* and mixed deciduous. This latter forest contains the teak stands, several other commercial trees, and bamboo.

**4. Animal Life.**—Most of the wild animals and birds occupy the forests and the river valleys, but their numbers are decreasing. Among the mammals are elephants, tigers, and various small primates, including lorises. Included among the many varieties of birds are martins, babblers, and drongos. Although fresh- and salt-water fish are abundant, the intermittent and erratic flow of the rivers limits the number of fresh-water fish. Some of the fish have the ability to bury themselves in the mud and live through the dry season.

## II. GEOGRAPHICAL REGIONS

On the basis of differences in topography, climate, vegetation, and man's use of the land, Thailand may be divided into six regions: (1) Northeast Thailand; (2) the Central Plain; (3) North Thailand; (4) Southeast Thailand; (5) South Thailand; and (6) West and Southwest Thailand.

**1. Northeast Thailand.**—With 64,076 sq.mi. (165,957 sq.km.) in 15 provinces, Northeast Thailand contains about 32% of the country's area and 37% of its people. Although the region receives 57 in. of rain per year, most of it is not well suited for rice production because the rainfall is erratic and the sandy soils do not retain the water that does fall. The best soils are in the valley floors, but the valleys are shallow and narrow, and the adjacent streams erratic in flow.

Although about one-third of the rice area harvested is in Northeast Thailand, because of the low yields the area produces only about one-fourth of the annual crop. Almost all of the people are engaged in agriculture, and the two largest cities of the region, Nakhornratchsima and Ubon (Ubonratch-Thani) have a population of 42,218 and 27,222, respectively.

**2. Central Plain.**—With 46,293 sq.mi. (119,899 sq.km.) in 27 provinces, the Central Plain contains 24% of the country's area and about 35% of its people. Bangkok, the nation's capital and by far its largest city with a metropolitan population of 1,703,346, is in this region. Although the region receives an average rainfall of only 50 in. and although good yields from long-maturing rice varieties need 72 in. of precipitation, the Central Plain is the rice basket of Thailand. This is possible because the rain is supplemented by irrigation water from the rivers which flow from North Thailand to the Bangkok delta plain. The dark heavy clay soil of the Bangkok delta plain is the best in Thailand. Nearly half of the nation's rice crop land is in this region and more than half of the rice produced in the country is grown there.

**3. North Thailand.**—With 43,496 sq.mi. (112,655 sq.km.) in nine provinces, North Thailand has 22% of the country's area and about 12% of the people. Although this region is about the same size and has about the same amount of rainfall as the Central Plain, it produces only one-fourth as much rice. Rice production in North Thailand is limited by the small amount of level land found on the valley floors. Most of the area is still covered with mixed deciduous forest, which is the source of most of the teak harvest. One of the greatest contributions this region makes to the economy of Thailand is to provide irrigation water for the Central Plain.

**4. Southeast Thailand.**—The smallest region, with only 6,583

sq.mi. (17,050 sq.km.), Southeast Thailand has only  $\frac{1}{38}$  of the country's area. This region is sometimes included as part of the Central Plain, but it is hilly and mountainous; it receives nearly twice as much rain as the Central Plain and is covered with a tropical rain forest.

**5. South Thailand.**—With 18,261 sq.mi. (47,296 sq.km.) in seven provinces, South Thailand has 9% of the country's area and about 10% of its people. In these seven provinces of peninsular Thailand, agriculture is the most important occupation and rubber is a leading product.

**6. West and Southwest Thailand.**—With 18,898 sq.mi. (48,946 sq.km.) in nine provinces, this area has about 10% of the country's area and less than 4% of the people. The mines and forests provide the greatest sources of wealth in these provinces. (T. F. B.)

### III. THE PEOPLE

A large majority of the population of Thailand are culturally Thai; i.e., identify themselves as Thai, speak one of the Thai dialects, and behave in the Thai manner. Cultural differences among the country's four main regions—the centre, south, north-east, and north—are but variations within a single basic culture.

The physical characteristics of the Thai are similar to those of the majority populations in most southeast Asian countries. They are moderate in stature and weight, round-headed, and flat-nosed. They have medium-light skin, little body hair, and straight black head hair. These general characteristics do not sharply distinguish them from such peoples as the Burmese or Vietnamese.

Thai families average about five members, usually limited to parents and children. Extended family arrangements and polygamy are no longer commonly practised. While there is some preference for matrilineal postmarital residence, young married couples are free to settle wherever they please. Outside the old elite there is no concern for ancestry, and family names, instituted by royal decree only in 1916, are little used. Upper-class marriages involve a colourful religious ceremony, and a small religious rite is often performed for others. There are no legal impediments to divorce. Child training among the Thai is gradual and permissive. Within the family there is near equality and minimum division of labour between the sexes. Sons and daughters have equal inheritance rights. The dead are usually cremated.

Buddhism is at the core of Thai culture. More than 93% of the Thai ethnic group were adherents of Buddhism in the 1960s, and the country boasts at least 20,000 Buddhist wats (temple-monastery complexes). The local wat is the hub of community life in every village. The order of Buddhist monks is a major social institution, and the yellow robe worn by its members carries high prestige. Ideally all males join the order in early adulthood, and in fact a majority become monks or novices at least for a short period. Monks are celibate, live exclusively from alms, and eat no solid food after midday. They provide opportunities to laymen for merit making, perhaps the chief manifestation of Buddhist doctrine. Every religiously sanctioned act, from feeding a monk to building a new wat, accumulates merit to assure moral ascendancy and comfortable life in subsequent reincarnations. The Buddhist proscription against killing is taken very seriously by the Thai.

Animistic and Brahmanic elements are closely interwoven with Buddhism in the religious life of the average Thai, though

he is little aware of the distinctions among these traditions. In times of personal crisis most Thai propitiate spirits by prayer and offerings. Brahmanic elements are dominant in such rites of passage as the topknot-cutting and marriage ceremonies, not to mention the more elaborate ceremonies of state. The concept of heavens and hells, also incorporated in the popular religion, is Buddhist in origin.

Of the non-Thai groups, only the immigrant Indians and Pakistanis, the few westerners and the small remnant of Negritoid Semang in the southern peninsula have physical types readily distinguishable from the Thai. Southeastern Chinese, who form the largest minority, differ only slightly in physical type from the Thai majority. Prior to 1910 the grandchildren of Chinese immigrants were as a rule completely assimilated to the Thai population, but the assimilation rate subsequently declined with the rise of nationalism, of Chinese community schools, and of female Chinese immigration.

About seven-eighths of Thailand's Muslim population are Malays living near the southern border. Islam has provided an effective focus for Malay resistance to governmental attempts at forced assimilation. The small Vietnamese minority, consisting largely of postwar refugees, is still less assimilated, and many have been repatriated. Other culturally advanced ethnic groups in Thailand, including the Cambodians and Mons, are predominantly Theravada Buddhists and as such are more readily assimilated.

Thailand also has a rich variety of tribal groups, most of whom belong to three linguistic families: the Mon-Khmer (e.g., Kui, Kaleung, and So), the Thai (e.g., Lu and Putai), and the Tibeto-Burman (e.g., Aka, Lisu, and Musso). The last group of tribes, along with the Miao and Yao, are fairly recent arrivals in northern Thailand from southeast China. Karen tribes are also found in the mountainous country near the Burmese border.

Christians form only a tiny fraction of the total population (0.57% in 1960) and include a disproportionate number of Chinese, tribespeople, and other minorities. While Christian missionaries have had little success in converting ethnic Thais, they have been instrumental in introducing Western ideas and providing modern hospital and educational facilities. (X.)

### IV. HISTORY

**1. Migrations and Early Settlement.**—Peoples referred to by the Chinese in the 6th century B.C. as the barbarians south of the Yangtze-kiang are thought to have been the Thai (Tai). They and the Chinese bear striking similarities in both physical characteristics and language. As the Chinese extended their con-

tral southward the Thai must have gradually moved away in order to maintain their independence. These migrations took them centuries later into Upper Yunnan, the regions of the upper Mekong and upper Salween rivers, and the wide expanse of hill country covered by the Shan states of Burma. It was a gradual penetration by small groups, part of that almost imperceptible movement which characterized the peopling of the Indochinese Peninsula and the spread of its languages. It is still an open question whether the powerful kingdom of Nanchao, which emerged in the 7th century A.D. in Yunnan, was a Thai creation. Nanchao passed under Chinese suzerainty at the end of the 8th century. Its conquest in 1253 by Kublai Khan and his Mongols, it has been suggested, caused a mass emigration of Thai southward into the lands dominated by the Khmer Empire of Angkor, where ultimately in the middle of the 14th century they founded the kingdoms of Siam and Laos, dominating respectively the valleys of the Mae Nam Chao Phraya and upper Mekong rivers. Before 1253, however, a notable effervescence had begun among the Thai communities on the southern and western borders of Yunnan. Thai states also began to appear in the upper Mekong region and inside the Khmer Empire. In 1238 two Thai chiefs won control over Sukhothai, the capital of its northwestern region, and established what was to become, before the end of the century, the first important centre of Thai power and civilization within the area covered today by the kingdom of Thailand. In 1287, when the Burmese empire of Pagan fell before the Mongols, three powerful Thai rulers, Ramkhaeng of Sukhothai, Mangrai of Chiangrai, soon afterward to found the kingdom of Chiangmai, and Ngam Muang of Payao, concluded a pact of friendship. With Burma in eclipse, and Angkor losing control over its western territories, the time was ripe for a Thai bid for the dominance of both regions.

**2. Expansion: 13th to 15th Centuries.**—Ramkhaeng of Sukhothai expanded his power southward down the Mae Nam Chao Phraya and into the Malay Peninsula, over peoples who had been included in the Mon kingdom of Dvaravati before its conquest by Angkor in the 11th century. Their traditions had a profound effect upon Siam. Sukhothai under Ramkhaeng (1275-c. 1317) was the cradle of Siamese civilization, in which Mon-Khmer political, artistic, and literary traditions and Hinayana Buddhism of the Sinhalese pattern played a dominant role. In a political sense, however, the kingdom of Siam dates from the foundation of Ayutthaya in 1351, which in a very short time became the centre of one of the strongest states in mainland Southeast Asia, compelling the allegiance of the whole area comprising Thailand today, except the Chiangmai state in the far north, and in addition including the portion of modern Burma from Mandalay southward. On the east of Malacca, Siam's eastern limit, the 15th century gave birth to Ayutthaya from the merging of the entire Malay Peninsula. More or less continuous warfare for a long period of intensive struggle with Cambodia, which finally weakened the Khmer Empire, 1431. Cambodia might have been

added to the Ayutthaya kingdom had the Siamese not been at the same time in incessant, though unsuccessful, attempts to conquer Chiangmai, and in attempts, decisively defeated in the 1450s, to reduce Malacca. In the midst of all these wars, however, produced a notable administrator-king, Borom Trailok (1448-88), whose regulation of the land system and reorganization of the central civil and military administration not only upon the social life of the country until the great changes of Chulalongkorn's reign during the last quarter of the 19th century.

**3. Burmese Conquest and Recovery.**—When Albuquerque, after Portugal's conquest of Malacca in 1511, sent a Portuguese embassy to Ayutthaya, Siam was the most important state in Southeast Asia. Shortly afterward, however, the domination of Burma under the Toungoo dynasty, and the threat of the Burmese to dominate all the neighboring kingdoms. Chiangmai was conquered, all the Shan states now forming part of the Union of Burma became tributary, the Lan kingdom of Lan Chang (later Luang Prabang) was overrun, and Siam itself was subjugated in 1564 and again in 1569, and for 15 years was held by the Burmese. Siam was saved from this predicament by a great national leader, Phra Naresuan, and a difficult struggle, made all the more difficult by Cambodian raids, he set his country free and in 1590 succeeded to the throne as King Naresuan. Three years later he turned the tables on Cambodia by capturing its capital, Lovek, and making it a Thai state.

**4. Foreign Contacts.**—In the 17th century Siam developed overseas trade considerably. Both Pattani and Ayutthaya had important commercial connections with China and Japan, and in the century the Dutch and the English opened factories in both places. Siamese missions went to Japan and The Netherlands.

(LEFT) WATER PAVILION AT BANG PA IN, ONCE A SUMMER RESIDENCE OF THAI KINGS ON THE MAE NAM CHAO PHRAYA RIVER NORTH OF BANGKOK; (ABOVE) FLOATING MARKET ON A CANAL IN BANGKOK; (LEFT) MONK AND VISITORS IN A BUDDHIST TEMPLE AT SUKHO THAI; (BOTTOM RIGHT) PALM TREES AND RICE FIELDS IN THAILAND'S CENTRAL PLAIN

established so strong a position at Ayutthaya that the French king, Louis XIV, wrote King Narai in 1686 to the French for help. The encouragement he gave French missionaries, the Marquis d'Almeida, and the Dutch East India Company, the *Miscellaneous* (1686), and the opening up of the country to the monopoly of Siamese overseas trade. King Narai's interest in Siam was aroused by the French who suggested that King Narai might be converted to Christianity. Matters came to a head when the Greek Constantine became a dominant figure in the Siamese government. There were exchanges of diplomatic missions between Ayutthaya and France, and in 1687 a plan was set in motion for the conversion of Siam by Jesuits supported by French warships. The arrival of a powerful French squadron late in 1687 caused so much alarm in Siam that when in March 1688 King Narai became mortally ill, Phra Petraj, leader of an antiforeign party, executed Phaulkon, seized the throne, and forced the French to leave the country. The situation was complicated by a war which arose between the English East India Company and Siam over acts of piracy committed in the Bay of Bengal by ships built at Mergui, flying the Siamese flag, and employed by Englishmen in Phaulkon's employment. The arrival of two English frigates in June 1687 with orders from the British government to leave the Siamese service led to a conflict with the Siamese of all the English on shore. These events led Siam for many years to adopt a rigid attitude of hostility towards Europeans.

**Conflict with Vietnam and Burma.**—In the 18th century an expanding Vietnam was competing with Siam for the states of the upper Mekong and was also challenging the overlordship of Cambodia. But the gravest danger came from the new Konbaung dynasty of Burma, which revived the old subjugating Siam and in 1767 destroyed Ayutthaya and the country to chaos. Siam was saved by Chinese intervention and by the brilliant leadership of the half-Burmese general Phaya Tak, who reunited the country and made a new capital at Thonburi (Dhomburi) just across the river from Bangkok. In driving the Burmese out he reasserted authority over the Laos states and annexed Chiangmai. He regained control over Cambodia for Siam, taking advantage of the paralysis of Vietnam resulting from the dynastic conflict between the Tay Son brothers and the Nguyen of Hue. King Tak became insane and was deposed by General Chulalongkorn who made Bangkok the national capital and as Rama I (1809) became the founder of the present reigning dynasty. His country with success against another long series of invasions and raids, but his main efforts were directed towards internal consolidation. Before he died Siam had become a powerful state once more. It was during this period that Siam first took over from Cambodia the provinces of Battambang and Siem Reap that were later to prove such a bone of contention.

**Renewed Relations with the West.**—Rama II's reign (1824-51) was notable for the reopening of relations with the West. As the Burmese threat receded, Siam began to revive its claims to supremacy over the Malay states of the peninsula, and in 1824 the Sultan of Kelantan had ceded the island of Sumatra to Siam. In 1786 and a strip of the mainland opposite in 1800, Siam was concerned by Siam's deposition of the sultan in 1821 for trade, especially in foodstuffs and tin, with the southern states of Siam. When, however, John Crawford was appointed as the first British consul to the government of India, Siam refused to obtain any concessions.

The Anglo-Dutch Treaty of 1824 the Dutch withdrew from participation in the affairs of the Malay Peninsula. The Dutch were in possession of Penang, Malacca, and Singapore, and Siam was just in time to Siam's interference in the Malay Peninsula. The Dutch and Siam. This was the main object of the Anglo-Dutch Treaty of 1824. The Dutch's treaty with Rama III (1824-51) had the effect of stopping

further Siamese encroachments in western Malaya, but the cultivation of Siamese influence in the eastern states continued and advanced, especially in Kelantan and Terengganu. Siam's main expansionist policy, however, was directed towards Cambodia. Following a revolt in Vientiane, Siam in 1828 extinguished the kingdom and destroyed its capital. Less successful in an armed struggle with Vietnam for the possession of Cambodia, Rama III had to agree in 1833 to a treaty which gave Cambodia a nominal joint protection of both powers. Rama III was the last of the traditionalist monarchs who strove to obstruct all Western influence. His half-brother, Mongkut, who succeeded him as Rama IV (1851-68), abandoned the policy of isolation. His treaty of friendship and commerce with Britain in 1855, followed by similar treaties with the United States and most of the European states, opened the country to Western commerce and the establishment of foreign consuls exercising extraterritorial jurisdiction. He also began the process of modernization by his successive attempts to employ European advisers to reorganize the government services. During his reign Siam's influence over the Malay states suffered serious setbacks. The government of the British Straits Settlements effectively stopped the extension of Siamese control over the eastern Malay states of Terengganu and Kelantan and paved the way for the later establishment of British dominion over Malaya.

**7. Conflict with France.**—A more ominous development was France's conquest of Cochinchina, which began in 1859, its establishment of a protectorate over Cambodia, and subsequent exploration of the middle and upper Mekong. Siam had to surrender its claims to Cambodia, though by the treaty of 1867 it obtained in exchange French recognition of Siamese rights to the old Cambodian provinces of Battambang and Siem Reap. Chulalongkorn, who succeeded his father as Rama V (1868-1910), greatly increased the pace of Siam's modernization; his measures affected every department of the national life. During his reign French expansion in Indochina assumed threatening dimensions. The French conquest of Tongking, which caused Britain to annex upper Burma in 1886, led the Siamese to tighten their hold on the Laos country, which was being pillaged by refugee Chinese from Tongking. Under the influence of the explorer Auguste Pavie, however, France early in 1893, after various approaches to Britain regarding the boundaries of their respective empires in which both sides stressed their desire to declare Siam a buffer state, claimed that all the country on the east bank of the Mekong belonged to Vietnam. At the same time Pavie, who had become France's resident minister in Bangkok, demanded the evacuation of Siamese posts east of the river, and French columns took possession of the disputed territory, not without some resistance by the Siamese. France's hopes of provoking a conflict, which would enable it to seize the whole of the Mae Nam Chao Phraya, reached a climax in the "Tukong Incident" of June 1893, when two French gunboats entered that river and fired on Siamese boats at the entrance to the river, and forced the French to leave at Bangkok. For the next few weeks Siam's fate hung in the balance, with France insisting on its demands and Britain pressing France to moderate them and respect the independence of Siam, while at the same time urging Siam to save itself by accepting them. The crisis passed in the calm which followed when Chulalongkorn signed a treaty paying France a large indemnity, ceding the whole of the territory on the east bank of the Mekong, evacuating the provinces of Battambang and Siem Reap, and, as a guarantee, withdrawing Siam's forces to a distance of 16 mi (25 km) from the west bank of the Mekong and permitting the French to occupy the port of Chantaburi.

**8. Anglo-French Agreement.**—The incident brought Anglo-French relations to a crisis and in 1893 another treaty was signed between French claims in the upper Malay Peninsula and in 1894 two powers signed an agreement by which France renounced its claims to territory east of the Mekong in return for a mutual guarantee of the independence of the Mae Nam Chao Phraya Valley. France, however, continued to create further difficulties for Siam, until the signature of the Anglo-French entente cordiale in 1904 paved the way for a French settlement of outstanding questions. By a new treaty in that year Siam modified the Laos fron-

tier to France's advantage and renounced its sovereignty over Luang Prabang. France then evacuated Chanthaburi. By a further agreement with France in 1907 Siam ceded the Cambodian provinces of Battambang and Siem Reap in return for some of the territory surrendered in 1904 and the modification of some of the extraterritorial rights claimed by France. Finally in 1909, in return for a surrender of all its extraterritorial rights by Britain, Siam abandoned in favour of Britain all rights over the Malay states of Kelantan, Trengganu, Kedah, and Perlis. Siam also received a large sterling loan for railway construction.

**9. Reforms and Constitutional Changes.**—The Anglo-French agreement of 1896 encouraged Chulalongkorn to begin an accelerated program of reforms. Maha Vajiravudh (Rama VI), who succeeded his father in 1910, had been educated at Oxford University and had served in the British Army. He consciously imitated the methods by which Japan had made itself a great power capable of defeating Russia in 1905. He joined the Allies against Germany in 1917, thereby gaining millions of pounds worth of German shipping as war booty and membership in the League of Nations for Siam. His brother Prajadhipok (1893–1941), who ascended the throne in 1925, found the state finances seriously encumbered by his predecessor's extravagance. His measures of economy were unpopular, especially when as a result of the depression of 1930 the price of rice declined sharply. The political crisis which arose at the end of 1931 brought to the fore a brilliant young lawyer, Pridi Phanomyong, who with army help carried through a bloodless revolution in June 1932 and established a constitutional monarchy. By this constitution, which was promulgated in December 1932, a unicameral National Assembly of 156 members came into being, half appointed on the advice of the government and half by popular election. It was a legislative body with control over the budget and ministerial actions, and with the right to override the royal veto. Executive power was to be shared between the king and a state council comprising 15–25 members, two-fifths of whom were to be nominated by the king. Difficulties arose at once as a result of Pridi's ideas regarding the reform of the national economy and the growing rivalry between him and Pibul Songgram, the leader of a militarist and extreme nationalist group. There was also in 1933 an abortive royalist revolt led by Prince Bovaradej. Then in March 1935 the king abdicated over the question of the curtailment of his powers of veto, and his ten-year-old nephew, Ananda Mahidol, a schoolboy in Switzerland, was proclaimed king with a regency council of three members. Very soon a tendency toward military dictatorship began to manifest itself; the state council was paralyzed by quarrels and the assembly in December 1938 brought about its resignation. The new government, headed by Pibul with Pridi as minister of finance, plunged into a program of economic nationalism including measures designed to replace foreigners, especially the Chinese, by Siamese in industry and commerce. The official name for the country was changed in June 1939 to Thailand, "land of the free," education was brought under the strictest control, and the Siamese were required to wear Western dress and adopt Western manners.

**10. World War II and After.**—After the outbreak of World War II Japanese pressure upon French Indochina stimulated Thailand to revive its claims to those areas which had been taken by the French between 1893 and 1907, and from September 1940 to March 1941 the state became involved in spasmodic warfare on its eastern border. Through Japanese mediation the French ceded in May 1941 about 21,000 sq.mi. (54,390 sq.km.) to Thailand, namely that part of the protectorate of Laos which lay west of the Mekong River and three-fourths of the Cambodian province of Kampong Thom (the new frontier there running through Battambang and Siem Reap). Although not wholly satisfied with these Japanese-arranged terms and desirous above all of maintaining its independence, Thailand was swinging increasingly into the Japanese orbit and away from its traditional friendship with Great Britain. On Dec. 8, 1941, after five hours of fighting, Thailand agreed to permit Japanese troops passage through the country to invade British Malaya. This was followed by Japanese occupation of the country. (See WORLD WAR II.)

On Jan. 25, 1942, Thailand declared war on Great Britain and the United States. The United States did not declare war on Thailand. In Washington, D.C., the Thai ambassador, Seni Pramoj, organized a free Thai movement to counteract the Japanese. Through its offices about 90,000 guerrillas were organized in Thailand under the leadership of the regent Pridi Phanomyong. In July 1943 Japan transferred to Thailand territory including the four Malay states and two Shan states from Burma.

With the defeat of Japan the declaration of war of 1942 was declared null and void. In 1946 peace treaties between Thailand and Great Britain and between Thailand and France were signed on Jan. 1 and on Nov. 17; territories and properties acquired during the war were returned; and on Dec. 16 Thailand joined the United Nations. From 1950 Thailand participated in the Korean War in support of the United Nations. In September 1954 the nation became one of the members of the Southeast Asia Treaty Organization (SEATO).

Internal politics after the war were marked by another series of *coups d'état* and attempted coups, and by a number of changes in the constitution. The first postwar constitution (May 1946) established a bicameral legislature. Then, on June 9, 1946, King Ananda Mahidol was found shot dead in circumstances that gave rise to suspicion of murder. As his brother Bhumibol Adulyadej (1927– ) who succeeded him was a minor, a new regency had to be set up. Meanwhile the governments since the end of the war had been dominated by Pridi Phanomyong, but he was forced to flee from the country by the coup of November 1947. The power behind this coup was Marshal Pibul Songgram, who had been prime minister from December 1938 to July 1944. Under the provisional constitution of November 1947 the legislature remained bicameral, with 100 members in each house; but membership in the upper house was reserved to nominees of the crown. By a further coup in April 1948, Pibul Songgram again made himself prime minister. The constitution promulgated in March 1949 embodied most of the features of that of 1947. In the last days of November 1951, on the eve of the young king's return from Switzerland where he had been completing his education, the ruling group of politicians organized a new coup, whereby the constitution of 1932 was restored. The unicameral assembly was to comprise 123 elected and 123 nominated members, the latter alone sitting until elections would take place; the real point of the change seemed to be to reduce the royal power. In March 1952, however, a somewhat modified version of this constitution was promulgated. The nominated members were gradually to be replaced by elected members until in 1962 the whole assembly would be elected. In September 1957 Pibul was forced to flee the country following a *coup d'état* led by Marshal Srisdi Dhanarajata (Sarit Thanarat), the commander in chief of the army, who then became supreme commander of the armed forces but did not himself take the post of prime minister. On Jan. 28, 1959, an interim constitution was promulgated under which a constituent assembly of 240 members appointed by the king was set up to draft a permanent constitution and to act as a legislative national assembly. Marshal Srisdi Dhanarajata became prime minister. The government's primary aim was to overhaul and modernize the machinery of national administration, and it adhered to the Southeast Asia Treaty Organization. Notwithstanding those political upheavals at the summit, Thailand's social progress since World War II has been notable for internal peace and prosperity, a rapidly growing population, and considerable expansion in the field of education. Compulsory primary education is almost universal. Successful projects for agriculture and industrial development were also inaugurated. Dhanarajata died in December 1963, and his deputy prime minister, Gen. Thanom Kittikachorn, became prime minister.

During the early and mid-1960s Thailand, whose policy was strongly anti-Communist, was much preoccupied with the advance of Communist influence in Southeast Asia. Many Communists were arrested in Thailand itself. Cambodia, accused by Thailand of encouraging Communist subversion in the region, broke off diplomatic relations in 1961. In 1962 U.S., British, Australian, and New Zealand forces, acting under the provisions of the

SEATO Treaty, moved into northeast Thailand when, in the course of the civil war in Laos, pro-Communist Pathet Lao troops reached the Laos-Thailand border on the Mekong River. The SEATO forces were withdrawn after the Laotian settlement later in the year. In January 1965 a Chinese Communist-sponsored organization, the Thailand Patriotic Front, called for the overthrow of the regime in Thailand. There was a steady buildup of U.S. forces in 1966 and U.S. bombers in action over North Vietnam were based at fields in Thailand. Pres. Lyndon B. Johnson visited the country in October 1966. (D. G. E. H.; X.)

## V. POPULATION

Thailand is not densely populated. With a population of 26,257,916 in 1960, 132 persons per sq.mi., the land is not fully exploited. Population distribution is closely related to agricultural productivity. The highest densities and the most extensive concentrations of population are found in the flood plains of central Thailand. Secondary concentrations occur in the alluvial lands along the Chi and Mun rivers in northeast Thailand, several well-watered valleys in the north, and the plains along the gulf coast in the far south. Fully one-third of the total population lives in the northeastern region.

The population, approximately 7,300,000 in 1900, had by the time of the 1947 census increased to 17,442,689 and in the census of 1960 reached 26,257,916. According to the *United Nations' Demographic Yearbook, 1962*, 88% of the Thai people are rural and dwell in villages. Statistics are available for only 120 municipalities. In these cities live 3,273,865 people, about 12% of the population. Bangkok, with 1,299,528, accounted for 40% of the municipal total. If Thonburi (pop. 403,818) on the west bank of the Mae Nam Chao Phraya River is combined with Bangkok, the Bangkok metropolitan area had a total population of 1,703,370, or 52% of all the people living in municipalities.

In 1947 life expectancy at birth was 48.5 years for males and 51.4 years for females. Between 1947 and 1955 the crude death rate fell from 13.4 to 8.2 per thousand. During the same period the recorded birth rate rose from 23.6 to 30.0. Fertility is highest in the northeast and lowest in the north and the Malay areas of the far south. With the exception of foreign-born immigrants, among whom men predominate, the sex ratio is very nearly equal. The age distribution is fairly typical for nonindustrialized Asian countries; children under 15 account for more than 43% of the total population.

Only about 12% of the population falls outside the Thai ethnic group. Chinese, of whom there were approximately 3,000,000 in 1960, form by far the largest ethnic minority. Chinese immigration, 1918-31, showed a net surplus of 500,000 Chinese immigrants. Since 1948 immigration has been restricted to a negligible figure, and the total number of China-born Chinese in 1960 was 384,408. Ethnic Chinese are concentrated in Bangkok and the upper gulf region, the tin and rubber areas of south Thailand, and the major up-country towns. The only other sizable immigrant minority is the Indian-Pakistani group, numbering about 70,000 in 1958 and, like the Chinese, predominantly urban. Ethnic Malays, the second largest minority (about 600,000 in 1958), are concentrated in the four southernmost provinces. The population also includes incompletely assimilated Cambodians, Vietnamese, Mons, and Shans, totaling approximately 300,000, and a comparable number of tribespeople.

## VI. ADMINISTRATION AND SOCIAL CONDITIONS

Before 1932 Thailand had an absolute monarchy. Then a bloodless revolution replaced it with a nominally constitutional semiparliamentary monarchy. In practice, Thailand is a unitary state with a highly centralized and bureaucratic government, controlled and operated by an oligarchy or a military dictatorship. Thailand's constitution, which was adopted in principle, has not yet been completely implemented in action. For example, the constitution provides for a legislative body, the assembly of peoples' representatives, one-half of whose members during a transition period were to be elected by the people and the other half to be nominated by the king and approved by the cabinet. Al-

though more than 30 years have passed, the people have never been given the opportunity to elect all the members of their own assembly; moreover, the assembly at times has not been permitted to function. Beginning in 1956 national acts were passed from time to time with the objective of helping to decentralize the national government and strengthen the autonomy and development of local governments. However, local activities were severely restricted by the limited power of the local government to raise money by taxation. Consequently, many people took little interest in either local or national governments.

**1. Government.**—By statute the administration of the country is divided into three parts: (1) the central administration; (2) the provincial administration; and (3) the local administration. The central administration consists of ministries and departments located in the capital, Bangkok. The country is divided into provinces called *changwads*, each of which is under the control of a governor. These governors represent the provincial administration, which in reality is not a separate independent branch of the government but performs the territorial line service for the central administration. The latter performs the staff service for the provincial administration in the capital. The governors are not elected by the people but appointed by the national ministry of the interior, to which they are responsible. Governors are not permitted to remain in a *changwad* for many years and can be ordered from one to another or dismissed. But during his tenure in a *changwad* the governor is all-powerful because he is "in control of all the provincial officials in his province and is responsible for the governmental service of the province and the districts."

Each of the provinces is subdivided into districts called *amphurs*. There is a district officer for each of the districts. These officers are not elected but are appointed by the governor. The Local Administrative Act of the Buddhist Era 2457 (1914) lists in detail the powers and duties of district officers in 50 articles covering more than ten pages. Duties are grouped under the following six categories: (1) general administration of the territory; (2) maintenance of public safety and public peace; (3) magisterial functions: functions as chief magistrate in criminal inquiries and judicial powers in civil cases involving a claim not exceeding 200 baht (approximately \$10); (4) administration of public health and sanitation; (5) stimulating economic development; and (6) education.

A district is further subdivided into communes called *tambons*. According to the *Tambon Government Administrative Act* (1956), the ministry of interior can authorize local government for a *tambon*. However, local autonomy has been granted to only about 60 of these communes.

In summary, the Thai government is run by executive order. The executive branch of the government dominates at all levels by making and administering policy, holding the legislature in virtual subservience, and wielding some influence on the judiciary. The council of ministers, which is the executive body theoretically appointed by the king but in reality selected by the self-appointed prime minister, is composed of from 14 to 24 ministers; it is theoretically responsible to the assembly for the general policy of the government. During a coup, however, a strong man can (1) make himself prime minister; (2) inform the king whom he wishes to have as ministers; and (3) ignore the assembly.

**The Monarchy.**—According to the constitution the king is head of state. Theoretically, all governmental powers are administered in his name, but he has few assigned concrete powers. Every act of state in which he participates must be countersigned by an appointed minister. The king is primarily a symbol of the nation's unity. Standing above the strife of politics, he symbolizes the country's ideals and aspirations. The king represents the state at major public ceremonies and sets the standard of style and deportment.

**Legislature.**—In 1932 parliamentary institutions were established by the leaders of the coup. A unicameral assembly of the people's representatives was organized. However, many of the early assemblymen had little understanding of their duties. In spite of this handicap, between 1933 and 1939 the assembly often

showed real independence. After 1947, when the military returned to power in another coup, the cabinet generally bypassed the assembly or used it to rubber-stamp cabinet proposals.

The assembly of 1957 had 283 members of whom 160 were elected and 123 were appointed by the cabinet. Whether elected or appointed, the members received the same pay and had equal powers. After the coup by Field Marshal Srisdi Dhanarajata in 1957, the assembly was dissolved. An interim assembly of 240 members was appointed by the king in 1959. Both General Srisdi and the king promised the people free elections and the establishment of constitutional parliamentary government. After General Srisdi's death in 1963 Gen. Thanom Kittikachorn headed the government.

(T. F. B.)

**2. Justice.**—A ministry of justice was instituted in 1892. Thereafter the old tribunals, in which customary law had often been corruptly administered, were replaced by organized courts with judges appointed from the Bangkok law school and under the direct control of the ministry (except in the most outlying parts). A provincial judicial scheme provided a court at the headquarters of each *changwat* and also a series of central courts. A supreme court was established at Bangkok. In 1915 a bar association was formed.

Meanwhile the independence of the courts was still compromised by international treaties under which extraterritorial rights were secured to foreigners until the national law should be fully codified. After the absolute monarchy had delayed for years over the work of codification, the constitutional regime rushed it to completion, enabling Siam to denounce the international treaties in 1936 and to be freed from extraterritoriality within 14 months. Further legislation by the constitutional government was designed to reform procedure, to introduce the Western type of will, to strengthen the status of the judiciary, and to extend the course in the law school to three years. The spread of crime, stimulated by the political changes, provoked a reorganization of provincial justice. The *gendarmierie* courts were replaced by district courts and police authority was strengthened. Prison reform was begun, penal colonies were established, and reformatories for juvenile delinquents constructed.

Thailand is divided into four divisions for judicial purposes, though certain courts in Bangkok are excluded. There is a court of appeal and a final court of appeal to deal with points of law. Civil cases and serious criminal cases have to be heard by at least two judges. There is no jury system.

**3. Defense.**—Something of the part played by the armed forces in Siamese politics is indicated in the paragraphs on history above. Conspiracies in 1912 and in 1917 foreshadowed the struggle between civil and military elements that dominated the early constitutional period and culminated in the army's supremacy from 1938, save for the interval 1944–47. Symptomatic of this military influence was the Yuvajon movement, started in 1935, for the military training of schoolboys. A law of 1937 made all males between the ages of 18 and 30 liable for military service.

The navy, which had been officered wholly by Siamese since 1906, had its strength doubled in the first decade of the constitutional regime, when modern warships were bought from Italy and Japan. The traditions of the national air force go back to 1912, when Rama VI sent some of his subjects to France for training as pilots and mechanics and to World War I, when Siamese aviators were sent to the Western front.

(X.)

## VII. THE ECONOMY

The nature of Thailand's economy varies among the geographical regions, each having somewhat different natural resources and economic development. All of the regions cultivate rice and have fishing resources, fish providing the major protein element in the national diet. The northern region is the source of most forestry products, while the central region around Bangkok is the nation's financial, commercial, and industrial centre. The southern peninsula produces most of the rubber and tin. The northeast has few resources.

**1. Agriculture.**—Rice is the principal base for the country's economic well-being. In the 1960s more than 76% of all culti-

FIG. 2.—PRINCIPAL LAND-USE REGIONS OF THAILAND

vated land was planted in rice. Before World War II Thailand exported about 1,500,000 metric tons of milled rice annually. Exports declined during the war but by 1961 the prewar total was again achieved. The long-staple, nonglutinous quality of Thai rice makes it highly competitive in world markets. After the war the rice industry was placed under government control. This control was modified in 1955, and since then rice has been exported mainly through private channels. At the same time, the government set a fluctuating export premium on rice aimed to keep it competitive.

The sowing and planting season for rice is from June to August and the reaping season from December to February. About 50 varieties of paddy are grown. Seed selection aimed to improve the quality of the Thai rice is a continuous enterprise. Water variation and its control are also of continuing concern. Sheet-flooding of the Bangkok plain, in order to be adequate, must maintain a level at Ayutthaya, north of Bangkok, 11.5 ft. higher than the sea in the bight 35 mi. away. The plain is covered with a complex of channels to spread rather than to control the flood. East of the Mae Nam Chao Phraya River water controls and irrigation canals have been constructed in grid patterns, with an

irrigation barrage across the river itself at Chainat. Off-season cropping and rotation are not usual in the commercial farming areas.

About 1,000,000 ac. in southern Thailand are planted in rubber on small estates owned by Thai and ethnic Chinese. Annual pre-war production was generally less than 50,000 metric tons, but by the middle 1960s it had risen to about 200,000 metric tons. The industry cannot expand to any great extent without a substantial replanting program, but implementation of the Rubber Replanting Act of 1960 is handicapped by competition from synthetic rubber production.

Cotton is planted on about 130,000 ac. of poor soil in the north-eastern and northern part of the central plain and is afflicted by insect pests. Annual production of seed cotton amounts to about 40,000 metric tons of short-staple cotton. Tobacco is cultivated chiefly in the cotton area and includes three types: flue-cured, sun-dried leaf, and a Turkish type for blending. Sugarcane production rose steadily from 105,000 ac. cultivated in 1948 to more than 400,000 ac. in the mid-1960s. Almost all sugar is consumed locally. Corn is of rising export importance, with Japan the principal consumer. Other products include tapioca, peanuts, soybeans, coconuts, sesame, castor beans, silk, and pepper.

**2. Forestry.**—About 125,000 sq.mi. of Thailand are covered with forest, of which about 35,000 sq.mi. in the north contain teak. Teak production rose after World War II to approximately 200,000 cu.m. in the middle 1950s but by the 1960s had declined to less than 150,000 cu.m., of which about 50,000 were exported annually. The industry was chiefly developed by British companies. In 1954 the government began not renewing forest leases on expiration and in 1959 announced its intention to nationalize the industry. The Forest Industry Organization, a government body, supervises teak concessions, the teak being exploited by the Joint Timber Co., Ltd., which is a grouping of the leading teak concession holders.

The lac industry is chiefly of domestic importance although its high quality has gained the confidence of foreign buyers. Other forestry products include yang oil, bamboo, rattan, charcoal, gums, and resins.

**3. Livestock and Fisheries.**—Cattle and buffaloes are the principal livestock, cattle usually numbering about 5,000,000 and water buffalo about 7,000,000. Some sections of the northeast are suitable for grazing, and cattle and hogs are raised for shipment, mostly to other parts of Thailand. Dairy cattle are almost nonexistent. Horses are used chiefly in the northwest and number about 200,000.

Thailand's rivers and 1,500 miles of coastal waters abound in fish of great variety. Commercial fresh-water fish production for domestic consumption varies between 50,000–70,000 metric tons annually. The salt-water catch averages about 150,000 metric tons, most of which is consumed domestically. Since the introduction of cold-storage facilities, shrimp production has gained importance. The fishing fleet consists of more than 4,500 boats with a total gross weight of over 33,000 tons.

**4. Mining.**—Mining, except for tin, is not of major importance. Tin mines are located chiefly in the southern peninsula and are generally operated by British, Australian, and Chinese companies. Many of the dredges deteriorated during the war but by the 1950s prewar production levels of about 15,000 metric tons annually were regained. Tungsten is found in association with tin. In the years shortly after 1950 annual shipments of tungsten ore varied from 1,000 to 1,600 metric tons, but this total had declined by the 1960s. Iron deposits are estimated at about 70,000,000 tons of low-grade ore, located in remote regions. Production of steel and pig iron amounts to about 45,000 metric tons each per year. Lignite deposits are estimated at about 15,000,000 tons. Salt is processed from seawater and in bulk is an important export item.

**5. Industry.**—Thai industry is limited to the processing of agricultural commodities and the fabrication of consumer products and building materials. No branch of industry, except the processing of some agricultural products, has achieved sufficient volume to satisfy domestic requirements. There are rubber fac-

ories, sawmills, tobacco-processing plants, sugar mills, yarn mills, weaving factories, cement plants, glass factories, and factories for plywood and steel. Large-scale ventures depend on foreign capital, chiefly in the form of bank loans. Private foreign investors are scarce. A Thai National Economic Development Board was established in 1959 to promote industrial development. The board assigned high priority to transportation, power generation, and communications. The International Bank for Reconstruction and Development provided Thailand with loans for economic development. Part of these funds financed the foreign exchange requirements of the first phase of the Bhumiphol (Yankee) Dam, located in the northwest, which is expected to aid economic development by providing irrigation and hydroelectric power. In addition the Development Loan Fund and the Export-Import Bank of Washington made loans to Thai industry.

**6. Trade and Finance.**—In general Thailand exports raw materials and imports finished products. Rice is the most important export item, generally accounting for between 30% and 45% of the total exports. Major rice customers include Malaysia, Indonesia, and Hong Kong. Malaysia imports much of Thailand's rubber and tin concentrates for processing and reexport.

In the 1960s the bulk of Thailand's imports were supplied by Japan, the United States, and the United Kingdom in that order. Traditionally Thailand's exports exceeded imports, but in the 1950s and early 1960s the balance was generally adverse.

The Thai currency unit, the baht, consisting of 100 satangs, is considered hard currency at about 21 to the U.S. \$1. In 1955 the multiple-rate currency structure was displaced by a free exchange rate. In the mid-1960s Thailand's gold and silver reserves were approximately \$550,000,000. Government budget revenue is generally exceeded slightly by expenditures.

**7. Communications.**—Waterways (about 3,700 mi. of rivers and canals) carry more than half of Thailand's freight. The main arteries are formed by the Mae Nam Chao Phraya River and its tributaries. Intercommunication is accomplished through three important canal systems: the Pasak South system east of the Mae Nam Chao Phraya, the Phuphan system north of Bangkok, and the Western system.

The waterways are supplemented by a state railway system begun in 1892 which has more than 2,000 mi. of meter-gauge lines. This system radiates from Bangkok to Malaysia in the south, to Cambodia in the southeast, to Ubon in the east, to Udonthani in the northeast, and to Chiangmai in the north. The Japanese built a junction line to Burma during the war, but it has been dismantled. Railway earnings from operations, together with loans from the International Bank, generally provide adequate funds for maintenance and modernization of the lines and rolling stock.

In the mid-1960s there were approximately 6,500 mi. of highway. Stretches of well-built road exist, but they often must be reached over narrow dirt roads. Most roads serve mainly as interconnections between the rail- and waterways. The Northeast Highway (100 mi. of which is asphalt) connects Bangkok with Nongkhai at the Laos border, and a southeast highway connects Bangkok with Aranyaprathet at the Cambodian border. An east-west highway was opened in 1961 connecting Phitsnulok with Lomsak.

Domestic airline service is maintained by the government's Thai Airways Co., Ltd., with airports at most provincial centres. Thai Airways merged with a Scandinavian airline to provide international service for Southeast Asia and started operations in April 1960. Bangkok is an important centre for worldwide commercial aviation, with more than 20 airlines operating through the city in the 1960s. The airport is capable of handling jet passenger planes. Reconstruction of local airfields, completed in 1960 at Chiangmai, Nakhornratchasima, Taklee, Udonthani, and Ubon, provides facilities for handling most aircraft.

Thailand joined the Universal Postal Union in 1885. Internal communication is handled through the post and telegraph department. The mail service uses railroads and airplanes to cover the country. Telegraph service reaches only principal commercial and railway centres. Radiotelegraphy is used largely for government messages, the government owning and operating the radio

network. There are two television stations, one operated by the ministry of defense and the other by a semigovernmental corporation. Telephones are few. Bangkok is reached internationally by surface and air mail, radiotelegraph, and radiotelephone.

**THAI LANGUAGE.** Thai, the standard spoken and literary language used throughout Thailand, is specifically the dialect of Bangkok and its environs. Slightly different local dialects are the Northeastern (around Ubon), the Northern (Chiangmai), and the Southern (Nakhonsrithamrat).

**Structure.**—Words are predominantly monosyllabic, but many are polysyllabic. There are 21 consonant sounds: unaspirated *p, t, c, k, ʔ* (*c*, palatal stop; *ʔ*, glottal stop); aspirated *ph, th, ch, kh*; voiced *b, d* (plus *g* in final position only); spirants *f, s, h*; semivowels *w, j* (Eng. *y*); nasals *m, n, ŋ* (*ng*); liquids *l, r* (often confused). Nine vowel qualities are distinguished: front *i, e, ε* (*æ*); central *y* (*i*), *ə, a*; back rounded *u, o, ɔ*. These also occur long (*ii, ee, ee, etc.*) and in three clusters *ia, ya, ua*. Of equal significance are the five tones, mid (unmarked), low (*ˊ*), falling (*ˋ*), high (*ˊˊ*), and rising (*ˊˋ*) used to distinguish lexical meanings: e.g., *khao* "stuck," *khao* "a curry spice," *khao* "kill," *khao* "trade," *khao* "leg." (For explanation of these symbols, see PHONETICS.)

Inflection is completely lacking, but derivation is vigorous. Reduplication, often with vowel alternation, provides words like *krasibkrasab* "whisper." Compounding is highly productive; e.g., *khamnam* "preface" (word-leading), *khawcaj* "understand" (enter-heart). Synonym compounds like *haanklaj* "far distant" and alliterative compounds like *ramadrawan* "cautious" add greatly to the beauty and expressiveness of the language.

Word order is quite rigid. The typical sentence contains subject, verb, object in that order: *khaw<sup>1</sup> rian<sup>2</sup> khandtasad<sup>3</sup>* "He<sup>1</sup> studies<sup>2</sup> mathematics<sup>3</sup>." In attributive constructions the "head" precedes: *phaa<sup>1</sup> baan<sup>2</sup>* "thin<sup>2</sup> cloth<sup>1</sup>." In counting nouns a classifier is added to the construction in the order noun numeral + classifier; e.g., *miid saam-lēm* "three knives" (knives three-pieces). Verbs are primary or secondary, the latter being translated as adverbs. Thus *naam<sup>1</sup> lon<sup>2</sup>* "the water<sup>1</sup> recedes<sup>2</sup>" ("recede," primary) but *nan<sup>1</sup> lon<sup>2</sup>* "sit<sup>1</sup> down<sup>2</sup>" ("down," secondary).

**Loanwords.**—Thai freely incorporates foreign words. Perhaps the oldest are Chinese (*si* "four" and other numerals), but recent Chinese loans also occur. Hundreds of elegant and literary words are taken from Pali and Sanskrit (*prathēd* "country," *pradeśa*), and new words are coined from Sanskrit roots (*thoora-sab* "telephone," *dura* "far" + *fabda* "sound"; cf. the Greek-derived term in English). There are loans from Khmer (*truad* "inspect," *truac*), from 16th-century Portuguese (*sabun* "soap"), from French (*méd* "meter"), from Malayo-Polynesian (*tuu in* *pratuu* "door"), and in modern times increasingly often from English (*waaw* "valve," *maj* "mile").

**Writing.**—The Thai alphabet (instituted A.D. 1233) derives ultimately from the Devanagari of South India. Writing proceeds from left to right, and spaces indicate punctuation but not word division. The accompanying table shows the 42 consonant signs

### Thai Alphabet

CONSONANTS						VOWELS AND SPECIAL COMBINATIONS					
SIGN	EQUIVALENT	TONAL CLASS	SIGN	EQUIVALENT	TONAL CLASS	SIGN	EQUIVALENT	SIGN	EQUIVALENT	SIGN	EQUIVALENT
ก	k	middle	ข	th	low	เ	a	เ	a	เ	a

### TONAL MARKERS

- (1) — (NO MARK): MIDDLE TONE WITH MIDDLE CONSONANT; RISING TONE WITH HIGH CONSONANT; MIDDLE TONE WITH LOW CONSONANT.
- (2) ˊ: LOW TONE WITH MIDDLE CONSONANT; LOW TONE WITH HIGH CONSONANT; FALLING TONE WITH LOW CONSONANT.
- (3) ˋ: FALLING TONE WITH MIDDLE CONSONANT; FALLING TONE WITH HIGH CONSONANT; HIGH TONE WITH LOW CONSONANT.
- (4) ˊˊ: HIGH TONE WITH MIDDLE CONSONANT; RARE OTHERWISE HIGH TONE.
- (5) ˊˋ: RISING TONE WITH MIDDLE CONSONANT; RARE OTHERWISE.

still in use (two others are now obsolete), the tonal markers, and the vowel system. Although the 42 consonant signs are used for only 21 sounds, they are divided into three tonally restricted classes, middle, high, and low, as explained in the chart. Much of the seeming duplication is tonally significant; the rest preserves the etymological spelling of Indic and Khmer loanwords.

**Affiliations.**—Other closely related Thai or Tai languages are spoken in Laos and in parts of Vietnam, southern China, the Shan states, and Assam. Differences are chiefly phonetic and lexical. The languages also differ in the number of tonal distinctions; some have five, some six, some seven, but seven is the maximum so far discovered. Attempts have been made to connect the Tai languages with other language families such as Chinese, Malayo-Polynesian, or both, but a rigorous demonstration of such affiliations has not yet been provided. See also SOUTHEAST ASIAN LANGUAGES; TAI LANGUAGES.

H.)

**THAI LITERATURE.** Siamese writing is thought to have originated from the type standardized by King Ramkhaeng of Sukhothai in 1283. This type, modified by his grandson King Lülai about the middle of the 14th century, resembles the Lanna script.

Literature of the Sukhothai period (13th–14th centuries) survives only in inscriptions and in the *Traibhumikatha* of King Lülai in 1345. This, like the inscriptions, is dated and is almost modern in its citing of authorities, and, unusually, states the name of its author. The famous stone inscription of Ramkhaeng is valuable for its information about the king and its lively picture of contemporary life. The voluminous religious literature of the north, dating from the 15th and 16th centuries, includes the *Jinakāṇāṇī* (1516), a history of Buddhism and its spread to Ceylon, Pagan and the Lanna country in Pali verse; the *Cāmadevīyons*, a history of the state of Lampun in Pali verse; and the *Sihinganiḍāna*, a history of the Ceylon image of the Buddha and its wanderings in Siam. Folklore is represented by the popular *Paññāsajātaka*, a collection of 50 tales in Pali prose and verse.

In 1349 Ayutthaya succeeded Sukhothai as capital. The literature surviving the sack of Ayutthaya in 1767 may be divided into two periods. Of the first, from 1350 to about the 15th century, *The Oath of Allegiance* is the earliest and contains old and obsolete forms of words; the *Yuan Pai* ("Defeat of the Yuan"; i.e., Chiangmai people) is philologically valuable for its high literary standard; the *Royal Version of the Mahajati*, an ethical poem exalting the value of charity, influenced popular taste; and *Pra Lo* is a tragic romance. Prose survived in law preambles, some of them dignified and elegant.

Of the golden age of the later Ayutthaya period, from the reign of King Narai in the 17th century to that of "His Majesty of the Sublime Urn" (1732–58), several works, mostly poetry, have survived, including among Buddhist works King Sondharm's poem for recitation, the *Mahajati*. The *Samudaghos*, adapted from one of the folklore tales of the *Paññāsajātaka* by the king's preceptor, is a model of Siamese rhetoric. The king's preceptor was also credited with writing *Cindāmani*, a standard Siamese grammar in verse, and *The History of Ayudhya*, discovered early in the 20th century by Luan Prasroeth and known as *The History of Ayudhya*, version of *Luang Prasroeth*. Another poet of Narai's court was Pra Sri Mahosoth, famous for his *Panegyric of King Narai*. To Sri Prajna was ascribed the *Wailings of Sri Prājna*. Prince Kung or Dharmadhibes, whose *He rūa* ("Song of the Boatmen") has perpetuated his name, also wrote beautiful poems describing pilgrimages to the Buddha's footprint at Saraburi, and *nirās* ("erotic poems"). The *Bumvād* by Pra Māhānāg is famous for its descriptive eloquence. There were also dance-dramas, such as the *Dalang* and *Inao*, both inspired by the Panji romance of Java, which became classics of Siamese literature. Prose stories appeared, including the *Duodecagon* (Sibsongliem) from the Persian and the *Story of Nang Tantrai* (adapted from the *Arabian Nights*). *Pakaramam* ("moralist") prose literature was derived from Hindu sources.

Chaos in literature followed the sack of Ayutthaya's capital by the Burmese. The king's death and the dissolution of the court resulted in the loss of many literary treasures. This, and the absence of printing, contributed to the paucity of Ayutthyan literature.

After the restoration the king tried to revive the country's culture. His successor caused a complete examination and concordance of the canon of the *Tipitaka* (1788) to be made and a new corpus of laws known as the *Edition of the Three Seals* (1805); he commissioned translations of Pali and foreign classics, among which was the *Sāmkok* translated by Caophya Praklang (Hon) from the Chinese historical romance *Sankuo* ("The Three Kingdoms"). Under his patronage were written many histories of the Buddhist religion in Siam. One of the greatest works was the *Rāmākien*, written by the king and finished in 1798. It is the earliest complete Siamese version of the story of Rama, though it was probably modeled on a version lost in the sack of Ayutthaya, and because of this cruder source lacks the high moral tone and

the philosophy of Vālmiki's *Rāmāyana* from India. Traces of this epic can be detected in Siamese art and literature. It assumed a decorative role in monastic architecture though forming no part of the Buddhist religion.

Rama II, a gifted poet and dramatist, wrote the famous version of *Inao* as well as episodes of the *Rāmākien* and popular dance-dramas such as *Sankhtong*. His private secretary, Suntorn Bhu, wrote the fantasy of *Pra Abhaimani* and numerous *nirās*, for which he is famous. He also shared in the writing of the popular romance of *Khun Chang Khun Phen*. In 1835 Rama III built a stone library of inscriptions in which he collected most literary and technical knowledge, excluding poetical classics such as the *Rāmākien* and *Inao* and others, and thus summarized traditional Siamese literature up to the introduction of western influence in 1850.

Under Prince, later King, Mongkut, a new era of liberal thought in literature began. Prose fiction developed rapidly. The court still led in culture and adapted themselves to the new order while maintaining what was best in the old traditions. Mongkut's successor, King Chulalongkorn, began the publication of books dedicated to the dead which replaced the traditional burial presents, thus stimulating literature.

King Rama VI introduced the western spoken drama and Shakespearean blank verse, and adapted several plays by Shakespeare, Sheridan, Molière and Pinero, as well as composing traditional dance-dramas. Prince Bidyalongkorn wrote the well-known *Sāmkruṅg* in verse. Among the best-known poetry of the Bangkok period is *Ilaraj* by Phya Sri Suntorn (Phan), *Samagghibhed* ("The Disruption of Unity") by Jit Buradat and the *Nidrajagrij* by King Chulalongkorn.

The best novels include *Kamanit* by Sathienkoses and Nagapradip, several by Dokmaisod and *Siphendin* ("Four Regions") and *Phaiden* ("The Red Bamboo") by Kukridhdi. Outstanding in contemporary religious literature is the Pali *Sangitiyavangs*, a history of Buddhist synods by Somdeč Pra Vanarat, and a poem *Talengpai* by Prince Paramanujit, later Patriarch, notable for its rhetoric. He has been considered one of the greatest modern Siamese poets.

**THAI PEOPLES.** Thai (or T'ai) is a generic term applied to various groups of people found primarily in mainland south-east Asia who exhibit linguistic and other cultural similarities. The distribution of the Thai extends from Assam to Hainan Island and from latitude 25° N. in the Chinese province of Yunnan to the Gulf of Siam. The heaviest concentration is in Yunnan, Burma, Laos and Thailand (q.v.).

The major groups are the Siamese (in central and southern Thailand), the Lao (in Laos and northern Thailand), the Shan (in northwest Burma), the Lu (primarily in Yunnan but also in Burma, Laos, northern Thailand and Vietnam), the Yunnan Tai (the major Thai group in Yunnan) and the Tribal Tai (in northern Vietnam).

Population figures are difficult to substantiate. Several estimates conservatively place the total number of Thai in the 1960s at 33,000,000–36,000,000, including 22,000,000–24,000,000 in Thailand (both Siamese and Lao), 1,250,000–1,500,000 in Laos, 1,250,000–1,500,000 in Burma, 8,000,000 in Yunnan (including 750,000 Lu), and about 700,000 in Vietnam.

The Thai languages are tonal and monosyllabic. Thai grammar shows definite affinities to some Chinese languages and some linguists assign the Thai languages to a Sino-Thai language family. The many words of Sanskrit and Pali origin found in Siamese, Lao and Shan can be traced to superimposed Buddhist and Hindu influences (see **THAI LANGUAGE**; **THAI LITERATURE**).

Most Thai are Buddhists of the Theravāda (or Hinayana) school (see **BUDDHISM: Schools of Buddhism**). However, among the

different groups there are considerable variations in this type of Buddhism. In the villages of many Thai groups the wat (temple compound or monastery) serves as the social as well as the religious centre. The ideal is for all young men to spend at least a nominal period of time as monks before taking their lay positions in the village. Along with the Buddhist tradition there exist pre-Buddhist animistic beliefs; shrines are dedicated to spirits (*phi*) that are important in day-to-day affairs. These animistic beliefs tend to be strongest among those peoples who are farthest from the traditional centres of Thai Buddhism.

Rice cultivation is the major economic pursuit of all Thai. Some tribal groups raise dry rice in the highlands, but most Thai live in the valleys where they raise wet rice.

Thai social organization is based upon a small, independent bilateral family—households usually consisting of a husband, wife (or sometimes wives) and unmarried children. The status of women is high; none of the Thai peoples has a caste system, although formerly war captives and debtors could be held as slaves.

Though the Thai live in political entities varying from independent kingdoms to chiefdoms in non-Thai states, the basic structure of their semiautonomous villages is similar. An elected village headman (together with the Buddhist monks and elders) provides the leadership for communal projects.

The Thai appeared historically in the first century A.D. in the Yangtze valley. Chinese pressures forced them south until they were disseminated throughout the northern part of southeast Asia. By the 7th century they were found in the kingdom of Nanchao in Yunnan and by the 13th and 14th centuries Thai kingdoms existed in Assam, Burma, Laos and Thailand. However, Indian and Chinese influences permeated some Thai cultures, bringing about the Indianization of the Ahom (*q.v.*) in Assam and the Sinicization of some of the Thai in Yunnan and Hainan. Cultural identity has remained the strongest among the Shan, the Siamese and the Lao.

Although subject to Asian and European influences that have resulted in the assimilation of many new ideas, the Siamese have maintained cultural and political independence (except for brief periods under the Burmese) since the 13th century. Nevertheless, the powerful social and technological forces brought to the Thai by Chinese, Indians and Europeans have led to cultural diversity among the Thai peoples in different geographical areas as well as between the peasants and elite within such contemporary countries as Thailand and Laos.

**THAIS**, Athenian courtesan of the late 4th century B.C., traveled into Persia with the army of Alexander III (*q.v.*) the Great and is chiefly known from the story that represents her as having persuaded him to set fire to the city of Persepolis in the course of a drunken revel. The authenticity of this anecdote, which forms the subject of Dryden's *Alexander's Feast*, is doubtful, since it is based upon the authority of Cleitarchus, one of the least trustworthy of the historians of Alexander, and Alexander probably had political reasons for his act. Thais may have gone to Persia as the mistress of Ptolemy, later king of Egypt, whose wife or concubine she became.

Courtesans were often called Thais (hence the name could be used for an effeminate man); Menander wrote a comedy with this title, and the courtesan named Thais in Terence's *Eumuchus* provided Cicero, and after him Dante, with a notorious example of flattery. There is also a Christian saint Thais, a prostitute converted by Paphnutius or some other monk from the Egyptian desert, but her story is probably fictitious; it was used by Anatole France for his *Thais* (1890) and thence for J. Massenet's opera of the same name (1894).

**THAL**, the name given to the central section of the Sind Sagar *doab* or tract of country in West Pakistan, lying between the Indus River and its tributary, the Jhelum-Chenab. Because the land

is slightly more raised above the water level of the rivers than in the other *doabs* of the Punjab, it remained for a long time without benefit of canal irrigation. With a very low rainfall it was a sea of sand and silt, with an occasional village relying on a little precarious cultivation in one of the damper hollows or on goats' finding a little fodder in the thin grass cover that sprang up after a better than usual rain. Although there has long been irrigation of the lower ground along the margins of the Indus, there was no site on the Indus where a barrage could readily be constructed at a sufficient height to command the Thal Desert, and there was some fear of taking too much water out of the river lest the great dam at Sukkur should suffer. However, with the independence of Pakistan the great Jinnah Barrage was undertaken, and it was expected that the Thal would eventually be able to support 1,000,000 settlers. (L. D. S.)

**THALAMUS**, an ovoid mass of nerve cells and fibres in the middle of the brain, has the function of relaying all sensory impulses except those of smell on their way to the cerebral cortex. The organ is about 4 cm. (1½ in.) long and is divided into a number of nuclei, or nerve-cell groups.

In submammalian vertebrate animals the thalamus is chiefly olfactory and does not relay specific sensation, for there is no somatic cortex. With the development of the cortex in the mammals, and the projection of the sensations upon it, the sensory relay nuclei of the thalamus expand proportionately. Thus, the thalamus shows a large nucleus, the lateral geniculate body, behind and laterally for relay of visual impulses; a round medial geniculate body adjacent for hearing; and a large somesthetic nucleus in its lower central part for bodily sensations. These three are the fundamental and best understood of its nuclei.

The thalamus may be divided into about 30 nuclei, each with differing connections and, therefore, differing functions. Most of them project to one or another of the numerous areal units of the cerebral cortex, so their function is indicated by that of the corresponding cortical area, where this is known. A few do not; they are the most ancient and conservative. Ignorance of the incoming connections of most of the nuclei is chiefly responsible for ignorance of their function. It is known, however, that the thalamus is not directly responsible for motor control.

The thalamus is rarely directly injured or the primary seat of disease, but it may be involved in more generalized disturbances. See also BRAIN; HYPOTHALAMUS. (W. J. S. K.)

**THALES**, one of the Seven Wise Men of ancient Greek philosophy who was also universally held to have introduced geometry into Greece, was the son of the Carian Examyas of Miletus and of Cleobuline. The story of his Phoenician descent is unlikely. His date is fixed by the statement of Herodotus that he foretold an eclipse now generally agreed to be that of May 28, 585 B.C. Apollodorus' date for his birth, 624 B.C., was doubtless based on this as a *floruit*. According to Diogenes Laërtius he died in the 58th Olympiad (548–545 B.C.), aged 78.

His inclusion in the canon of the Seven Wise Men gave him an ideal character, and his name attracted many acts and sayings popularly associated with wisdom. Consequently his real achievement is hard to assess, especially since no contemporary sources exist. He was a practical statesman who, according to Herodotus, offered the wise advice that the Ionian cities should federate; and Diogenes states that he dissuaded Miletus from making an alliance with Croesus of Lydia. Practical interests are also indicated by the story told (but not believed) by Herodotus that he diverted the river Halys for Croesus, and by the tradition mentioned by Callimachus that he advised navigators to steer by the Little Bear rather than the Great. He is also said to have used his knowledge of geometry to measure the pyramids (Hieronymus of Rhodes cited by Diogenes) and to calculate the distance from shore of ships at sea (Eudemus cited by Proclus).

Such stories of little historical worth may yet serve to characterize his reputation. They could however be invented or selected according to a writer's predilections. Two in particular provide amusing examples of mutually canceling propaganda. According to Aristotle, Thales, foreseeing by his meteorological skill a glut of olives, hired all the olive presses in advance and, when the

reason came, was able to charge his own price for reletting them. The moral drawn was that philosophers can be as worldly wise as other men if they so choose. To demonstrate the contrary, that philosophy's chief glory is its abstraction from the world, Plato tells how Thales fell into a well while stargazing and was laughed at for studying the heavens to the neglect of what was at his own feet.

The best attested fact is his prediction of the eclipse which stopped the battle between the Lydian Alyattes and the Mede Cyaxares. The date 585 B.C. suits the chronology now that Herodotus has been shown to have erred slightly in implying that Astyages succeeded Cyaxares in 594. Thales could not have had the knowledge to predict accurately the locality or character of an eclipse. Hence the feat was isolated and apparently only approximate; Herodotus speaks of his foretelling the year only. The use of the Babylonian saros for this purpose has been convincingly denied by O. Neugebauer (*Exact Sciences in Antiquity* [1951]). All that his Babylonian contemporaries could say was that an eclipse was either excluded or possible, and this sufficed for their astrological aims. From their records, Thales could well have said that an eclipse was possible in the year which ended during 585. The coincidence that it occurred during a crucial battle and was nearly total would give him in retrospect an exaggerated reputation as an astronomer.

Thales was specifically credited with five geometric theorems, as follows: (1) that a circle is bisected by its diameter; (2) that angles at the base of an isosceles triangle are equal; (3) that opposite angles of intersecting straight lines are equal; (4) that the angle in a semicircle is a right angle; and (5) that a triangle is determined if base and angles relative to base are given. The real extent of his mathematical achievement is almost impossible to assess in view of the ancient habit of crediting particular discoveries to individuals with a general reputation for wisdom. The fifth theorem is associated with the feat of measuring the distance of ships from shore, for which an empirical rule would have sufficed.

Moreover the requirements of "proof" vary according to period; of the third theorem Eudemus himself said that, although it was discovered by Thales, Euclid provided the scientific proof. Yet we may well believe that the first Greek philosopher improved on Egyptian techniques of land measurement in the way described by Proclus, who after saying that Thales introduced geometry from Egypt adds that "he made many discoveries himself and laid the foundation for his successors, attacking some problems in a more universal way and others more empirically."

The claim that Thales was the founder of European philosophy rests primarily on Aristotle, who says that he was the first to suggest a single material substratum for the universe, namely water, or moisture. The reason, Aristotle suggests, was that moisture is pre-eminently the origin and sustainer of life: vital heat is generated by moisture; semen and all nourishment must contain it. Aristotle frankly admits that he writes from hearsay; whatever Thales may have written had long been lost. Nevertheless both the statement and Aristotle's conjectural reasons are probably true in substance. The origin of all things from water was a commonplace of Babylonian and Egyptian mythology (the tradition of Thales' sojourn in Egypt is strong) and can be traced among the Greeks as far back as Homer's description of Ocean as the genesis of all things. Thales had consciously renounced myth, but its legacy remained.

We need not doubt that he was in method and intention rational. The dualism of matter and life was in the future, and what he seems to have sought was a single principle, both origin of the world and permanent ground of its being, to explain the mutability and multiplicity of phenomena. It must therefore be not only material but also author of change, that is to say, something self-changing; for, as the more mature Aristotle complained, these early Milesians did not distinguish matter from active cause. But, in Greek eyes, what changed or moved itself was alive, had psyche ("soul"). Hence, we may guess, Thales' choice of the substance which seemed to have the closest connection with life, as moisture did in Greek thought both then and later. The whole

universe was a living organism, nourished by exhalations from water.

Consonant with this are other statements which Aristotle found traditionally attributed to Thales, that "the magnet has soul because it attracts iron" and that "all things are full of gods." The latter Aristotle connects with the belief that "soul is mingled in the whole." Diogenes Laërtius quotes Aristotle as saying also that Thales attributed life even to the inanimate, arguing from the behaviour of the magnet and of amber.

Of Thales' cosmology nothing is known but the statement quoted by Aristotle that the earth floats on water. To the historian of science, his significance lies not so much in the primacy of water (though some, like Sir Charles Sherrington in *Man on His Nature* [1940], have shown that this is by no means an absurd idea) as in the attempt to explain nature by the simplification of phenomena and the search for causes within nature itself rather than in the caprices of anthropomorphic gods. For cosmic unity as such, mythical precedents may again be quoted. That "all things come from one" was an early belief in Greece as in other lands; the original unity of earth and sky is crudely reflected in Hesiod's *Theogony*. Through the mists of later anecdotal tradition the true stature of Thales emerges only dimly, but as far as can be judged both he and his successors Anaximander and Anaximenes are important as constituting a bridge between the worlds of myth and reason. The ideas of these philosophers appear to some historians as remarkable anticipations of modern science, to others as transparent rationalizations of myth. They could not free themselves entirely from the inherited cosmic framework, but in their approach to it, in their critical spirit and in their determination to produce a simple, rational scheme employing only natural causes, they took a step whose future importance can scarcely be overrated. See also references under "Thales" in the Index volume.

**THALLIUM**, a metallic chemical element, was discovered in 1861 by Sir William Crookes (*q.v.*) during a spectroscopic examination of the flue dust produced in the roasting of seleniferous pyrites. He observed a green line foreign to all then known spectra and concluded that the mineral contained a new element, which he named thallium, from the Greek for "a green twig." Crookes presumed that his thallium was something of the order of sulfur, selenium, or tellurium; but the French chemist Claude-Auguste Lamy, who anticipated him in isolating the new element (1862), found it to be a metal. The pure metal is not commercially important, but thallium salts have a number of laboratory and industrial uses (see *Salts: Uses*, below).

The symbol for Thallium is Tl. Its atomic number is 81, and its atomic weight is 204.37. Thallium has naturally occurring stable isotopes of mass numbers 203 and 205. It occurs in four rare minerals: crookesite,  $(\text{CuTlAg})_2\text{Se}$ ; lorandite,  $\text{TlAsS}_2$ ; vrbaitite,  $\text{TlAs}_2\text{SbS}_5$ ; and hutchinsonite,  $(\text{TlAgCu})_2\text{S} \cdot \text{As}_2\text{S}_3 + \text{PbS} \cdot \text{As}_2\text{S}_3$ . It is also found in minute quantities in various pyrites, some of which are processed for other purposes; e.g., the manufacture of sulfuric acid. In such cases thallium is often concentrated in the flue dusts or chamber muds—the usual raw-material sources of thallium.

For the extraction of the metal from chamber mud, the latter is boiled with water, which extracts thallium as sulfate. From the filtered solution the thallium is precipitated as chloride by addition of hydrochloric acid, along with more or less lead chloride. The mixed chlorides are boiled down to dryness with sulfuric acid to convert them into sulfates, which are then separated by boiling water, which dissolves only the thallium salt. The filtered solution yields thallium (replaced in the salt by pure metallic zinc); electrolysis is also employed. The (approximately pure) metallic sponge thus obtained is washed, made compact by compression, fused in a porcelain crucible in an atmosphere of hydrogen, and then cast into sticks.

**Properties.**—Thallium is a bluish-white metal that resembles

Physical Properties of Thallium

Density at 20° C, g. per cc.	11.85
Melting point °C	303.5
Boiling point °C	1,457.
Radius of ion, $Tl^+$ , Å	1.15
Radius of ion, $Tl^{++}$ , Å	0.95
Coefficient of linear expansion at 20°C, per °C	$8.24 \times 10^{-6}$
Ionization potential of gas atom, volts	
1st electron	6.07
2nd electron	20.32
3rd electron	29.7
Resistivity at 20° C, ohm-cm.	$18.1 \times 10^{-6}$
Potential at 25° C for $Tl \rightleftharpoons Tl^+ + e$ , volts	0.336
$Tl \rightleftharpoons Tl^{++} + 2e$ , volts	-0.719

lead in most of its physical properties; *i.e.*, it is very soft, malleable, and of low tensile strength. Two crystalline forms are known with a transition temperature of 226° C.

The elements gallium, indium, and thallium comprise Subgroup IIIB in the periodic table (*see* PERIODIC LAW). Thallium has the following electron arrangement in the incomplete orbits (O and P):  $5s^2, 5p^6, 5d^{10}, 6s^2, 6p^1$ . It readily loses one of its valence electrons to form thallous, the +1 oxidation state, or all three electrons to form thallic, the +3 state. Thallous ion resembles divalent lead in the formation of insoluble chlorides and iodides; it is also quite similar in many of its properties to the alkalis, since it is a +1 ion of similar size. Thallic ion resembles aluminum and gold but has less pronounced acid-forming properties, since it is a larger +3 ion.

Metallic thallium is easily oxidized to the thallous state. It tarnishes in air, forming an oxide film that readily dissolves in water; upon prolonged contact with air and water the metal dissolves to form a thallous hydroxide solution. Thallium at red heat reacts with water to liberate hydrogen and form thallous oxide,  $Tl_2O$ . Thallium dissolves in nitric acid and sulfuric acid; it dissolves less readily in hydrochloric acid, which precipitates the insoluble chloride. It unites directly with all the halogens.

**Salts.**—*Properties and Preparation.*—Thallium forms two series of salts: thallous, in which the metal is univalent; and thallic, in which it is trivalent. The thallic salts are much less stable than the thallous. All thallium salts are poisonous, producing symptoms somewhat resembling those of lead poisoning.

Thallous hydroxide,  $TlOH$ , is most conveniently prepared by decomposing a solution of the sulfate with barium hydroxide. It crystallizes from its solution in long yellow needles,  $TlOH$  or  $TlOH \cdot H_2O$ , which dissolve in water to form an intensely alkaline solution that acts as a caustic and greedily absorbs carbonic acid from the atmosphere.  $TlOH$  is also alcohol soluble. Unlike the alkalis, it readily loses its water at 100° C, and even at the ordinary temperature, to form the monoxide  $Tl_2O$ , a poisonous black powder. The peroxide  $Tl_2O_3$  is formed when the metal is heated in air or oxygen at 500°–700° C, by the action of hydrogen peroxide upon alkaline solutions of thallous salts or by heating thallous nitrate. It decomposes into the monoxide and oxygen above 800°. The corresponding hydroxide,  $TlO \cdot OH$ , is very unstable. A thalothallic oxide,  $Tl_2O \cdot Tl_2O_3$  or  $TlO$ , is also known.

Thallium monochloride,  $TlCl$ , is readily obtained by adding hydrochloric acid to the solution of any thallous salt. It is a white precipitate similar in appearance to silver chloride, which it also resembles in turning violet in the light. It fuses below redness into a (yellow) liquid that freezes into a hornlike flexible mass. It is also formed when the metal is burned in chlorine. One part of the precipitated chloride dissolves at 0° C in 500 parts of water, and in 40 parts at 100° C. It is less soluble in dilute hydrochloric acid. Thallium trichloride,  $TlCl_3$ , is obtained by heating the monochloride with chlorine under pressure or by saturating a suspension of the monochloride in water with chlorine; when anhydrous it is a crystalline mass that melts at 24°. It forms several double salts; *e.g.*, with hydrochloric acid and the alkaline chlorides. The chlorine is not completely precipitated by silver nitrate in nitric acid solution, the ionization apparently not proceeding to all the chlorine atoms. The mixed chlorides  $TlCl \cdot TlCl_3$  are also produced by the regulated action of chlorine on the monochloride.

Thallium monoiodide,  $TlI$ , similarly obtained as a yellow precipitate, requires 16,000 parts of cold water for its solution. The yellow crystals melt at 190° and when cooled assume a red colour,

which changes to the original yellow on standing. Thallium triiodide,  $TlI_3$ , is interesting because of its isomorphism with rubidium and cesium triiodides, a resemblance that suggests the formula  $TlI(I_2)$  for the salt, but T. M. Lowry and A. J. Berry (1928) showed that it does not give the reactions of a thallous salt, and when dissolved in methyl alcohol, it behaves as a binary electrolyte; *i.e.*, as  $(TlI_2)I$  or as  $Tl[TlI_2]$ .

Thallium monobromide,  $TlBr$ , a light yellow crystalline powder, is formed analogously to the chloride. Mixed bromide-iodide crystals have a high infrared transmission; lenses, windows, and prisms ground from the crystals are used in instruments for the detection and measurement of infrared radiation.

Thallium carbonate,  $Tl_2CO_3$ , more nearly resembles the lithium compound than any other ordinary carbonate. It is produced by exposure of thallous hydrate to carbon dioxide and therefore is obtained when the moist metal is exposed to the air. It forms resplendent monoclinic prisms, soluble in water. The bicarbonate is not known.

Thallous sulfate,  $Tl_2SO_4$ , forms water-soluble rhombic prisms that melt at a red heat, decomposing with evolution of sulfur dioxide. It unites with aluminum, chromium, and iron sulfates to form alums (*q.v.*). It also forms double salts of the type  $Tl_2SO_4 \cdot (Mg, Fe, \text{ or } Zn) SO_4 \cdot 6H_2O$ . Thallous sulfide,  $Tl_2S$ , is obtained as a black precipitate by passing hydrogen sulfide gas into a thallous solution. It is insoluble in water and in the alkalis but readily dissolves in the mineral acids. Thallic sulfate,  $Tl_2(SO_4)_3 \cdot 7H_2O$ , and thallic nitrate,  $Tl(NO_3)_3 \cdot 3H_2O$ , are obtained as colourless crystals on the evaporation of a solution of the oxide in the corresponding acid. The sulfate decomposes into sulfuric acid and differs from aluminum sulfate in not forming alums.

**Uses.**—Mixed crystals of  $TlBr$  and  $TlI$  are used in infrared radiation transmitters, and  $Tl_2S$  is a component of infrared-sensitive photocells.  $Tl_2O$  imparts high refractive properties to optical glass. In chemical analysis,  $TlOH \cdot H_2O$ ,  $Tl_2O$ , and  $Tl_2SO_4$  are useful in testing for ozone,  $TlClO_3$  in testing for carbon disulfide, and  $Tl_2SO_4$  in testing for iodine in the presence of chlorine.  $TlCl$  is a catalyst in chlorination.  $Tl_2SO_4$  is a commercial rodenticide and insecticide. Artificial gems are coloured with  $Tl_2O$ , and  $TlNO_3$  is a "green fire" ingredient of fireworks. Thallium acetate,  $TlC_2H_3O_2$ , provides high-specific-gravity solutions for the refining of ores by flotation.

**Analysis.**—All thallium compounds volatile or liable to dissociation at the temperature of the flame of a Bunsen lamp impart to such flame an intense green colour. The spectrum contains a bright green of wave length 5,351 Å. From solutions containing it as thallous salt the metal is easily precipitated as chloride, iodide, or chloroplatinate by the corresponding reagents. Hydrogen sulfide, in the presence of free mineral acid, gives no precipitate; ammonium sulfide precipitates  $Tl_2S$  from neutral solutions as a dark-brown or black precipitate insoluble in excess of reagent. Thallic salts are easily reduced to thallous by means of solution of sulfurous acid and are thus rendered amenable to the above reactions. Thallous chloride can be titrated by potassium iodate in moderately concentrated hydrochloric acid solution.

**THALLOPHYTA**, an old phylum or division name formerly used to designate a large and very diverse group of relatively simple plants, from microscopic algae, bacteria, and fungi to one straplike seaweed that forms massive networks along certain coasts. The term is an artificial one and is used for convenience in referring to any of the lower plants that lack differentiation of the body into true roots, stems, and leaves. In one modern and commonly accepted classification the thallophytes are arranged in ten phyla or divisions: seven of algae and one each of bacteria, slime molds, and fungi. *See* PLANTS AND PLANT SCIENCE *Classification of Plants; Morphology of Plants; ALGAE; BACTERIA; FUNGI; PALEOBOTANY; SLIME MOLDS.*

**THAMES**, the principal river of England, rising in several headstreams among the Cotswold Hills in Gloucestershire. Its traditional source is Thames Head, at about 356 ft. (109 m.) O.D. (Ordnance Datum, or mean sea level as defined by Ordnance Survey) in the parish of Coates, 3 mi. (4.8 km.) SW of Cirencester; but claims have been advanced for Seven Springs, the source of the River Churn, situated at nearly 700 ft. (213 m.) O.D., 4 mi. S of Cheltenham. The Thames follows a winding course east and bounds parts of Gloucestershire, Wiltshire, Oxfordshire, Berkshire, Buckinghamshire, Surrey, Kent, and Essex. It bisects Greater London. Its length from Thames Head to where it enters the North Sea at the Nore is about 210 mi. (338 km.). Its width increases gradually to 125 ft. (38 m.) near Oxford, 250 ft. at Teddington, 750 ft. at London Bridge, and 2,100 ft. at Gravesend, below which the estuary expands rapidly to 5½ mi. between Sheerness and Shoeburyness. The average gradient from source to tidal water is 30 in. per mi. (47 cm. per km.). In the following paragraph the figures in parentheses denote distance in miles above London Bridge, 164 mi. (264 km.) from the source.

The upper course meanders eastward over a broad vale amid pleasant rural scenery. The main tributaries enter the left bank from the Cotswolds: the Churn near Cricklade (154), the Coln near Lechlade (143), the Windrush at Newbridge (127), and the Evenlode below Eynsham (119). At that point the Thames bends northward around the wooded Wytham Hill before turning sharply south to join the Cherwell at Oxford (112). It then flows between low limestone hills on to a clayey lowland where the Ock (right) enters at Abingdon (104) and the Thame (left) at Dorchester (95). The river proceeds southward, and near Goring (85) its valley, now deep and steep-sided, breaches the chalk uplands and divides the Chilterns from the Berkshire Downs. At Pangbourne (81) the Thames turns abruptly eastward and winds, beneath beautifully wooded slopes, across the southern edge of the Chilterns. On the right bank the Kennet enters at Reading (74) and the Loddon near Shiplake (69). Below Maidenhead (50) the landscape becomes flatter, apart from the isolated chalk knoll at Windsor (43). Notable tributaries feed both banks: the Colne (left) at Staines (36), the Wey (right) near Weybridge (30), and the Mole opposite Hampton Court. Below Teddington Lock (19) the Thames is tidal and truly metropolitan; yet as long stretches of its channel are narrowed artificially, particularly by stone embankments, it remains riverlike and is spanned by numerous bridges, the lowest being London Bridge and, ½ mi. below it, the lifting Tower Bridge. From there to Greenwich and Newham (about 10 mi.) ocean commerce and quayside monopolize the waterfront, and tunnels (Rotherhithe, Blackwall, Greenwich, and Woolwich—the last two for pedestrians only) replace bridges. Along the next section of the river to Tilbury and Gravesend (about 16 mi.) estuarine marshes alternate with large industrial (Thames-side) establishments and chalk bluffs; the Purfleet-Dartford Tunnel, linking Essex and Kent, provides a means of bypassing London. Below the main outpost at Tilbury the wide estuary is coastal in nature.

The river was referred to by Julius Caesar as Tamesis and by early English chroniclers variously as Tamis, Tamisa, and Tamenis. The term Isis for the upper Thames appeared in the mid-14th century and was concocted by academics who, considering Tamesis to be a compound of Thame and Isis, wrongly thought Thames applied only to the river below Dorchester.

**Evolution of Drainage Pattern.**—The Thames has a complicated history that defies simple analysis. Its basin consists of two distinct components: above and below the Goring Gap, respectively. Above Goring it is developed on Jurassic strata, of which the older Liassic and oolitic series form the higher rim, notably in the Cotswolds. But this basin is itself subdivided transversely into upper and lower parts by a line of hills, partly of Corallian limestone, that is breached by the Thames at Oxford. The drainage of the upper or outer part thus converges on Oxford. Its watercourses occupy wide valleys, many of which continue as wind gaps (valleys unoccupied by streams) across the watershed into the basins of the Warwick Avon and the Severn. Typical is the wind gap across the Cotswolds near the upper Coln followed by

routes to Cheltenham. The lower or interior part of the upper basin, that immediately above Goring, consists of a lowland separated only by weak divides from the drainage of the Wash and Bristol Avon. Below Goring the Thames Basin consists of chalk that has been downfolded into a syncline with a west-east axis and covered with Eocene sands and clays. In this area the west-east Kennet appears to represent the master stream.

The origin of the Thames system can probably be traced back to a thick cover of Mesozoic rocks, especially chalk, stretching far westward from their present outcrop and draining eastward. Later, perhaps in mid-Tertiary times, this cover was affected by folding, which created a syncline along the line of the present Kennet-Thames, together with an anticline in the Wealden area to the south and perhaps also in the Midlands to the north. From the peripheral upfolds individual streams drained toward the proto-Kennet-Thames. The direction of some Cotswold headstreams may represent the trend of this early drainage. Because the Cretaceous cover was gradually eroded away from the higher rim of the drainage basin, the exposure of clay beds allowed subsequent tributaries to develop on clay vales at the foot of limestone scarps. Thus, beyond the outermost Jurassic scarp, the lower Severn and a river flowing to the Trent (in reverse direction to the present Warwick Avon) developed headward and captured drainage from headstreams of the Thames. Similarly, within the Thames Basin the upper Thames developed slowly as a west-east subsequent stream and diverted to itself southward-flowing Cotswold streams. Eventually the whole of this intricate pattern was profoundly influenced by the Ice Age with its climatic changes. Ice invaded the north and northeast of the basin and in periods of melt and of heavy rain great floods poured down the valleys, which were successively deepened and finally left encumbered with gravel and alluvium upon which the present relatively small rivers meander. In addition, the lower Thames was pushed southward from the vale of St. Albans to a position near the southern Chalk rim. Throughout the Thames system, tiers of river terraces were formed, often of sand and gravel of economic value. In the Middle Gravels of the Boyn Hill terrace at Swanscombe, Kent, was found a fragmentary skull dating from the interglacial period and closely related to *Homo sapiens*.

**River Regulation.**—A permeable basin and all-year rainfall give the Thames a regular flow. Normally its volume is lowest in summer, when evaporation is greatest, but spates may occur any time, particularly from October to May. The monthly averages of the daily mean natural discharge at Teddington, from a drainage basin of 3,810 sq.mi. (9,868 sq.km.), vary from 4,877 cusecs (cu.ft. per sec.) in January to 1,067 cusecs in August, the mean being 2,683 cusecs (1 cusec = 0.0283 cu.m. per sec.). When the daily flow reaches 8,400 cusecs, or bank-full stage, the low-lying parts of the valley floor on the nontidal Thames are temporarily inundated, and during heavy floods the daily flow may exceed 19,000 cusecs. On the tideway, floods occasionally menace embanked areas when fairly high river spates coincide with strong spring tides. During rare prolonged droughts the daily natural flow at Teddington may drop below 300 cusecs, and water supplies are threatened. However, the freshwater Thames is Britain's best regulated river, and its control by the Thames Conservancy, established in 1857, involves mainstream navigation and drainage and water supply throughout the whole basin above Teddington. The Thames is the chief source of water supply for London and its western suburbs and also supplies districts centred on Oxford and Faringdon. Its tributaries the Wey, Kennet, Cherwell, and Windrush are also drawn upon. The Thames Conservancy enforces freedom from pollution and also regulates fisheries, which provide numerous coarse species and trout in some stretches. The tidal Thames below Teddington to the sea (a distance of 92 mi., including five dock systems covering more than 4,000 ac. [1,600 ha.]) was put under the control of the Port of London Authority in 1908. The Lea has its own Conservancy.

**River Traffic.**—After 1624 the Thames was made navigable for barges to Oxford and beyond, but navigation remained difficult until 1771 when the Thames Commissioners began to construct pound locks above Staines. From 1810 to 1815 the corporation

of London built similar locks between Staines and Teddington. Later improvements allowed boats drawing three feet to reach Lechlade. Some barge traffic uses the river above Teddington, especially to Kingston. Regular steamer services ply daily in summer between Oxford and Kingston, also from Westminster upstream to Kew, Richmond, and Hampton Court, and downstream from Tower Pier to Tilbury, Southend, Margate, etc. There are also water-bus services between Putney and Greenwich, and ferry services operate from Woolwich (in Greenwich) to North Woolwich (in Newham) and from Gravesend to Tilbury. Pleasure craft abound, and registrations with the Thames Conservancy include thousands of motor-driven launches, cabin cruisers, houseboats, and smaller craft.

Most of the canal connections of the freshwater Thames are derelict, but on the tidal reaches the intense commercial activity enlivens water links. The Grand Union Canal to the Midlands remains active. The Lea is navigable to Hertford (27 mi. [43 km.]), and the Stort to Bishop's Stortford (13 mi.); pleasure craft predominate, but barges regularly ascend the Lea to Ware (25 mi.) and the Stort to Sawbridgeworth (9 mi.). The Thames Navigational Service, operating from Gravesend, provides navigation surveillance between that part of the Thames below London Bridge that forms one of the most important commercial waterways in the world. See LONDON.

Thacker, *The Thames Highway: a History of the Locks and Weirs* (1920); L. T. C. Rolt, *The Thames from Mouth to Source* (1951); B. Waters, *Thirteen Rivers to the Thames* (1964). (R. P. Be.)

**THANA**, a town of Maharashtra State, India, and the headquarters of the district of the same name, lies 21 mi. (34 km.) NE of Bombay, of which it forms a suburb. Pop. (1961) 101,107. Buildings of interest in Thana include the Old Fort, the Jain and Kaupineswar temples, and the Portuguese Cathedral. There are also two hospitals and several high schools. One of the earliest Portuguese settlements in India, Thana was formerly an important port and trading post.

**THANA DISTRICT** has an area of 3,658 sq.mi. (9,474 sq.km.) and a pop. (1961) of 1,652,678. Bordered by the Western Ghats on the east and the Arabian Sea on the west, the district consists of lowland intersected by hilly tracts. Near the coast the land is low and fertile, and the area is thickly populated. The district is well watered and wooded. The only rivers of any importance are the Vaitarna, on which the Bombay Corporation has constructed a dam, and the Ulhas. The Vihar and Tulsi lakes, formed artificially in the area of very heavy rainfall, supply Bombay city with water. The main agricultural crops are rice and raggee, a millet. Inferior cereals, oil seeds, and pulses are also grown. The chief industries are the manufacture of salt by evaporation; cotton, woolen, and silk milling; bone milling; and rope, machine tool, and paint manufacture.

The territory comprised in the district (apart from Salsette Island) formed part of the dominions of the Peshwa and was annexed by the British in 1818. (M. R. P.)

**THANET, ISLE OF**, the northeastern corner of the county of Kent, Eng., facing the North Sea, location of the resort towns of Margate and Ramsgate (developed as fashionable watering places during the later 18th century) and of the smaller resorts of Broadstairs, Westgate, and Birchington. The "isle" is 10 mi. (16 km.) long from east to west and 14 mi. (23 km.) wide, being separated from the mainland by two branches of the River Stour, one with the ancient name of Wantsum. It is composed for the most part of a chalk ridge culminating in the North Foreland.

The former sea channel was guarded north and south on the mainland by the Roman forts of Regulbium (Reculver) and Rutupiae (Richborough), and despite medieval reclamation and the silting up of Sandwich Harbour, it remained open for small boats until the 16th century. In ancient times a ferry crossed the Wantsum at Sarre, but about 1485 a bridge was constructed with causeways across the marshes. The southern end of the channel was at Ebbsfleet, the reputed landing place of Hengist, c. A.D. 449, and

evidence of Jutish settlement has been found at Ozengell near Ramsgate and elsewhere. Thanet suffered later from Danish raids, during which Minster Abbey was destroyed.

Its location made Thanet of maritime importance, and much of the island was associated with Dover or Sandwich and lay within the liberty of the Cinque Ports. It contains the municipalities of Margate and Ramsgate and the urban district of Broadstairs and St. Peter's. (Fx. H.)

**THANJAVUR (TANJORE)**, a town of Madras State, India, and the headquarters of the district of the same name, is on the western side of the Cauvery Delta, 218 mi. (351 km.) SSW of Madras by rail. Pop. (1961) 111,099. The town was the royal residence of the Cholas until after the reign of Rajaraja I (A.D. 985–1014), when his successor, Rajendra Chola, shifted the capital, and Tanjore lost much of its importance. It was revived, however, by the Naiks (Nayak) about 1549. They built two forts, the smaller of which, with its walls and moat, is still well preserved. Later the town became the capital of the Maharashtra dynasty. In 1799 the surrounding country was ceded to the British by Raja Sarfoji, and on the death of his son Sivaji in 1855 without male issue, the town also passed to the British. One of Thanjavur's most notable features is the great Brihadisvara Temple (also called the Raja Raja Temple, after its founder), a monumental piece of architecture, with a tower more than 200 ft. (60 m.) high, decorated with pillars and statues. In the northeastern section of the smaller fort is the Schwartz Church, founded about 1778 by the missionary C. F. Schwartz. There are several other churches in Thanjavur, which was the headquarters of some of the earliest Protestant missionaries in India. The Old Palace, which consists of a large group of buildings, houses the Tanjore Art Gallery, the Mahal Library, with a large collection of rare manuscripts and books, and the Raja Sarfoji Arts College (1955). There is also a government medical college in the town.

**THANJAVUR DISTRICT** has an area of 3,740 sq.mi. (9,687 sq.km.), and a population (1961) of 3,245,927. Predominantly agricultural, the district is the granary of Madras State, having 1,500,000 ac. (600,000 ha.) under rice. Since water is available in the delta throughout the year, multiple cropping, especially of rice, is practised. Vadapathimangalam has a modern sugar mill, and there are steel-rolling mills at Nagapattinam. The district is famous for silk weaving, the Kornad saris with their gold and silver borders being particularly well known. Other industries include rice milling, the manufacture of mats, brass vessels and lamps, musical instruments, and inlaid copperwork. The existence of numerous temples and the highly advanced nature of the works of art they contain bear witness to the high cultural level of the region 2,000 years ago. Thanjavur District is also the birthplace of the south Indian classical dance the Bharata Natyam. (G. Kn.)

**THANKSGIVING DAY**, an annual national holiday in the United States, Canada, and a few other countries, celebrates the harvest and other blessings of the past year. Although days of thanks for special occasions were celebrated in the first years of Virginia's settlement and harvest celebrations are as old as civilization itself, it is generally acknowledged that the first Thanksgiving Day celebration in America occurred when the Pilgrims, by order of Gov. William Bradford, held a three-day festival to commemorate their harvest in the autumn of 1621. Edward Winslow, in a letter of Dec. 11, 1621, described the celebration:

Our harvest being gotten in, our Governor sent four men on fowling, that so we might after a more special manner rejoice together, after we had gathered the fruit of our labours. They four in one day killed as much fowl as, with a little help beside, served the Company almost a week. At which time, amongst other recreations, we exercised our arms, many of the Indians coming amongst us, and amongst the rest their greatest king, Massasoit with some 90 men, whom for three days we entertained and feasted. And they went out and killed five deer which they brought to the plantation and bestowed on our Governor and upon the Captain and others.

Despite this early beginning, Thanksgiving Day was not celebrated in America as a regular national holiday for more than two centuries after 1621. Massachusetts Bay Colony's first civil Thanksgiving was observed July 8, 1630, after the safe arrival of

all of John Winthrop's ships, but it was 1660 before the celebration for harvest gathering became a regular annual event in that colony. Harvest festivals became an annual custom in Connecticut in 1649 and in Plymouth in 1668, but Rhode Island did not adopt the practice until the Revolution. By the end of the 18th century, however, celebrating Thanksgiving Day was an institution in all New England. During the Revolution, days of thanks were set aside for special occasions and Nov. 26, 1789, was proclaimed by George Washington as the first national day of thanksgiving. But the day still had not become an institution. Gradually the idea was spread to the West by New England migrants as well as by the energetic urging of Mrs. Sarah J. Hale, the early-19th-century editor of the famous *Godey's Lady's Book* of Philadelphia, a widely read women's magazine. Though the South was hesitant to adopt this New England custom, by the middle of the 19th century most of the Northern states had accepted the idea, and President Lincoln proclaimed a national harvest festival on Nov. 26, 1863. From that time on, Thanksgiving Day has been an annual holiday in the United States, proclaimed yearly by the president and by the governor of each state. Except for 1939 and 1940 when Pres. Franklin D. Roosevelt set the day a week earlier to lengthen the interval between Thanksgiving and Christmas, Thanksgiving Day had always been named as the last Thursday of November. In 1941 Congress passed a resolution making the fourth Thursday of that month a national legal holiday.

The meaning of Thanksgiving and the manner of its celebration have changed little since the day of the Pilgrims. Thanksgiving was and still is basically a home festival with religious overtones. Never celebrated on a Sunday, the day is generally commemorated with special church services by all faiths, but the main emphasis is on the gathering of family and friends for a gay and plentiful feast. As in the days of the Pilgrims, turkey is the traditional meat for that day, and other autumnal dishes, such as pumpkin pie and plum pudding, stress the harvest theme. The flavour of the day has been immortalized in literature and poetry; one of the best known poems, by Lydia Maria Child, begins with the familiar lines: "Over the river and through the woods, to grandfather's house we go. . ."

See Ralph and Adelin Linton, *We Gather Together: the Story of Thanksgiving* (1949). For Virginia's protest about Massachusetts' first Thanksgiving, see Virginius Dabney, "That Mythical 'First Thanksgiving,'" *Saturday Evening Post* (Nov. 29, 1958). (B. K. B.)

**THANT, U** (1909– ), Burmese writer and UN secretary-general, was born Jan. 22, 1909, in Pantanaw, Maubin district, not far from Rangoon, Burma. (Strictly speaking, "U" is not part of his name but is an honorific title comparable to "Mr." or "Honoured Sir," though the literal meaning is "uncle." The Burmese do not use surnames at all.) He was educated at the National High School, Pantanaw, and at the University of Rangoon, but had to leave the university to help support his family. At the university U Thant became acquainted with Thakin Nu (later U Nu), who was to become prime minister when Burma gained its independence.

After dropping out of the university, U Thant returned to the National High School in his home town as a senior teacher and later as headmaster. During the Japanese occupation of Burma in World War II, he was a member of various educational committees, and in Aug. 1943 he returned to Pantanaw to rebuild the high school, which had been damaged during the war.

After World War II, U Thant was persuaded by U Nu and by Gen. Aung San, then leader of Burma, to enter government service. In Sept. 1947 he went to the information department and in 1949 became secretary, ministry of information and broadcasting. He was in 1952–53 a member of the Burmese delegation to the United Nations and, after serving his government in various capacities back in Rangoon, in 1957 he became Burma's permanent representative to the UN. Throughout these years he traveled widely, accompanying Prime Minister U Nu on various good-will missions and to international conferences.

He was elected acting secretary-general of the United Nations on Nov. 3, 1961, and a year later was elected secretary-general to serve until November 1966. Devoutly Buddhist, U Thant

sought to apply the personal disciplines of detachment and concentration to get to the heart of problems at the UN. Neutralist by practice as well as inclination, he criticized at different times both West and East for actions he considered inimical to world peace. When the U.S. and the U.S.S.R. could not agree on a secretary-general after Dag Hammarskjöld's death (Sept. 18, 1961), U Thant was the one person on whom they could compromise. The U.S.S.R. had earlier demanded a three-man secretaryship (the so-called troika). U Thant continued the Hammarskjöld tradition by exercising discretion, by keeping himself available to all national representatives, and by trying to forestall problems before they became insurmountable. Like his predecessor, he considered the UN to be first and last a world instrument for sustained negotiation. (G. C. LL.; P. M. A. L.)

**THAPSUS, BATTLE OF**, fought on Feb. 6, 46 B.C. (April 6 by the uncorrected Roman calendar), between the forces of Julius Caesar and the supporters of Pompeius (Pompey). After the battle of Pharsalus (*q.v.*) the Pompeians mustered in North Africa under the command of Pompey's father-in-law, Q. Metellus Scipio, who commanded about 14 legions and 15,000 cavalry and was supported by Labienus and the Numidian king Juba. Caesar rushed what troops he could to the east coast of modern Tunisia and hung on until more could join him. When he had eight legions he was ready to face the Pompeians. He blockaded Thapsus (on modern Ras Dimas, 8 mi. E of Moknine) by land and sea. The city was approached by two necks of land on either side of a large lagoon. Scipio first tried to relieve the town by the southern approach, but was balked by a fort which Caesar had built there. Leaving Afranius and Juba to block that corridor, Scipio marched by night round the west side of the lagoon and drew up his army in the northern corridor. Caesar sent some ships to threaten the enemy's flank and left a covering force in his own rear; he then advanced to meet Scipio. His men were even more eager to engage than he was: when a trumpet sounded the charge, the centurions vainly tried to hold the men back, but the line swept forward. They drove back Scipio's left, and when his right gave way, his centre was rolled up. In the moment of victory Caesar's men got completely out of hand and spared none of the enemy, of whom about 10,000 perished. Within three weeks of this victory Caesar had gained control of all Roman Africa.

See T. Rice Holmes, *The Roman Republic and the Founder of the Empire*, vol. iii, ch. 22 (1923). (H. H. Sp.)

**THARAUD, JÉRÔME** (1874–1953) and **JEAN** (1877–1952), French narrative writers and essayists whose topical journalistic stories of foreign lands did much to popularize and raise the standard of such literature. Their real names were Ernest (born at Saint-Junien, near Limoges, on May 18, 1874) and Charles (born at Saint-Junien on May 9, 1877), but the books on which they collaborated were signed jointly Jérôme and Jean.

*Les frères Tharaud*, as they came to be known, won fame when they were awarded the Prix Goncourt in 1906 for their novel *Dingley, l'illustre écrivain* (1902), dealing with British imperialism in South Africa and prompted by Rudyard Kipling. They traveled widely and were much concerned with world problems, their pursuits leading them from Algeria (*La Fête arabe*, 1912) to Morocco (*Marrakech, ou les seigneurs de l'Atlas*, 1920), from Syria (*Le Chemin de Damas*, 1923) to Austria (*Vienne la rouge*, 1934), and from Hungary (*Quand Israël est roi*, 1921; *When Israel Is King*, 1924) to Spain (*Cruelle Espagne*, 1937). They were particularly interested in the Diaspora (*q.v.*), and their most important writings—including *L'Ombre de la Croix* (1917; *The Shadow of the Cross*, 1918), *Un Royaume de Dieu* (1920), and *La Jument errante* (1933)—are on Jewish topics. They were equally inspired by French life and ideas, as is evident from their historical essays (*e.g.*, *La Tragédie de Ravallac*, 1913) and their novels *La Maîtresse servante* (1911) and *Les Bien-Aimées* (1932). Their clear, sober style reflects the outstanding truthfulness of their reports. They became members of the Académie Française, Jérôme in 1938, Jean in 1946. Jean died in Paris on April 9, 1952, and Jérôme at Varengeville-sur-Mer (Seine-Maritime) on Jan. 28, 1953.

See J. Bonnerot, *Jérôme et Jean Tharaud, leur oeuvre* (1927). (Em. H.)

**THAR DESERT (INDIAN DESERT)**, a large arid area in the northwest of the India-Pakistan subcontinent, extends for about 400 mi. from southwest to northeast and has a maximum width of about 225 mi. The desert is limited to the south by the Great Rann of Cutch. To the west lies the valley-plain of the Indus and to the northwest that of the Sutlej. Northeastward the desert fades into Punjab state, India, while the southeastern limit is marked by the Aravalli range (*q.v.*) running from southwest to northeast. The greater part of the desert lies in the Indian state of Rajasthan of which it occupies nearly half. The remainder is in West Pakistan where the desert occupies a large part of the former princely state of Bahawalpur and the old province of Sind.

The area slopes on the whole from the foothills of the Aravallis, at about 1,000–1,500 ft., northwestward to the margin of the Indus plain at 200–300 ft., or southward to the Rann of Cutch. There are no permanent rivers except the Luni in the southeast, but channels follow the general slopes and in the extreme west are former channels of the Indus.

The whole area is probably underlain by the crystalline complex of the Indian peninsula outcropping near the desert margins in the Aravallis. The greater part of the desert surface is occupied by sands, silts and loesslike material, the finer-grained making excellent soil where water is available. The name *Thar* ("desert or sandy waste") refers to the sand hills accumulated by the prevailing winds. Saline dust is transported from the Indus delta and the Rann of Cutch and deposited in hillocks. In the southwest long ridges (Sindhi, *bhils*) are found aligned from southwest to northeast parallel to the prevailing winds. In the northeast these give place to transverse dunes of barchan type though somewhat irregular. Toward the Rann, dunes more or less permanent may rise to 200 ft. above the general sandy surface; inland they are smaller and the landscape tends toward a low plateau of deep, loose moving sand.

The average rainfall is 15 in. a year and on the western margins near the Indus this drops to less than 5 in. The rainfall is unreliable and varies greatly from year to year, the average variability from the mean being more than 30%. Toward the north there may be occasional falls from sudden storms associated with cold-weather cyclones. In the centre and south most rain comes in the normal Indian wet season, June to September. The range of temperature, both diurnal and annual, is large. In the cold season, November to February, days are warm but nights cold so that in the north frost occurs despite the January mean of 12.7° C. –21° C. (55° F. –70° F.). Essentially tropical plants are thereby excluded. The land heats up from March onward and, as there is insufficient rain to exercise a cooling influence, June and July are normally the hottest months despite the southwest winds. The average daily temperature in July exceeds 32° C. (90° F.) and afternoon readings are up to 53° C. (127° F.). Dust storms are common at the periods of reversal of pressure about April–May and October.

**Natural Resources and Irrigation.**—Surface deposits everywhere are impregnated with salt derived from the evaporation of subsoil brine and the accumulation of salt particles blown from the Rann. On the eastern margins of the desert are the Rajasthan salt lakes. Lake Sambhar, the largest, lies in a closed depression in the Aravalli schists with a surface at 1,184 ft. Its maximum spread is 90 sq.mi. and during a normal monsoon it averages 4 ft. deep in the middle but is dry the greater part of the year. The upper 12 ft. alone of saliferous silt forming its bed represents a salt reserve of about 54,000,000 tons. The salt is extracted and railed to Sambhar at the eastern end of the lake.

Gypsum also occurs on the margin of some of the lakes. In southwest Sind and Khairpur on the edges of the Indus alluvial plain, where the alluvial clays are uncovered or covered by only a thin layer of sand, large shallow expanses of water known as *dhands* occur in the hollows or *talis* between the sand hills. They are fed by rainwater percolating through the sand and emerging as springs (*sims*). The spring water is usually fresh and gives rise to a fringe of vegetation. Saline *dhands* yield salt and gypsum; alkaline *dhands* supply the mineral trona which is the basis of the soda industry of Khairpur.

The vegetation of most of the desert is an open scrub. The

moving sand dunes are bare; saline hollows are marked by a halophytic vegetation but there is excellent grass on the sweet damp bottoms after rain. This affords fodder for numerous cattle, sheep, goats and camels and accounts for the location of the scattered villages. In good seasons bajra millet is grown to eke out a milk diet. Village industries based on coarse wool, camel hair and leathers play a considerable part in the economy of the area and reach notable proportions in the small towns, such as Jaisalmer and Bikaner, or the larger centre of Jodhpur.

Jodhpur has an airport and can be reached by rail; some of the old desert tracks are motorable but no main road crosses the desert and the east-west railway in the south is disused.

A major power and irrigation project was designed to reclaim large areas in the northern part of the desert. A dam and associated hydroelectric plant were built on the Sutlej river near the village of Bhakra. Eight miles downstream the Nangal dam (completed in 1954) provides storage for the Sirhind canal from which the dry areas on the Punjab-Rajasthan border are irrigated. Lower down the Sutlej, after it has been reinforced by the waters of the Beas, the Rajasthan canal (constructed in the 1960s) runs from the Harika barrage right through the northwestern part of the Thar desert. Though this canal is well within Indian territory, Pakistan objected that it diverts water which formerly fed the great canals branching from the Sutlej at Ferozepur (controlled by India). These are the lifeblood of much of Bahawalpur as well as of part of the Bari doab west of the river in Pakistan. However, in 1961 India and Pakistan reached a waters agreement.

(L. D. S.)

**THARRAWADDY**, a town and district in the Pegu division of Burma. The town lies 68 mi. (109 km.) NW of Rangoon by rail. Pop. (1953) 8,977. The district (area 2,784 sq.mi. [7,211 sq.km.]; pop. [1962 est.] 823,459) stretches from the Irrawaddy River on the west to the crest of the forested Pegu Yoma on the east. It thus comprises on the west an alluvial plain through which the railway runs and which is well populated and devoted to rice cultivation, and on the east almost uninhabited forest country with valuable teak forests and fuel reserves. Wild animals in the forests include elephant.

(L. D. S.)

**THARU**, a tribe numbering about 30,000 who live in small semipermanent villages apart from other groups in the Terai (*q.v.*; Tarai) tract of the Himalayan foothills, mainly in the Nainital (*q.v.*) District of Uttar Pradesh, India. They practise agriculture, raise cattle, hunt, fish, and collect forest products. Although closely resembling the Tibetans or Gurkhas of Nepal, the Mongoloid Tharu show genetic admixture with plains populations and have been largely affected by Indian culture. The five higher clans among the Tharu, which comprise about 80% of the population, claim to be Sisodiya Rajputs from Rajasthan; they refuse to marry members of the seven lower sections of Tharu (who also claim lordly status but are compelled to marry within their own sections). In contrast with the higher Hindu castes, Tharu use alcoholic beverages freely and eat beef. They approve polygyny, divorce, and secondary marriage with the deceased spouse's younger sibling. Notwithstanding that theirs is a patrilineal social system, Tharu women have property rights far beyond those recognized in Hindu society. Tharu generally employ no Brahmans but maintain their own priest-mediums in each village. The religious ceremonies, festivals, and beliefs of the Tharu are nevertheless largely Hindu in form and content.

See S. K. Srivastava, *The Tharus: a Study of Culture Dynamics* (1958); D. N. Majumdar, *Races and Cultures of India*, 4th ed. (1961) (M. MA.)

**THASOS**, a Greek island in the north of the Aegean Sea, about 4 mi. (7 km.) from the coast of Thrace and the delta of the Nestos River. Area 146 sq.mi. (379 sq.km.); pop. (1961) 15,916. The population is distributed in 11 villages, mostly at some distance from the sea; the chief one is Thasos (formerly Limin) on the north coast, on the site of the ancient capital. Zinc and other minerals are mined.

Herodotus mentions an early Phoenician settlement on Thasos, which had gold mines (no longer worked) and a peculiar cult of Hercules; Thracian settlement is also probable. In the early 7th

century B.C., Greeks from Paros colonized Thasos; they also owned gold mines on the mainland and planted cities there. Thasos joined the Delian League (q.v.), but disputes over the mines arose with the Athenians, who, after a siege of two years (465–463), compelled the Thasians to destroy their walls, surrender their fleet and their mainland possessions, and pay an indemnity and an annual contribution: in 450 this was 3 talents, but from 446 to 445 about 30 talents, after some of the mainland had been restored. During the Peloponnesian War Thasos revolted from 411 to 407, and after Athens' defeat the Spartan admiral Lysander seized Thasos (403). It joined the second Athenian League c. 375. Philip V of Macedonia seized it (202), but it was freed by the Romans in 196 B.C.

Thasos was under Latin rule from 1204 until its capture by the Turks in 1455. The Turks ruled it almost continuously until 1912; from 1813 to 1902 it belonged to the Turkish governors of Egypt. During the First Balkan War the Greeks captured Thasos, and by the Treaty of London (1913) its cession to Greece was confirmed.

The ancient city was excavated by the French School at Athens (from 1911), and its walls and general plan are now clear.

For the history of Thasos and for recent excavations, see *Études thasiennes* (École Française d'Athènes; 1944–).

**THATON**, a town and district in the Tenasserim division of Burma. The town (pop. [1962 est.] 136,394), formerly the capital of the Talaing kingdom and a seaport, now lies about 10 mi. (16 km.) from the sea. It is 35 mi. (56 km.) NW of Moulmein.

THATON DISTRICT formerly had an area of 4,870 sq.mi. (12,613 sq.km.) but has been reduced to a small but well-populated coastal strip between the Karen State and the sea. Area 1,909 sq.mi. (4,944 sq.km.). Pop. (1962 est.) 435,410. Excellent road metal is quarried at Mokpalin. Martaban is the southern terminus of the railway from Rangoon via Pegu and faces Moulmein across the mouth of the Salween River. (L. D. S.)

**THATTA** (TATTA), a town in the Hyderabad division of West Pakistan and the headquarters of the district of the same name, is situated 7 mi. (11 km.) from the right bank of the Indus River and about 50 mi. (80 km.) E of Karachi. Pop. (1961) 12,786. The town is built on a slight rise in an alluvial valley at the foot of the Makli Hills. In the 16th century it was the capital of the Samma dynasty in lower Sind and formerly had a much larger population. It has many remarkable monuments, including a fine Juma mosque, built by the Mughal emperor Shah Jahan, and the tombs of Mirza Jani Beg and Diwan Sulfa Khan. Thatta is connected by a 13-mi. (21-km.) road with Jungshahi on the Pakistan Western Railway.

THATTA DISTRICT (area 6,933 sq.mi. [18,112 sq.km.]) had a population of 301,886 in 1951; this had increased to 361,733 by the time of the 1961 census. The district occupies the Indus Delta and the strip of land between the river and the highlands north-east of Karachi. Formerly a part of Sind Province, Thatta District (with Hyderabad, Dadu, and Tharparkar) became part of the Hyderabad Division when Sind Province was dissolved in October 1955. Large-scale excavations in the district, at Bhamore, about 30 mi. (48 km.) from Karachi, have revealed ruins located on an eminence about 30 ft. (9 m.) high. The ruins are thought to be those of a settlement of considerable importance. The settlement was well planned, with lanes and blocks of houses with stone foundations and mud-brick structure arranged around open courtyards. (K. S. Ad.)

**THAYETMYO**, a town and district in the Magwe division of Burma. The town lies on the right bank of the Irrawaddy, opposite Allanmyo, 35 mi. (56 km.) N of Prome. In 1962 the population was estimated to be 59,055. Both towns developed as British frontier stations between independent Upper Burma and British Lower Burma. Thayetmyo became well known for its silverwork. It was founded in 1306.

THAYETMYO DISTRICT has an area of 4,626 sq.mi. (11,981 sq.km.); pop. (1962 est.) 352,893. The heart of the district is an undulating plain bisected by the Irrawaddy, much of which is covered with *Acacia* thorn scrub passing into dry forest on ridges rising from the plain and to true forest in the Arakan Yoma west

and the Pegu Yoma east. Cultivated patches have the usual dry zone crops of sesame, peanuts, and cotton, with some rice and tobacco. Innumerable white pagodas crown every rise and hill spur. South of Thayetmyo is a hill of limestone, and the discovery of a natural gas field about 1930 led to the development of a cement industry. (L. D. S.)

**THEACEAE**, the tea family, an important group of dicotyledonous shrubs or trees, with 16–18 genera and more than 200 species, chiefly tropical and subtropical, in both hemispheres. An important genus is *Camellia*, wholly Asiatic, with 50 or more species, among them tea, *C. sinensis*; the cultivated camellia, *C. japonica*; and the Chinese tea oil plant, *C. drupifera*.

*Stewartia*, *Franklinia*, and *Gordonia* species, all native to Asia, are often cultivated for ornamental purposes. The family is represented in the southern U.S. by two species each of *Stewartia* and *Gordonia*, sometimes called camellias, and *Franklinia* (*Franklinia alatamaha*), a beautiful fall-blooming tree. *Ternstroemia*, with 90 or more species, and *Eurya*, with 100 or more species, occur in both hemispheres. See TEA; Botany; CAMELLIA.

**THEATRE (ARTICLES ON)**. The article THEATRE is concerned with the dynamics of drama—the evolution of the various forms of stage presentation, and the ideas and methods that animate the modern stage. DRAMA discusses the origins of the dramatic arts and gives a historical review of dramatic literature from ancient Greece, Rome, and India to the Broadway and West End of today.

The activities involved in bringing a script to life before an audience are treated in ACTING, DIRECTION AND PRODUCTION. The changing standards by which theatrical values have been judged are discussed in DRAMATIC CRITICISM. The contributions of dramatists to national literatures are evaluated in such articles as AMERICAN LITERATURE; ENGLISH LITERATURE; FRENCH LITERATURE.

Various forms of dramatic art discussed in the surveys mentioned above are represented also by individual articles—for example: BALLET; COMEDY; COMMEDIA DELL'ARTE; KABUKI THEATRE; MASQUE; MUSICAL COMEDY; NŌ DRAMA; OPERA; PAGÉANT; PANTOMIME; SHADOW PLAY.

Additional articles on forms of theatrical presentation include CIRCUS; MINSTREL SHOW; MUSIC HALL AND VARIETY; PUPPETRY; VAUDEVILLE.

Articles dealing with technical aspects of the theatre include COSTUME DESIGN, THEATRICAL; MAKE-UP (STAGE, MOTION PICTURE AND TELEVISION); MASK; STAGE DESIGN; STAGE LIGHTING; THEATRES (STRUCTURES).

MOTION PICTURES gives a comprehensive survey of motion-picture writing, directing, and technology. Sections on animated cartoons and educational films are included, as well as discussions of methods of distribution. Other mechanical media for drama are treated in BROADCASTING and TELEVISION.

A series of articles deals with individual theatrical organizations—for example: ABBEY THEATRE; COMÉDIE FRANÇAISE; FEDERAL THEATRE PROJECT; FOLIES-BERGÈRE; GROUP THEATRE; MOSCOW ART THEATRE; OBERAMMERGAU; THEATRE GUILD (NEW YORK).

Among the articles on theatrical lore and activities are CONJURING; FOOL; PUNCH; SCARAMOUCHE; and VENTRILOQUISM.

Many biographical articles—for example, those on Shakespeare and Garrick—review the work of the great playwrights and actors in the perspective of their times.

The Index, in addition to listing complete articles on theatrical topics, guides the reader to subjects covered in individual sections and passages.

The following articles are suggested as a minimal reading program for an introduction to the history and basic methods of the dramatic arts: ACTING, DIRECTION AND PRODUCTION; DRAMA; DRAMATIC CRITICISM; MOTION PICTURES; TELEVISION: *Television Broadcasting*; and THEATRE.

**THEATRE**, the place in which dramatic entertainments are presented (in Greek called *theatron*) and, by extension, the activity comprising both the dramatic performances themselves and the work of all who are responsible for presenting them to audiences. This article surveys the theatre, past and present, in all

of its aspects. The article is best supplemented by readings in the biographies of dramatists, actors and others in the order of their mention here. For detailed information about places of performance, see THEATRES (STRUCTURES); for the drama considered primarily as a literary form, see DRAMA and articles on the various national literatures; and for the arts of dramatic representation, or stagecraft, see ACTING, DIRECTION AND PRODUCTION; COSTUME DESIGN, THEATRICAL; MAKE-UP (STAGE, MOTION PICTURE AND TELEVISION); STAGE DESIGN; STAGE LIGHTING.

In this article each of the following main topics is treated chronologically:

- I. General
  1. Introduction
  2. Actor and Society
  3. Origins
- II. The East
- III. The West
  - A. Antiquity
    1. Greece
    2. Rome
  - B. Christian Revival
    1. International Drama of the Medieval Church
    2. Medieval Minstrelsy and Pageantry
    3. Renaissance, Reformation and Counter-Reformation
  - C. Classical, Baroque and Romantic Reaction
  - D. Supplementary Arts
    1. Opera
    2. Ballet
    3. Mime, Pantomime, Vaudeville and Music Hall
  - E. The American Theatre
- IV. 20th Century
  1. Asia
  2. Great Britain
  3. Ireland
  4. U.S.S.R.
  5. Germany
  6. France
  7. Other European Countries
  8. British Commonwealth
  9. South Africa
  10. United States
  11. Latin America
  12. Drama Festivals

## I. GENERAL

**1. Introduction.**—When the word theatre is employed in the extended modern sense, descriptive epithets like Greek, Chinese, Elizabethan and Restoration, used in conjunction with it, serve to characterize not only the style of acting, building, costume and setting used in the theatre of the nation or period of history specified but even the style of written texts, together with the complex structure of commercial organization, government regulation and social relations. Theatre is, then, a style of dramatic art individual enough in its theory and practice to warrant description by a special label; "Indian theatre," "medieval theatre," "theatre in the round" define whole subjects either as homogeneous categories or periods of dramatic history, or as identifiable styles.

These styles are evolved through the cross-fertilization of national and historical artistic traditions in theatre practice, as exemplified in England or France by the adoption during the 17th century of Italian Renaissance landscape scenery, or in Germany by the 19th-century vogue for Shakespeare or during the present century by W. B. Yeats's interest in the Japanese *nô* play and the public enthusiasm for the Russian ballet presented by Sergei Diaghilev in Paris and London. The physical shape of stage and auditorium, too, in the course of about 2,000 years, has had a direct influence on the sort of play devised for performance: this is clearly seen when Sophocles' *Antigone*, *Electra* or *Oedipus Rex* are compared with modern versions of the same stories (e.g., by Jean Anouilh, Hugo von Hofmannsthal, Jean Cocteau) where the large role played in the original by a numerous chorus is adapted or omitted to conform with the physical conditions of modern theatres, which are both smaller in size and more intimate in the actor-audience relationship provided.

**2. Actor and Society.**—In any concept of the word "theatre" larger than that restricted to timber, bricks and mortar, the centre is the actor. It is on him that the author must depend if his own

scenario or text is to reach the audience as a living action. It is on him that the audience must depend as the instrument through whom the author's ideas are fully manifested in word, gesture and deed. Theatre, in the sense of a building, only acquires a *raison d'être* as a place for actors to perform in front of spectators. This is as true of the inanimate puppet and marionette theatre, and of the filmed drama or of the mechanically projected radio and television play, as it is of the animate theatre where, in opera, ballet or play, human actors encounter their audiences in person at every performance. All dramatic art, therefore, regardless of national or period label, takes its essence from the mimetic talent of the actor and its quality from the use to which this talent is put by the society that develops and rewards it.

The quality of the individual theatre will be particular to the society and will reflect that society's own level of development and standards of civilization. Great periods of achievement in the theatre have generally tended to coincide with or to follow immediately upon great national achievement, as the theatrical vitality of Periclean Athens, of Elizabethan England, of Louis XIV's France or of Scandinavia in the late 19th century illustrates. By contrast, a civilization with a marked addiction to ostentation and material values is likely to reflect this in a theatre dominated by spectacle and vulgarity, as may be seen in the decadence of Roman drama, of the English theatre during the 19th century or in the implications in the name of Hollywood in the latter half of the 20th century.

This relationship between the actor and the society of which he forms a part is itself responsible for the pattern of birth, growth, climax and decay repeated within every period of the theatre's history distinct enough to be identified by such special designations as "Greek tragedy" or *commedia dell'arte*. The creative initiative is invariably spontaneous and supplied by amateurs either directly as performers or indirectly as patrons. Any degree of popular success is then sought by professionals for reward until a point is reached where technical perfection or virtuosity can be admired in its own right. Exploitation of the commercial possibilities by the actors, their sponsors or both, in such a manner that financial gain outweighs care for art, quickly undermines professional integrity; artistic standards decline until that theatre loses first the respect, then the support of its patrons, and finally, its identity. Outstanding examples of the amateur initiative are the dance dramas of primitive peoples, the essays in perspective scenery and stage machinery of the 16th-century Italian *intermedi* and of the Stuart masque in England, and the American arena theatre movement that began in Seattle at the University of Washington and was later endowed on a professional basis in Washington, D.C.

Another cyclic feature often repeated in the theatre's evolution is the sacrifice of an initial reliance on emblematic conventions of presentation to the gradual but increasing requirements of verisimilitude and spectacle for its own sake. This change is characterized by proportionately mounting production costs and by the sacrifice on the part of the actor of much of his own liberty of action to the whims or exigencies of painters and technicians; and in motion pictures and television to the mechanical restrictions imposed by microphones and cameras as well.

The actor's standing with society at large depends upon that of the theatre as a whole. In a primitive community he gained the approbation of his fellow men for contributing his own unusually developed human talent for mimicry to their service; in a more sophisticated society his translation to professional status may make him an object of envy to many and of censure to those others who claim that it is improper to esteem, let alone reward, any form of pretense. Acting and actors, when the activity is self-conscious enough to merit description under these terms, have thus always been a debatable asset to society; Plato thought them worthless hypocrites, while in England between 1648 and 1660 they were termed "caterpillars of the Commonwealth." At other times they have been valued highly enough to be thought worth fostering, as Aristotle believed them to be, or to warrant receipt of training, salary and pension at the expense of government, as in the U.S.S.R.

**3. Origins.**—This ambivalence in the actor's status and reputa-

tion in society derives directly from the way in which his mimetic talent is first harnessed to the needs of society. This talent is instinctive in every child and brings him from infantile to mature social behaviour. Linked with this instinct to explore by imitation and thus to enlarge experience is an egocentric concept of the individual's relationship to other people. The two in conjunction result in the self-assertion that distinguishes the personality of one individual from that of another. Once pretense by imitation has acquired this degree of self-consciousness, a distinction between "the performer" and "the beholder" becomes possible; each is only satisfied by the presence of the other. Theatre is born when this co-operative act of make-believe extends to cover consecutive imitated action. The attention of the beholder is arrested and held by the nature and accuracy of the imitation, while the ability of the imitator is enlarged by knowledge gained from the experience.

Theatre in this most elementary of forms is inarticulate, depending neither on a formal text nor on improvised speech; known as mime (*q.v.*), imitation through gesture and movement of the face and body is common in this state to all peoples and requires only an open space for its enactment.

Historical study has revealed that theatre in this natural form is quickly harnessed by all primitive peoples in seeking explanations for what is mysterious and unknown in their own environment. Attempts are made to establish contact with the sources of power in nature that appear most destructive and hurtful to a primitive people: excessive heat and accompanying drought, rain and floods, extreme cold and other violent phenomena occasioning acute emotional anxiety to tribe or individual. The form that these attempts take is usually mimetic imitation of the phenomenon feared, or imitation of objects observed to be related to that phenomenon in nature; the consuming power of fire is sought from contact with the ashes or the secret of fertility from contact with evergreens; the rhythms of nature as heard and seen in the movement of the wind or the sea are copied and simulated in dance (*q.v.*). With such means as these an appeal is made to the spirits or deities deemed to govern the elements to assist or at least to refrain from harming the supplicants. Disguise of the person in the shapes of nature and projection of the person into dance patterns imitating its movements are thus among the earliest distinctive components of theatre; a third essential is an open space where the disguised dancers may undertake their ritual.

The obstacle between these preparations and direct communication with the hidden god is consciousness of pretense in the whole nature of the action; the disguises adopted, being no more than emblems of the nature of the god, cannot be expected to induce the power required to permit speech with the god. A state of heightened emotional awareness has to be stimulated to obliterate this restrictive consciousness. It is here that the performers are called upon to generate an emotional response of an extraordinary kind in the beholders by accentuating the rhythmic quality of the dance patterns. The union between mortals equipped with nothing better than the crude symbols of the god's nature and behaviour and the controlling mind of the god himself, which in everyday life appears impossible, then becomes possible in the frenzy or ecstasy of the dance rhythms; and in this union of the spirit, involving the submergence of the individual in the whole, fear is overcome and anxiety allayed. Famine and plague may recur, but given the means of further communication the god can always be consulted.

The fear that is common to all individuals is that of death; it is thus to be expected that in their dance rhythms primitive peoples have been most attracted to those aspects of nature in which rebirth noticeably grows out of death; that is, to the solstices and the seasons. These phenomena account for the most persistent of all early theatrical imitations—the slaying of the god and his subsequent resurrection. The ancient rites associated with Osiris in Egypt derived from this assumption, and traces of it may be seen in the sword dances and mummers' play of the folk in northwestern Europe.

These rituals were designed to propitiate the forces of nature for past misdemeanours or to seek their assistance in future strug-

gles, but many rites of a similar kind were evolved to give thanks for assistance received. These expressions of joy, however, were not marked by any such clearly defined narrative pattern as that of the dying god; the most notable characteristic was simply excess as exemplified for the whole western world by the proverbial Saturnalian orgy of Roman times or, in the Christian era, by the licentious Feast of Fools, when what E. K. Chambers described as "the peasant beneath the cassock" revealed his nature.

The transition from these dance rituals (specimens of which may still be observed in New Guinea and in parts of Africa) to a species of pretended action that incorporates a long and formal narrative with accompanying dialogue is difficult to discuss since it was not within the means of persons making this transition to record its details. They could only transmit what they knew, verbally or by example, to those who followed them and who added to and embroidered what they inherited with spontaneous inventions of their own. It is, therefore, to anthropologists and experts in the primitive religions of the world that one must turn for information. Relics survived in regular drama in the continued use of masks; in the relationship between actor and chorus in the earliest Greek tragedy and the earliest liturgical plays of the Christian Church, which reflected that of priest and congregation; in the elaborate emblematic headdresses, costumes and gestures of the Indian and Chinese classical theatre; and in the presence of an altar as the focal centre of the earliest Greek and Christian dramatic action. Above all there may be discerned in the written texts of tragic drama a continuance of earlier efforts to explain the inexorable laws of nature to fearful mankind, and in all early comedy a deliberate release of high spirits, which, in mocking everything artificial, pompous or unnatural, extols the liberty and bounty of nature.

Tragedy and comedy (*qq.v.*) are the two primary types of theatrical experience that dramatic art, however sophisticated the place or time, has continued to provide. The more serious kind has always preserved affinities with its religious origins, while the more frivolous kind has been liable to degenerate into forms offensive to a highly developed sense of public decency. It is the exploitation of the latter forms of simulated action by professional actors for commercial reward in return for the social recreation provided (in contrast to the spontaneous amateur theatre of worship) that has caused both actors and the theatre to be attacked from time to time as vicious, immoral and better suppressed.

## II. THE EAST

The country with the earliest reliable record of a dramatic tradition more advanced than ritual dancing is India, its history being traceable to about A.D. 100. Java, Bali and Burma all possess a notable dance drama, but it is from China and Japan that the most highly formalized dramas have survived into current use, despite contact with the western world. Indian classical theatre (Sanskrit) was virtually extinguished as a result of the Muslim invasions of the 10th century and after; but enough information, in the form of play texts and treatises about their staging, survived for attempts at revival to be made during the 19th century. Not enough is yet known in the west about the early history of the oriental theatre to ascertain the degree of interaction between the various dramas of distinct national origin; the Japanese theatre, however, owes as direct a debt to the Chinese theatre as the American theatre does to that of western Europe.

The transition from dance drama to regular plays in India, China and Japan was made in each instance through the Buddhist religion and aristocratic patronage, distinct genres with written texts being in existence in India by the 2nd century A.D., in China by the 6th and in Japan by the 14th. In all three countries actors have had a mixed reputation, some enjoying the friendship of princes and others being regarded as little better than beggars or criminals. In India, actors (*nata*, "a dancer") formed an identifiable class or caste in society and female roles were played by men until the 20th century. In all three countries an actor's training started in early youth, and a high degree of skill was required not only in dancing but also in singing, mime and acrobatics.

Where theatre buildings and the stage conventions employed in

them are concerned, common practice is again evident. Temples and palaces adapted to suit the actor's needs sufficed initially and, in India, probably continued to do so; at least there is no evidence of buildings constructed to accommodate dramatic representations alone. In China and Japan, however, actors acquired wealth and position enough to become independent of their patrons and to build regular theatres for popular audiences. The typical Chinese theatre is a rectangular building containing a large projecting stage (almost square) backed by a curtained or painted wall containing two doors. The *nō* stage in Japan (and the kabuki stage, which is adapted from it) also projects into the auditorium and is square (18 × 18 ft.). A penthouse roof (adapted from the Shintō temple of origin) projects over this stage and is supported by pillars. (See *NŌ DRAMA: Staging*; *KABUKI THEATRE*.)

Theatres of the east have no scenery in the western sense of the word. Place is identified by emblems, some being permanent fixtures like the four stylized pine trees (one large, three small) of the *nō* stage, others taking the form of large stage properties like the arched gate or painted flags of the Chinese theatre: change of place is identified by the mime of the actors, by special properties like the Chinese tasseled horsewhip and by the shifting of properties in the audience's view by stage assistants, who sit on the stage throughout the action. These architectural and scenic conventions bear a marked resemblance to those used in European theatres of the middle ages and early Renaissance (see below).

A similar reliance upon an emblematic manner of presentation is seen in the costuming and acting style of oriental plays. Masks are rare. Only the first actor (*shite*, *shitey*) wears one in *nō*. The painting of the skin, however, and particularly of the face, was regular in all three theatres and developed to a quite remarkable degree in China, where the *hua-lien* or painted face denotes character through both the particular lines and colours of the make-up. Many have been standardized, and the actor is trained to be competent in the style, colour and scale of beards, applied jewels, lines and spots appropriate to particular characters.

Headdresses and articles of clothing also serve to demonstrate character and temperament. In Indian drama gods and princes are immediately identifiable by their exceptionally elaborate headdresses, while in China and Japan animal headdresses (especially tiger heads) and plumes worn above the painted face are appropriate to warriors of high rank. Colour symbolism plays as important a part in costume as it does in make-up: robes of rich silks and satins are often so elaborate as to require long practice in the wearing of them if they are to be maneuvered with any semblance of agility or grace.

Contact with the west did not at first make any difference to these traditions except in India, where, under British rule, a growing European interest in Sanskrit literature led to a revival of classical plays in Bengali translation (1857 and after). This revival was possible because of the survival of both the play texts and the *Natyasastra* of the Brahman priest Bharata, a detailed treatise on the composition and production of plays written during the 3rd century A.D. and as important a document for the study of Eastern drama as the writings of Aristotle and Vitruvius on Greek and Roman drama have proved to be in the west. Other, later commentaries embroidered on Bharata's work but added little that was new. Archaeological research has brought to light a few pictorial representations of early performances.

Music has always formed an important element in the oriental theatre. Instrumental music conjoined with religious ceremonies introduced the leading player, who sang or spoke an explanatory prologue. In Japan, this function is shared between the second actor (who enters first) and the first actor; in China, the protagonist of the drama undertakes this task; in India, it was done by the leader of the company (*Sutradhara*). The orchestra (dominated by flutes, drums, cymbals and gongs) not only accompanies chanted dialogue but also sets a tempo that is carefully followed by the actors in their movements.

Formal differentiation of genres exists in the eastern theatres. Japanese kabuki and *nō* are the most obviously distinct; but in China wu (the military play) and wen (plays with civilian subject matter) are traditionally as different. Distinctions in the Indian

theatre, as between *nataka* ("heroic legend") and *prahasna* ("farical stories"), are also real. Japanese *nō* is itself divided into categories. Nowhere, however, is there any close correspondence to western genres (with the possible exception of melodrama), and in India the happy ending was invariable. Act and scene divisions of the kind familiar to the west are normal to all oriental plays, but unity of place has never been a question of consequence in a drama where episodic narrative is the dominant characteristic of structural form and where the technical virtuosity of the actor in a familiar role has always counted for more than novelty of plot or formal compactness. Western motion pictures, when introduced into eastern countries, found substantial popular support because of their episodic treatment of narrative; such techniques were already familiar to audiences.

Photographic realism, however, while easily copied by film makers of eastern nationality, has struck a severe blow at the imaginative emblematic conventions of the oriental stage, which by the 1960s had lost popular support to films and television.

### III. THE WEST

The history of theatre in the west differs from that of the east in two important respects. In the west there was the phoenixlike rebirth of organized drama in the middle ages after about 400 years of seeming death, and in the 20th century the quest for verisimilitude in dramatic imitation culminating in the mechanical reproduction of performances on film—a western invention subsequently exported to the east.

The most important single feature distinguishing the drama of the first phase, from the 5th century B.C. to the 6th century A.D., from that of the second phase, from the 10th century A.D. to the 20th, was the intervening influence of Christian philosophy and ritual. The theatre of the first phase was Greek in origin, spread to Italy and from there was transplanted east, west and south to the frontiers of the Roman empire; northward it penetrated into Austria, Germany and even Britain. The decline and fall of the theatre, already sapped from within by a growing dependence upon costly spectacle coinciding with objections to the nature of the spectacle raised by Christians on moral grounds, was one of the results of the barbarian invasions.

Although many theatres of the Hellenistic period are still standing in the 20th century, the new drama of Christian inspiration that began to take life and shape in the 10th century did not make use of these buildings; nor did it imitate the sophisticated forms of Greek and Roman regular drama since the new texts, acting and stage conventions were supplied by amateurs. Not until the 15th century was any serious concession made to earlier practice. The full-scale revival of Greek and Roman play forms and architectural concepts that followed in the 16th and 17th centuries was consequently distorted from the start; difficulties arose because a Christian society was seeking to emulate a product of non-Christian inspiration and because this society lacked adequate knowledge of stage practice in anything but late Roman theatres. The imitation consciously pursued was thus unconsciously based on a phase of Greco-Roman theatre already decadent in its addition to spectacle and in its relation to society. The result, in every European country that already possessed a theatre of Christian inspiration, was to create a divorce between the two; i.e., between a religious stage commanding popular support and a *commedia erudita*, or academic theatre, of interest only to the aristocracies of intellect and courtly privilege. This divorce coincided in time with the wars of religion; and, since the popular theatre was religious, the divorce took a form in each European country that followed the pattern of ecclesiastical government. In Italy divorce between the two became total by the end of the 15th century; in Spain—because of close supervision and gradual modification by the Inquisition—it is scarcely discernible; in France, Germany, the Low Countries and England it was erratic. Censorship and suppression, however, are everywhere in evidence, the differences from one country to another being in timing and degree. In France the religious stage was dissolved by the edict of 1548; in England it had become impossible by 1590 for any play devoted to religious subject matter to be performed with

impunity. To the revival of Roman theatre, the court amateurs of European countries contributed something of their own—a pre-occupation with dance and song, which were developed respectively in succeeding centuries as ballet and opera.

Despite the immediate triumph of the academically inspired neo-classical theatre in the 17th and 18th centuries popular elements returned to it, the way being led by the *commedia dell'arte* (q.v.) in Italy and by sentimentalism in English drama of the late 17th century. The romantic revival championed by Diderot in France and Lessing in Germany restored some dignity to the popular theatre of earlier times but it did not recover for a theatre of situation, intrigue, manners and scenes the popular support previously accorded to the theatre of religious and heroic narrative with its emblematic conventions of presentation. The development of melodrama in the 19th century restored to narrative and action their earlier pre-eminence, but the theatre's ability to provide accompanying spectacle of a realistic kind was eclipsed by the potentialities of the motion picture, which came into existence by the beginning of the 20th century.

The commercial potentialities of film theatre were quickly realized. The technique of marrying sound to picture was perfected in the late 1920s, opening a national market for repeated showings of a single performance, which, with the additional accomplishment of providing subtitles and "dubbing" in foreign languages, was extended to include a world-wide market. Further wholesale changes in bringing plays to audiences, instead of obliging audiences to come to theatres, are similarly attributable to advances in scientific knowledge, the most notable being the invention of radio and television transmission and of processes for the recording of such transmissions.

#### A. ANTIQUITY

1. **Greece.**—As well as creating great dramatic masterpieces, the classical Greek theatre has left a notable legacy to posterity in the (1) distinctness of the three dramatic genres—tragedy, comedy (old, middle and new) and satyr play; (2) the size and shape of the theatre buildings; (3) the division of function within the drama between actors in the roles of characters and those serving as choric commentators interpreting between the protagonists of the stage action and the audience; and (4) the strongly characterized masks worn by the actors.

A relationship between religious festivals and the three forms of regular drama (particularly in the rites associated with the nature god Dionysus) is generally acknowledged by historians but evidence is lacking with which to define this relationship in any detail. The outstanding survival from the earliest Greek tragedy is the relationship among single actor, chorus and audience (the whole community), which parallels that among priest, initiates and congregation in religious ritual. The parallel is reinforced by the themes and structure of the earliest surviving plays. Tragedy, being concerned with the moral government of the universe, was strictly serious and formal; Aeschylus' *Oresteia*, for example, concerns crime and its consequences in terms of mortal and divine retribution. Comedy (i.e., old comedy), being contemptuous of all human attempts to behave as if mortals possessed the minds of gods, was joyous, robust and satirical; Aristophanes' *Lysistrata*, although deeply serious in its concern about war, still appears in the 20th century to be as uproariously funny as it is outspoken in the means suggested to prevent war's recurrence.

As Greek drama developed, emphasis shifted from divine and cosmic themes to mortal and microcosmic problems. H. D. F. Kitto has written that tragedy was formed, ennobled itself and lost its vigour while Athens was passing through the same processes; during this period, he points out, tragedy moved from communal to individual themes. Comedy underwent a series of equally clear transitions from broadly political (old comedy) to social satire (middle comedy) and then to a comedy of manners with stereotyped characters in plots dependent on intrigue and situation. Changes in theatre practice kept step with these thematic tendencies. Aeschylus called on the services of a second actor (both actors doubling in more than one part) and Sophocles on those of a third. Both of these authors tended to increase the

number of characters in their plays, and their successor, Euripides, went farther still in this direction. The chorus lost ground to the actors in number and function. The original dithyrambic chorus of 50 that Aeschylus inherited had been reduced in Euripides' lifetime to less than half the number, with nothing more to do than interpolate decorative lyrical odes as interludes in the action. In comedy, whereas Aristophanes used his chorus as formally as Sophocles, the new comedy of Menander used it for induction or the interpolation of songs for their own sake. The pursuit of realism brought with it a corresponding change in the nature of both stage language and setting. The earliest plays are made up of sequences of choral odes interrupted by "episodes" of speech for actors (e.g., Aeschylus' *Agamemnon*). Sophocles' plays were distinguished by the perfect balance achieved between choral and dialogue speech; the metrical rhythms are of the utmost importance and probably carry in them some reminder of the original choric movements.

The place of performance, initially a large dancing floor (orchestra), was elaborated first with a dressing room and then by extension and decoration of the *skene* thus created on a scale great enough to permit the use of revolving panels (*periaktoi*) bearing pictures designed to identify the place of action and other machines. Nevertheless, the Greek theatre was wholly emblematic, employing men to impersonate women, using masks to conceal the fact that one actor was playing more than one part, and identifying place by symbol. Moreover, in attempting any imaginative reappraisal of a Greek play in performance, it must be remembered that the auditorium seated 10,000–20,000 persons, all of whom looked down on the orchestra and thus saw at one time the geometrical patterns of the chorus dances and the magnificence of the landscape beyond the *skene*.

Aristotle's notes on dramatic composition in the *Poetics* and a list of prize-winning plays (*Didascalia*) written in the 4th century B.C. provide much knowledge of the historical development of drama in Greece and a careful appraisal of the theory of tragedy, its function and composition, as practised up till his own day. These notes were translated, summarized and commented upon in Latin in later centuries but did not circulate widely in the west in the Greek original until late in the 16th century.

2. **Rome.**—The only plays that survive as a basis of an appreciation of Roman theatrical tastes are the comedies of Plautus and Terence (2nd century B.C.), the tragedies of Seneca (probably written to be read, not acted) and a few fragments of pieces attributed to Ennius, Pacuvius and Accius of the 3rd and 2nd centuries B.C. There is the related evidence of a great many theatre buildings (most now in ruins) ranging from such small intimate edifices as may be seen at Verulamium (St. Albans) in England, at Taormina in Sicily or at Pompeii near Naples to such grandiose monuments as the well-preserved examples at Orange in Provence and Aspendus in Turkey. Horace, in his epistle to the Pisos (a work better known as *Ars poetica*, or "The Art of Poetry"), gives some picture of what the Romans expected of their theatre. Documentation of theatre architecture and machinery, however, is better than that surviving from Greece because of the preservation of Vitruvius' *De architectura* (1st century B.C.) and Pollux's *Onomasticon* (2nd century A.D.).

The affinities between Greek new comedy and that of Plautus, as well as those present in the two styles of theatre building, argue a marked continuity between Greek precedent and Roman practice. On the other hand, the lack of any corpus of tragic texts; the nomadic and comparatively professional quality of the Roman actor's status; the certainty of a raised stage in Roman theatres, which was of more importance than the orchestra; the use in theatres built during and after the 1st century A.D. of a drop curtain with the development of scenic effects that the curtain allowed; and the additional attention given to the comfort of the audience—all indicate a positive Roman attitude to theatre that was both mundane and commercially angled. This picture is reinforced by the knowledge that under imperial rule mime and pantomime based upon actors' improvisations and acrobatics came to dominate a theatre growing steadily more luxurious in its appearance and fittings at the expense of the dramatist. Mere

first instance both of these dramatic representations took place within the ritual of the Mass and were enacted by the choir. The initiative appears to have come from the duchy of Swabia in the 10th century, the text taking the form of a chanted Latin introit, *Quem quaeritis in sepulchro, O Christicolae?* The great religious houses of St. Gallen (now in Switzerland), Limoges and Fleury quickly elaborated these texts both musically and in the extension of subject matter, though treatment of Christ's Passion is conspicuously absent. Dramatic representation spread to areas as remote from one another as Dublin and Augsburg or Winchester and Florence, and

theatricality, exploited for the sake of display and for commercial gain, was substituted for the former religious, moral and artistic concerns of actors and audiences. With this change responsible people came to regard the theatre as unworthy of their attention.

In republican days, Roman comedy at least still possessed written texts and aimed at exposing vice and ridiculing folly in as amusing a manner as possible. A noisy crowd in holiday mood had to be silenced by the actors and its attention held against the competition of rival sports and festival attractions. The success of Plautus and Terence at least is demonstrated by the way in which their plays have held the stage in revivals, translations and remodelings. Even radio and television have deemed them worth reviving in translation, Plautus' *Mostellaria*, *Miles Gloriosus* and *Menaechmi* being among the most successful.

With the alienation of the writers, however, and the steady increase in purely spectacular extravagance and vulgarity it is easy to understand why early Christians should have been as contemptuous of theatrical performances and as hostile to the profession of acting as their writings and actions show that they were. The closing of the theatres in the 5th century A.D. after the triumph of Christianity within both eastern and western halves of the Roman empire did not result from any particular antipathy to regular drama; the early Christian Fathers within the empire were opposed to a form of dramatic art so debased through commercial exploitation as to have lost any relevance to the general good of society. Outside the empire they had to contend with dramatic rituals as yet too primitive to have acquired regular forms but the closer on that account to the primitive religions that Christianity was seeking to suppress. The theatre of the ancient world thus survived in fragments only like some river that has temporarily split itself into several channels: a selection of texts, a variety of disused buildings (useful as quarries), some theoretical treatises, and groups of itinerant mimics, singers and dancers exercising their talents illicitly wherever a patron or passer-by could be found to look and listen. The barbarian invaders from the north and east, possessing no regular drama of their own and speaking languages other than Greek and Latin, could not supply the initiative required to reunite these isolated components of former dramatic and theatrical traditions.

## B. CHRISTIAN REVIVAL

**1. International Drama of the Medieval Church.**—The first steps toward reunification were taken spontaneously and unself-consciously in the Christian liturgy; the festival of Easter and celebration of Christ's resurrection provided the occasion; the meeting of the three Marys with the angel at the empty tomb and the angel's announcement of the resurrection to them was the first elementary dramatic performance involving mime, and emblematic representation of person and place was repeated in connection with the miraculous birth at Christmas at the time of the winter solstice. In the

would seem to indicate that it was accepted as part of the church's missionary and instructional activities. It is not until the end of the 13th century that the Passion is treated fully or that the vernacular is preferred to Latin.

During 300 years of slow elaboration in these liturgical music plays, a code of symbols drawn from earlier liturgical practice and chant came to be applied to the performance of these plays; the code served as the basis for subsequent theatre practice in respect of acting, costumes and setting. St. Ethelwold, as bishop of Winchester, in his *Regularis Concordia* (c. 965–975) drew up rules for the acting of the *Quem quaeritis* ceremony in his diocese governing gesture, vestments and means of suggesting locale.

Similar information may be gleaned from the rubrics of service books all over Europe, though a great many of these were destroyed in the course of the Reformation. One of the fullest to have survived is the French *Festum Praesentationis beatae mariae* of Philippe de Mézières (1372), from which the wholly ritualistic and emblematic nature of these performances may easily be reconstructed. This text along with all others of importance is printed in Karl Young's *The Drama of the Medieval Church*. The gradual extension of the subject matter treated in these religious playlets led to an episodic narrative style with small regard to formality in respect of time, place or action. Thus in every respect this drama performed by priests for the enlightenment of worshippers openly admitted the pretense implicit in the representation.

This very important characteristic, so different from the 20th-century theatre practice which often uses every conceivable scientific device to pass off the pretense as the actual, applied with equal force to the vernacular adaptations of scripture in dramatic form that began during the 14th century. Known in Italy as *sacre rappresentazioni*, in Spain as *autos sacramentales*, in France as *mystères* and in England as miracle plays or (after 1800) as mystery plays, these performances were centred on Christ's Passion and were designed to stress the humanity as much as the divinity of Christ. Thus, while preserving in field, market place or town hall the same emblematic quality in performance as the liturgical play of cathedral or church interior, the highly ritualistic style of presentation was relaxed to accord better with the secular elements now preponderant in the narrative. Chant gave place to speech, church vestments were supplemented by contemporary costume appropriate to peasant or secular official, and scenic elements, specially made for the performance, became more decorative. The high seriousness of purpose remained, but comic elements, particularly in association with devils and peasant characters (e.g., Mak of the Wakefield second *Shepherds' Play* or Mrs. Noah of the Chester *Deluge*), obtained a place in the plays, assisted no doubt by the use of vernacular speech. The initiative for these cyclic dramas, which grew long enough to occupy anything from a day's duration (in York) to a week's (in London and Mons), probably must be credited to mendicant friars. Plays of similarly didactic and devotional purpose concerning the lives of

closely linked to festivals of the Christian calendar, themselves adapted from earlier folk festivals of the agricultural year—Christmas (winter solstice); Shrovetide, Easter and May day (advent of spring); Ascension, Whitsunday and Corpus Christi (summer solstice); St. Michael, and All Saints (harvest thanksgiving and autumn). Choice of a place of performance was governed by the mutual convenience of actors and audience: churches, where large enough; adjacent yards or cloisters where the churches were too small; market places, quarries, even playing fields; town halls, baronial halls, palace halls. The hierarchical stratification of medieval society was strictly observed in the provision of "standings" (and more rarely seats) and arrangements for the privacy and sight lines of spectators. Stages and auditoriums were as occasional as performances, with the notable exception of the "pageant waggon" stages used in the north of England that were carefully stored away for future use. Most religious plays were performed, as in Athens, by the local community for its own members. The actors received wages but were not professionals. Female parts were played by choirboys, though not invariably. The "wives of this town" presented the play of *The Assumption of the Virgin* in Chester. The cost was underwritten by both church and town; surviving expense accounts prove that the biggest single item was the cost of scenic units and winch machinery for flying angels and disappearing devils. Modern observers may be surprised at the endurance of audiences ready to

sit or stand all day for several days watching these simple but dignified and profound plays; the plays then had a rarity value augmented by long months of corporate preparation and heightened by a sense of occasion, both of which have been lost.

**2. Medieval Minstrelsy and Pageantry.**—An equally occasional but more nearly professional theatre that aimed at social recreation rather than religious edification grew up during the late middle ages among minstrel troupes in princely courts and the households of the lords spiritual and temporal. The troupe consisted of *jongleurs* ("troupeurs") who entertained with mime, music and circus acts, and whose social status and way of life were probably descended from those of the nomadic mimes of the Roman theatre; it was led by the *trouvère* ("troubadour"), a probable descendant of the Teutonic *scōp*, who held the rank of esquire and sang or recited *chansons de geste*. This theatre gave expression to song, dance and romance literature in mime for the pleasure implicit in these things rather than for any devotional purpose. During the 15th century the troupe split into separate groups of musicians and actors. While employed as household servants and expected to perform for their master at calendar festivals, they were allowed to travel, taking their costumes and stage properties with them, and to perform for reward wherever their

Christian saints and martyrs grew up simultaneously throughout Christendom but of a more markedly national character, as determined by the particular story.

Additional room for topical and local subject matter was provided by the dramatic adaptation of sermons depicting mankind's struggle to arrive at doomsday with an army of virtues rather than vices to plead his fate. This kind of play, religious in purpose but secular in virtually all externals, linked parable and symbolism in dramatic narrative to the symbolic manner of presentation derived from the liturgical music plays.

Thus the way was opened in every European country for a theatre as secular as that of antiquity but now consistently Christian in its ethos. In France the result was seen in *entremets* and *farces*; in Germany in the *Fastnachtsspiel* and (farther east) in the *Neidhartspiel*; in Spain the *sanete*; in England in the "dissolving" (formerly mumming, latterly masque) and the interlude (see INTERLUDES; MASQUE; MUMMERS). All of these genres are distinct, national, independent; yet at the same time each of them is only an aspect, coloured by racial temperament, geography and climate, of a spirit common to Christendom. These factors also governed the conditions of performance, common practice being more noticeable than particular variants. Performances were

leader could obtain entree. Weddings and other private celebrations provided the occasions for such performances. The plays, compared with those of the religious stage, were short and often the work of a poet of reputation. Masks were frequently used and doubling of parts was invariable.

This association with aristocratic traditions and requirements brought the nascent theatre of social recreation into close contact with the codes for identifying person, rank and place developed in heraldry. Royal progresses, coronations, tournaments and battle honours which were usually celebrated by elaborate civic pageantry, provided a meeting point where the emblematic conventions of heraldry and of Christian ritual could be fused to the advantage of the actors and the painters and engineers who embellished their stages. The characters of the pageant theatres of city streets, in their persons and their speeches, contributed to a similar amalgamation of scriptural, mythological and historical figures.

This was the theatre—religious in its inception, recreational in its later development—that in the 16th century joined hands with the theatrical traditions of Greece and Rome; this was the theatre that was destined by its associations with Roman Catholic faith and ritual to become a principal target for Protestant reformers.

### 3. Renaissance, Reformation and Counter-Reformation.

—The revival of interest in all things Greek and Roman, hastened by the fall of Constantinople to the Turks (1453) and the invention of printing, affected every theatre in Europe either directly or indirectly through Italian example. At first there was the novelty of seeing in action plays that had not been performed for more than 1,000 years; then there was the attempt to recreate something of the conditions and atmosphere of the original performances in Roman or Greek times; finally there was the adaptation of both to fit changes in manners, language and technical skills: the appeal of "modern dress" performances. Plautus' *Menaechmi* was performed in Latin before Duke Ercole d'Este in 1486, and Terence's *Phormio* by St. Paul's choirboys before Cardinal Wolsey at Hampton court in 1528. The reliance of Latin comedy upon typed characters (master, parasite, young lovers, braggart-coward, etc.) and upon plots of intrigue and situation made it easy for 16th-century adapters to do much the same in both vernacular speech and contemporary idiom. Cardinal Bernardo da Bibbiena's *La Calandria* in Italy, Rodrigo Cota's *Celestina* in Spain and Nicholas Udall's *Ralph Roister Doister* (c. 1553) in England are examples of this adaptation. In tragedy, a similar reliance upon Latin example (Senecan closet drama) and upon Latin adaptations of Aristotle (rather than the Greek original) provided Renaissance revivalists with a picture of ancient drama in which questions of form assumed a greater importance than those of either content or purpose. Dramatic entertainments of this kind, eagerly championed by pedantic scholars and deemed by their patrons to be a proper adornment of a civilized household, were accepted by the intelligentsia of Europe regardless of whether or not they were likely to enjoy any popular support.

Had the divorce between the religious stage and the theatre of pedagogic archaism been as complete in other European countries as it was in Italy (where the latter was largely pioneered), there would have been no "golden age" of Lope de Vega, Cervantes or Calderón in Spain and no "Elizabethan theatre" in England, for both English and Spanish theatres depended for their existence on the triumph of popular common sense over academic rationalism and an extravagant addiction to spectacle for its own sake.

In Italy, *commedia erudita*, comedy and tragedy imitating Roman example, was played out within 100 years and became subject to violent reactions in wholly unexpected directions: the beginning of *commedia dell'arte* and pastoral-lyric drama, or "opera." The former was a revulsion against a restricting form and a reassertion of the spirit of comedy stemming from that peasant stock whose religious stage had been so rudely spurned in the late 15th century. Some of the outward farcical qualities of the *commedia erudita* were taken over (e.g., scenarios, type characters), but with the *commedia dell'arte* (i.e., of the profession) the change is evident enough; improvisation was substituted for a fully scripted text, the personality and skill of the actor were now

highlighted rather than the toil and erudition of the author, and the appeal to a popular audience was restored. Tragedy of the Senecan kind (e.g., Gian Giorgio Trissino's *Sofonisba*, written about 1515 and first performed in 1562) was redeemed from suffocating boredom by the *intermezzi*, or interludes, between the five formal acts; these were devoted to songs and dances with decors designed by architect-painters of outstanding genius; e.g., Mantegna, Baldassare Peruzzi, Raphael, Leonardo da Vinci. These *intermezzi* naturally grew in length and scale to a point where they came to eclipse the more serious episodes of the performance. The "satyr" play of Greco-Roman drama provided a classical source for the *intermezzi*, with their songs, dances and scenic experiments, which were deemed, in the absence of evidence, to have developed along pastoral lines from them. Torquato Tasso's *Aminta* (1573) and Giovanni Battista Guarini's *Il Pastor fido* (1595) forged the link. In Italy itself the emphasis on song resulted in what is now called opera; in France, dance took precedence, thus opening the way to what was later known as ballet; and in England, words, song, dance and spectacle were developed in the perfect equipoise of the Stuart masque—a genre that relied too greatly on the occasion celebrated to survive without an autocratically administered exchequer.

The scenic theatre, based on heavily subsidized study of Vitruvius and later on the commentaries on him (Sebastiano Serlio, Andrea Palladio, Vincenzo Scamozzi, and Lorenzin Sabbatini were the most influential), spread during the 17th century to France, Austria, Germany, Scandinavia and also to Spain at the hands of Italian exponents imported for the purpose. Inigo Jones's reputation in English theatrical history, however, rests on his independent development of ideas picked up during periods of study in Italy (1603–04 and 1611–13). The new Renaissance theatre modified the classical theatre construction; the built-in perspective, though still formal, made an attempt at verisimilitude that led to a fundamental disharmony in the elements of presentation. The best seats in the theatre were now determined by their view of the scene. The *frons scaena* was remodeled to form a proscenium arch concealing the elaborate scenic devices behind it, though it was still regarded as part of the scenery backing the actors rather than as a barrier dividing them from their audience. It was symptomatic of this theatre that the architect-painter took precedence, at least in respect of production costs, over both dramatist and actor.

That this prototype of Italian origin was not followed either simultaneously in time or uniformly in pattern elsewhere in Christendom was because of a combination of individual national factors and the varying international pressures of the Reformation and Counter-Reformation.

During the Reformation it was inevitable that hostility to Catholic Rome and what it stood for on the one hand and enthusiasm for imperial Rome and what that represented on the other should collide at many points, not least in the theatre. In Germany, England and parts of the Low Countries and of France, Rome was at once the throne of the muses and the seat of Antichrist, the viewpoint depending on religious persuasion and academic background. With religious drama already deeply entrenched in popular esteem the theatre in these countries, however involuntarily, could not avoid becoming a contentious issue in domestic politics. In Germany the stage was set to work early in the 16th century as an active instrument of propaganda for the Reformed church. This initiative passed quickly to England—Thomas Kirchmayer's *Pammachius* (1538) was dedicated to Archbishop Cranmer—while Thomas Cromwell employed John Bale and others to write polemical interludes mocking the traditions of the Roman Catholic religious stage: the pope, monks, friars and transubstantiation. The plays were adapted from the traditional miracles and moralities and quickly led to riots. Ket's rebellion of 1549 was deemed to have grown out of a disturbance at a play in the Norfolk village of Wymondham. Tudor governments, Protestant and Roman Catholic, from 1543 onward were forced into taking legislative action against the theatre. Actors were systematically placed under strict supervision and control; an increasingly vigorous censorship was imposed on play texts in manu-

script and in print; places of performance were scrutinized and made subject to licence. Under Elizabeth I the amateur religious stage was systematically suppressed, the last miracle play to be performed being that at Coventry in 1584. Under James I all actors, plays and theatres were made subject to royal licence.

In 16th-century England neoclassical drama was not accepted unquestioningly, partly because of its association with Rome and with Latin, partly because topical debate proved far more acceptable than intrigue to audiences, and partly because the nation as a whole was thrown back on its own wits and resources in the face of the mounting threat of foreign invasion. Relaxation of tension followed swiftly upon the execution of Mary, queen of Scots (1587) and the defeat of the Spanish Armada (1588), and with it came a readmission of Italian ideas in art and education. By then, however, a distinctly English style of secular theatre had grown out of the ashes of the religious stage. It was distinguished by its reliance on the symbolism derived from liturgical plays and from heraldry; it owed its narrative to the miracle cycles and saint plays, its emphasis on debate and parable to the morality play and its professional character to the players of interludes. The shape and size of its stages and auditoriums were influenced by the animal-baiting arenas, the circular and rectangular tilting yards, the square or rectangular halls and (probably) yards of inns and by the rectangular town halls and guildhalls of provincial towns. Professionally organized and relying on the financial support of commercial speculators and the protection of sovereign and court officials, the theatre of Marlowe, Kyd, Shakespeare, Jonson, Dekker and Webster remained a popular theatre in touch with its medieval heritage and self-confident enough to draw what it wanted from neoclassical precept and no more. Public theatres (Globe, Swan, Fortune, Hope, Red Bull, etc.), private theatres (Blackfriars, Whitefriars, the Cockpit) and the court theatre of the masque represent accurately enough a box-office dependence on plays and performances reflecting past traditions, present experiments and a prototype for the future.

Where the court masques were largely the pride of amateur participants, the public and private theatres, in the hands of such shrewd and wealthy men of business as the Burbages (James c. 1531-97, Richard c. 1567-1619, Cuthbert 1566-1636), Philip Henslowe (c. 1550-1616) and his actor son-in-law Edward Alleyn (1566-1626), were in all respects professional. This distinction they achieved in the face of tough opposition from the more Calvinistically minded reformers and capitalist merchants who objected to the absenteeism created by the popularity of stage performances. These factions in society grew steadily more powerful in Jacobean and Caroline times, banning actors from one provincial city after another; the actors themselves, in concentrating upon a metropolitan business, position at court, coterie audiences and extravagant spectacle, aided their enemies in cutting the bonds of popular support. The closing of the theatres in 1642 at the outbreak of the English Civil War represented as much a popular revulsion against actors and plays, considered to be little more than royal slaves and royal toys, as it did an act of puritan retribution against a relic of popery.

In Germany, France and Spain features of this pattern are repeated but with important differences of emphasis. In Germany the initiative that adapted the traditions of the religious stage for purposes of Protestant propaganda was strong enough to retard the development of the neoclassical theatre even longer than in England. Little direct Italian influence is to be seen in German plays or stagecraft (beyond the arbitrary act and scene divisions) until late in the 16th century. The only outstanding theatrical figure was Hans Sachs (1494-1576), who adapted a disused Catholic church (the Marthakirche) in Nürnberg in 1550 as a theatre for his own and other plays acted by a company of which he was himself the leader. English traveling actors, by importing Elizabethan plays and stage conventions, gave the Germans a taste of theatre that was professionally organized for purposes of social recreation rather than for those of moral improvement and reinforced their native traditions. But this vitality was counterbalanced by the social upheaval of the Thirty Years' War, and the sterility of the polemical *commedia erudita* of the Jesuit Counter-

Reformation. Of attempts to combine popular Protestant drama with neoclassical precepts only the plays of Andreas Gryphius (1616-64) have attracted attention from posterity. Italian opera with accompanying scenery made heavy inroads in court circles, serving to establish a complete divorce between popular tradition and aristocratic taste by the middle of the 17th century.

In Spain, by marked contrast, the impact of the Reformation and Counter Reformation on the theatre was slight. The reason was that the Inquisition, as reorganized under Torquemada (c. 1486), had taken care to purge the religious stage of those elements that in other countries laid it open to ridicule. Neoclassical theatrical ideas thus developed alongside traditional popular plays and stage convention, since authors were able to write for either as inclination and occasion suggested. Since the feast of Corpus Christi continued to be observed (it was abolished in England) plays associated with the feast (*autos sacramentales*) continued to be presented throughout the 16th century and after. Courtly actor-playmakers similarly had opportunities of a far less inhibited kind than in England, although less highly organized than in Italy, to refine their craftsmanship by conscious imitation of Latin authors and to develop subject matter of an avowedly secular kind. The playwrights Juan del Encina (1468-1529) and Gil Vicente (c. 1465-1536) and the critic and theorist Bartolomé de Torres Naharro (1480-1530) provided between them the backbone of this alternative to the popular (and largely amateur) religious stage.

From this cult of *entremeses*, *comedias* and *tragedias* the Spanish theatre acquired as recognizably professional an outlook and status as that of the English interludes, while from the popular religious stage it retained as distinctly rhetorical and emblematic techniques of performance and presentation as those of the Elizabethan theatre. Market places and innyards on provincial circuits provided the actor-playwright Lope de Rueda (1510?-65) with his theatre building and it was a member of his company, A. de Rojas, who in *El Viaje entretenido* gave a vivid picture of the actor's life. Under municipal control professional theatres were provided in *corrales* (courtyards) administered by religious and charitable institutions. These buildings slightly precede in date those in England, but whereas in England such buildings were limited to London, in Spain the practice spread quickly from Madrid (c. 1560) to all large provincial cities. As in England, the performers suggested improvements in the buildings they used and these found their way into subsequent designs. Performances took place in the afternoons and were accompanied by items of song and dance corresponding to the Elizabethan jig. A roof projected over a raised stage; the wall from which the stage jutted contained doors and windows; costume was contemporary dress adorned with heraldic or other emblems of identification; traps and flying machines were provided. This theatre was nearly akin in national temperament and professional need to that of Elizabethan and Jacobean England, and it produced dramatists of as outstanding a quality in Cervantes, Lope de Vega and Calderón, all of whom exploited the narrative possibilities of their stage to the full. Action, wide-ranging and fast-moving, was the hallmark of this theatre, just as it was of the English theatre. It differed from English practice, however, in the continuing liberty allowed to plays based on biblical and theological subject matter; in the work of Calderón, for example, there is to be found a perfect blend of religious subject matter and symbolic presentation: the medieval theatrical tradition has been modernized in theology and literary style by the Counter-Reformation and in stage convention by the adaptation of neoclassical settings and machinery that was wholly lacking in England. Where England contributed to the German theatre through the repertoire of strolling players, Spain contributed to France the vitality of its drama of character, situation and intrigue.

Spanish influence, however, was particularly marked in the Low Countries, governed by Spanish rulers through the first half of the 16th century and in revolt against them during the second half. The indigenous religious stage, with its notable morality play *Elckerlyc* (*Everyman*, c. 1470) and the festivals of the *Rederijkers Kamers* (chambers of rhetoric; see DUTCH LITERA-

ture), formed the basis of a theatre that might have been as influential throughout Europe as Flemish painting had not conditions of political and social unrest disrupted its development and made it subject in turn to the dominance of Spanish, Jewish and French influence. The Schouwburg theatre, built in Amsterdam by Jacob van Campen (1637), nevertheless provides the theatre historian with as interesting a building as the Teatro Olimpico at Vicenza (Palladio and Scamozzi, 1580-84).

Both illustrate the transition from medieval to classical styles of theatre architecture; the Olimpico, as markedly advanced toward the new style as was the Schouwburg (although built so much earlier in time), is noticeably dependent on the past. In these two theatres and in Johannes de Witt's drawing of the Swan theatre in London (built c. 1594) may be seen three manifestations of neo-classicism tempered by the pressures of the Reformation and Counter-Reformation that conveniently epitomize a whole period of violent controversy and astonishingly varied achievement.

### C. CLASSICAL, BAROQUE AND ROMANTIC REACTION

The French theatre followed Italian example in divorcing religious and popular drama from secular and recondite drama. Sacred drama was forbidden by decree in 1548 to prevent its being used by the Protestants to try to bring Roman Catholicism into contempt. Artists, unfortunately, cannot be created by decree and in consequence the great French heritage of religious plays and popular farces was followed by attempts to ape Italian academic example, but in a manner even more dogmatic than the model. The typical medieval mixture of joyous and sad, tragic and comic found no sequel in the rigid theorizing of the scholar poets, of whom Étienne Jodelle (1532-73), Robert Garnier (c. 1545-90) and Jacques Grévin (1538-70) enjoyed a limited repute at the time. A taste for dancing and spectacle grew up among court amateurs in France; this centred on the court ballet, of which *Le Ballet comique de la reine* of Balthazar de Beaujoyeulx (Baldassarino de Belgiojoso) is the best-known example. Printed in 1582, it provides illustrations of the scenic arrangements that were still traditional and include Circe's garden, a grove of trees and a large cloud. Early in the 17th century Pierre Corneille encountered bitter criticism in trying to bridge this gap between the unity of

place demanded by the theorists and the *décor simultané* of theatre practice, a gap only made the wider by the conspicuous absence until 1595 of any professional acting company other than the crippled Confrérie de la Passion, which owned the Hôtel de Bourgogne.

Not until political stability returned to France under Cardinal Richelieu could a theatre as genuinely professional as that of Spain or England return to Paris. Two theatres, the Hôtel de Bourgogne and the Marais, then began to develop on professional lines and in keen competition, with tragedy, comedy and pastoral in the Italian manner established as the only recognized dramatic genres. It was not until 1650, however, that Italian stage machinery was coupled to performances in public theatres: the occasion was Corneille's *Andromède* with settings by Giacomo Torelli. It was left to Molière and Racine to bring the French theatre, one in comedy the other in tragedy, to a pre-eminence sufficient to eclipse that of both England and Spain, and this despite perhaps the most vicious sequence of literary intrigues and personal attacks the theatre has ever known, or at any rate recorded. Molière (1622-73), himself an actor, and Racine (1639-99), acquainted from youth with theatre practice and assisted by Molière, enjoyed that same protection of the sovereign and those near to him that had distinguished the careers of Shakespeare, Ben Jonson, Philip Massinger and others in England; together they brought to the theatre a degree of observation both of human foibles and of human passion and suffering that sufficed to give a genuine vitality to the revived classical forms not attained before or since. Aided by two remarkable musicians, Jean Baptiste Lully and Jean Philippe Rameau, the pastoral form was also vigorously developed in France in the directions both of opera and of ballet.

The influence of Molière and Racine, together with that of Corneille, was felt everywhere in Europe and was synthesized for Europe in Boileau-Despréaux's *L'Art poétique* (1674). Nowhere else, however, was their genius matched; only in England, and there only in comedy, was anything written or staged that has maintained a hold on posterity in terms of frequent adaptation and revival. English tragedy modeled on the French, of which Sir William Davenant and John Dryden were the twin advocates, degenerated, as Italian tragedy had done, into operatic fantasy. Everywhere, however, from Sweden in the north to Austria in the

east the real victor was the theatricality of the baroque spirit expressed in stage settings and their illumination. Classicism triumphed momentarily in France, but it was the spectacular rather than the literary quality of the revival that held Europe entranced throughout the 18th century. Everywhere it was the designers and the actors whose names counted with audiences rather than those of the writers. The costume designs of Lodovico Burnacini (1636-1707), the perspective settings of the Bibiena family, which between 1680 and 1780 were unchallenged for originality and activity, and theatres like the opera house in Bayreuth define the baroque spirit and its rococo sequel that spread outward from dramatic representations to enhance the whole of aristocratic life. Theatre worthy of the name became a courtly or at least a metropolitan toy designed to kill time in a manner as costly as befitted its aristocratic patrons. Popular theatre dwindled into fairground improvisations and the meagre, eviscerated reper-

of strolling players. At both levels there were extensive exchanges, Gustavus III of Sweden enjoying at Drottningholm in 1780 what Louis XIV had initiated at Versailles a century earlier, Pierre de Chamblain de Marivaux in Paris enjoying closer affinities with Carlo Goldoni in Venice or Richard Brinsley Sheridan in London than with Molière, and booth theatres in provincial streets holding audiences with debased relics of Jonsonian "humour," German farce and Spanish intrigue grafted onto the improvised scenarios of *commedia dell'arte*.

Reaction and revolution came not from left or right but from the centre; i.e., from the bourgeois public denied a theatre for so long by Puritan sentiment in England, by aristocratic privilege in France, by war and social unrest in the Low Countries and mid-Europe, by stagnation in Spain and by feudalism in Russia and Scandinavia. A spirit of satire and sentimentality, long smoldering beneath the surface, began to make itself felt in England, particularly in the work of Henry Fielding and George Lillo; similar romantic yearnings in Germany were made vocal by Lessing and in the following century, these tendencies were further advanced by the nationalistic and democratic fervour of Italians, Norwegians and Russians, culminating in the work of Verdi, Ibsen and Chekhov. Moreover, the political revolution that, country by country, shattered the aristocratic façade of European theatre was accompanied by an industrial revolution of equal consequence to stage architecture and convention.

The pastoral fantasies, countertenors, literary controversies about the unities and restricted admission by privilege of birth were of little or no interest to the merchant *bourgeoisie* of Europe returning slowly to theatre or demanding theatres of their own. They wished for action and narrative of a kind not seen on the stage (outside Spain) for generations; an unwitting return was made to the genuine beginnings of theatre in ancient Athens or during the middle ages rather than to those beginnings mistakenly judged to be represented by the Roman stage on which the whole edifice of neoclassicism had been built. These yearnings, however, were not supported by any particular erudition and were in any case quickly coloured with political vested interest and spectacular possibilities of the new stage devices. Aristocratic opera and ballet were thus subjected in the early 19th century to popular sentimentalizing, comedy of character, manners and wit; to a taste for farce and tragedy; to an eagerness for violence and horror.

The cult of spectacle, however, so long a luxury for the new and the corrupter of their theatre, did not disappear; it increased and corrupted in turn the taste of the newcomers. The apotheosis of the changed theatrical style was melodrama.

Melodrama is a difficult term to define since it embraced among writers such distinguished men as Goethe, Victor Hugo and Pushkin reached its zenith in Germany and its nadir in England and the United States and, having quitted the animate theatre via grand opera and classical ballet, has perpetuated itself in motion picture and in television serial. In one sense it represents the last despairing heroic fling of the theatrical rhetoric inherited from a pre-Christian past; in another sense it has come to stand for all that is most sentimentalized and hypocritical in a Christian-rooted theatre. What is clear is that melodrama represents a watershed in the history of European theatre: it was at once the last genuinely theatrical form with an appeal strong enough to draw its support from all ranks of society and the jumping-off point for that division between the actor and his stage that characterized the subsequent development of dramatic art in the west. Some actors, singers and dancers chose to exploit the more hedonistic and less educated element of the popular audience. With methods and organization resembling that of the medieval minstrel troupes or Roman mimes, they made what capital they could from their own personality and special "acts" but with the important difference that on the financial success of performances in public houses it became possible to erect theatres for the purpose, thus giving a degree of urban regularity to what had hitherto been the largely rural and nomadic occupations of the fairground. From the "music room" annex to public bars sprang not only the professional circus but also the great provincial and metropolitan chains of theatres known in Britain as music hall and in the United States and parts of Europe

as vaudeville and epitomized in England by the twice-nightly variety shows managed by Sir Edward Moss and Sir Oswald Stoll (see below; see also CIRCUS; MUSIC HALL AND VARIETY; VAUDEVILLE).

Where stage plays were concerned, the popular section of the audience derived amusement from parodies of classical theatre forms (burlesque [*q.v.*]; extravaganza; burletta) and from the spectacular sensations of shipwreck, forest fire and earthquake intermingled with violence and idealism supplied in the more elaborate melodramas, of which Guilbert de Pixérécourt in France (1773–1844) was the pioneer and prime exponent. A similar cult of individual personality developed within the more orthodox dramatic genres of the traditional theatre, finding its prime expression in productions of Shakespeare's plays in England, in opera under German and Italian leadership and in Russian ballet. Shakespearean title roles gave the "star" actor his pre-eminence in his profession, while vocal virtuosity and powers of mimetic expression were similarly emphasized in opera and ballet, respectively. Paradoxically, the narrative and spectacular elements of libretto and setting were also exploited for their own sake in a manner that made all actors other than the star the virtual prisoners of an army of technicians. The invention of gas lighting with the possibility of blacking out the auditorium (*c.* 1823), subsequently improved in both safety and flexibility by electric lighting, forced even the star actor off his commanding "forestage" and incorporated him within the stage picture as an adjustable item in the pictorial design. Because of the technical problems involved in manipulating these animated landscapes with narrative coherence, the star actor was gradually obliged to hand over his control of his fellow actors and the scenery; both actors and scenery were now subject to control by financial speculators and a neutral observer who, from the humble status of stage manager, came thus to be elevated to the dignity of producer, *régisseur* or director. Further dignity and power were added to his status as techniques of mechanical reproduction in motion pictures, radio and television increased the ratio of engineers and technicians to actors in any single dramatic performance, and as the star actors lost financial control to their managerial partners. The latter situation was somewhat modified in the 1950s when some Hollywood stars began producing their own films.

With the retirement of the actor off his forestage and into the scenic picture, realism of an almost photographic kind became a main object of production. Assisted by a developing interest in historical and archaeological accuracy that was initiated by the actor David Garrick (1717–79) in his costuming of Shakespeare's plays and was brought to its highest point by Sir Henry Irving (1838–1905) and Sir Herbert Beerbohm Tree (1853–1917) in the costumes and settings used in their productions, this realism in externals demanded concessions from both dramatists and actors. Both the written and the spoken text had to be scaled down if the dichotomy between realistic sets and costumes and a rhetorical text and delivery were not to appear ludicrous. The language of poetry and a large measure of the virtuosity that had earlier distinguished the professional from the amateur actor were both victims of this sacrifice. Dramatists were forthcoming in France in Victorien Sardou and Augustin Eugène Scribe, in England in Thomas Robertson, in Germany in Gerhart Hauptmann, in Scandinavia in Bjørnstjerne Bjørnson, Strindberg and Ibsen and above all in Russia in Chekhov, capable of making stage action and dialogue look and sound as natural as everyday life. It was in Russia at the Moscow Art Theatre that the first serious steps were taken by the actor-producer Konstantin Stanislavski to codify a style of acting as appropriate or "natural" as the verisimilitude of the new plots, settings and dialogue demanded. The imitations that followed, under George Bernard Shaw and Harley Granville-Barker in England, under André Antoine and Jacques Copeau in France and under Eugene O'Neill, Lee Simonson and others in the United States, together with the reaction against them, belong to the 20th century and to modern drama and theatre.

#### D. SUPPLEMENTARY ARTS

1. **Opera.**—Opera (*q.v.*) deserves consideration as a form of theatre in which song and instrumental accompaniment are pre-

dominant. Much eastern theatre is operatic in that the dialogue is musical; so too was the liturgical drama of the medieval church.

Opera of the sort, however, that is generally accepted under that name was introduced into Europe by the group of Florentine patricians known as the *Camerata* (c. 1580), whose object was to intone the dialogue of tragedy in the manner they imagined it had been recited in the theatres of ancient Greece. The result was what is known as recitative, which, when linked to aria (song), provided a libretto (text) sung throughout to musical accompaniment. The story of *Orpheus and Eurydice* was provided with such settings by J. Peri, G. Caccini and C. Monteverdi in quick succession between 1600 and 1607. The latter did for music-tragedy what the painters of equal genius had done 50 years earlier for the tragic scene. Opera, thus firmly based on scenery, song and tragic or pastoral themes, swept northward through Venice, where the first public opera house was opened in 1637, to Vienna and Germany. Then it swung in two great arcs northeast to Warsaw, Stockholm and St. Petersburg and northwest to Copenhagen, Amsterdam, Brussels and London at the turn of the 17th century into the 18th century. Paris and London enjoyed a brief creative period of indigenous opera in the Italian manner between 1650 and 1700 dominated respectively by Jean Baptiste Lully and Henry Purcell.

Comic themes were introduced from Naples early in the 18th century, being developed from between-the-acts of serious opera in the same way that tragic and pastoral opera had itself developed out of the intermezzi to neoclassical tragedy. While Handel and Gluck dominated the serious operatic scene during the early and middle parts of the 18th century respectively, these developments reached their peak in Mozart's compositions for the theatre toward the close of the century.

The coincidence of political and industrial revolutions with the bourgeois sentimentalism evident in melodrama brought about a reaction toward romantic and historical plots; together with the development of the orchestra these factors led directly to the romantic opera of Verdi (1813-1901) and Wagner (1813-83). The outstanding theatrical features of all 19th-century operas are the emphasis placed on melodic line and the reliance upon the vocal range and power of the principal singers. These characteristics were quite out of line with developments in the regular theatre, as signaled in the plays of Ibsen, who abandoned verse for prose, and in the acting style of the Moscow Art Theatre under Stanislavski.

Reaction to the primarily tragic and serious effusions of Verdi and Wagner (grand opera) found its outlet in light, or comic, opera. In England the light opera of W. S. Gilbert and Arthur Sullivan, in Austria the waltz opera of Johann Strauss and Franz Lehar and in France the *opéra-bouffe* of J. Offenbach (where recitative was reduced to the barest minimum and unaccompanied prose dialogue restored) opened the way to the operetta and musical comedy (q.v.) of the 20th century and perhaps the first distinctively transatlantic form, the American "musical."

**2. Ballet.**—A ballad, or ballet, in the 15th century formed an item in the repertoire of the minstrel troupe that came to be enacted in mime; to this were added the embellishments of songs and dances, the whole making up an evening's revels. During the 16th century the poem became little more than a prologue to establish the nature of the dances in masquerade. These developed as a series of "entries" of disguised courtiers who, after dancing with one another, took partners from among the spectators. Known in Italy as *maschera*, in England as masque and in France as *masquerade*, the element of dance became predominant in France during the 17th century. These ballets danced by amateurs reached their climax at Versailles at the hands of Lully and Molière. After being taken over by professional dancers they were integrated with Italian opera but could not develop further until fashion in dancers' costume allowed both greater freedom and precision of movement. This change, initiated by Marie Camargo (1710-70), was followed by attempts to link formal dances with musically accompanied mime in the same way that one aria was linked to another by recitative in opera. The innovator was J. G. Noverre (1727-1810), whose treatise *Lettres sur la danse et sur les ballets* stim-

ulated public interest and discussion of ballet as an art form all over Europe.

The objective was a re-creation of the sort of dancing deemed to have graced the classical theatre of antiquity; but, being pursued at a time when romantic forms were beginning to find public favour at the expense of classical ones, ballet derived little more from pseudoclassicism than the conventional ballerina's costume of skintights surmounted by a short skirt of tiered muslin and the so-called "classical" dance figures before being enveloped in the mystical miasmas of fantasy and spectacle derived from Gothic melodrama. Nevertheless the combination of costume and dance figures sufficed to re-establish the bodily skill, grace and expressiveness of the actor with force enough to attract to it the unsophisticated folk dances of peasant communities who as yet had no other theatre. The imperial ballet of the Russian court was in the most advantageous position for this assimilation: for in Russia, as a comparatively undeveloped country of great geographical and climatic variety, a wider range of peasant dances existed for exploitation than anywhere else in Europe. A rapidly developing and strongly nationalistic school of music, itself largely indebted to the melodies and rhythms of folk music, provided Russian ballet with creative impetus enough not only to surmount any danger of the new art's dying as a result of suffocation from repetition and stereotyped convention but also to revivify dancing in the west. (See BALLETS.)

**3. Mime, Pantomime, Vaudeville and Music Hall.**—Any concept of a theatre other than that restricted to timber, bricks and mortar depends for its existence on and develops around the person of the actor. Moreover, any society that has once advanced far enough to recognize the pleasure latent within the performer-beholder relationship has never been able to dispense with it. Thus although the peoples of the world have, from time to time and from place to place, and for various reasons, either refused to permit or failed to sustain an organized theatre, they have never lost touch with the mimer who is able to entertain with no properties other than his own voice and person. Recognizing the tenuous nature of his hold over his audience, the mimer has inevitably and invariably relied upon the easiest means of provoking laughter—verbal mockery and physical indignity.

Whatever society has prescribed to be sacred or illicit has tempted comment from him by virtue of the power that any shock possesses to attract and hold attention. The barbed satire of social criticism and the appeal of pathos, both demanding a high degree of awareness and intelligence in their portrayal, augment the equipment of the more skilful and experienced mimer.

Throughout recorded history therefore the mimer, whether known under Greek, Latin or vernacular names, has enjoyed the abiding favour of the more oppressed sections of society and the constant disapproval of those in authority, except at rare times when that authority was too secure for any challenge to be regarded as a threat. Markets, fairgrounds, city streets at festival times, village green and taverns have provided their perennial auditoriums. At times they have organized membership, their finances and their patrons well enough to originate a distinctive style of theatrical performance warranting a label. The Atellan fairs of Roman Italy, the medieval minstrel troupe, the Feast of Fools, the *commedia dell'arte* of Renaissance Europe, harlequinades, English pantomime and music hall, extravaganza, burlesque, revue, cabaret, American vaudeville and American burlesque (including strip tease) are among the most notable forms. All have been characterized by the lack of any regular script, the liberty permitted to the actors to improvise their actions and extemporize their dialogue as prompted by audience response; by the occasional interpolation of song and dance; by solo performances from individual artists; and by the exploitation of spectacle for its own sake in conjuring tricks, sexual allure, scenic machinery and, in the case of pantomime, music hall and vaudeville, in luxury and glitter of the auditorium. Blasphemy, obscenity and sensationalism, if not invariable characteristics, have been near enough neighbours to provoke constant reproof from councilors of church and state of actors engaged in these activities. Bourgeois opinion has generally aligned itself behind these dignitaries when faced with a choice

occupation the Progressive Theatre returned to its original policy, producing a number of Russian plays, and Hijikata returned to Japan. By the 1960s the Japanese theatre had outgrown its Communist beginnings, although a great many of its plays dealt with social problems. The variety of Western plays given was proof of its tolerance and interest in conflicting ideas.

**India.**—The diversity of 20th-century Indian theatre was exemplified by the annual drama festival in New Delhi, started in 1954, at which some 15 languages and cultures were represented. The most influential theatre was the Prithvi, because it played in Hindi, the national language, and thus reached a far larger audience than, for instance, the Bengali and Marathi theatres. The Prithvi Theatre was founded in 1943 by Kapoor Prithviraj, famous throughout India as a film star. Its tours extended from Calcutta in the east to Saurashtra in the west, from Kashmir in the north to Dhanushkodi Rameswaram in the south. The plays in its repertoire dealt mainly with contemporary life and reflected Prithviraj's political and religious views. Most of the comparatively small amount of professional acting was concentrated in Calcutta, which had a number of modern theatres and a prosperous motion-picture industry; thus, actors were able to work in both mediums. Theatre Unit, Bombay, India's most modern-minded theatre, was founded in the mid-1940s by Alkazi, a young actor and director trained in London at the Royal Academy of Dramatic Art. The company performed in English but was essentially an Indian theatre catering for an Indian public. An instance of the combining of the traditional folk and dance drama (see DANCE) with modern theatre was Sundari's Gujarati Theatre, with headquarters in Bombay. The plays dealt with political and social themes and particularly with women's emancipation. In south India the first modern theatre was founded in the early 1930s by Ephrahim Rajamanickam. Choice of plays was strongly influenced by his deep religious convictions. Besides playing in its own theatre in Madras, the company, more than a hundred strong in the 1960s, toured widely, visiting other provinces to play to Tamil communities. The Indian National Theatre, Bombay, founded in the 1950s as a workers' theatre to take the drama to farms and factories, by the 1960s had branches in all the big cities. The actors were mostly amateur.

**Other Countries.**—Outside India, Japan, and China, there was hardly any modern theatre in Asia. In countries such as Ceylon, Burma, Malaya, and Indonesia, the highly developed forms of dance drama (see DANCE) were so popular that there was little urge to found a modern theatre. Only in the Philippine Islands were there signs of a modern theatre developing from the efforts of enthusiastic amateur groups such as the Philippines National Theatre and the Manila Theatre Guild.

**2. Great Britain.**—*Direction and Development.*—During the 19th century the theatre was ruled by actor-managers who directed their own productions with their permanent companies, playing the leading parts themselves. At the beginning of the 20th century their authority began to be challenged by new, independent directors who rarely acted in their own productions. The first to establish himself was Dion Boucicault (1859–1929), who from 1901 to 1915 directed all plays at the Duke of York's Theatre, London. An autocratic director, he acted all the parts to the cast, who had to copy him to the minutest detail. A director with a different method was Harley Granville-Barker (q.v.), who from 1904 to 1907, in partnership with J. E. Vedrenne directed a series of short runs at the Royal Court Theatre, Chelsea, London; he opposed the artificial style of acting of the period. At first he was accused of teaching his actors "not to act" because he trained them to behave as normal human beings; to create a part by identifying themselves so completely with the character that gesture, movement, and facial expression were a natural expression of that character's thoughts and feelings. At a time when most actors had no hesitation in sacrificing character for flamboyant theatrical effect, Granville-Barker laboured to make the characters in a play "seem to live and move by the laws of their own being." He gathered round him a group of new writers hitherto uninterested in writing for the theatre because of its artificiality. He was at his best as a director with the plays of

Gerhart Hauptmann, Ibsen, and Galsworthy.

Granville-Barker did not only direct naturalistic plays; his Shakespearean productions at the Savoy (1912–14) revolutionized Shakespearean theatre in England. As a young man he had acted in William Poel's productions for the Elizabethan Stage Society (see ACTING, DIRECTION AND PRODUCTION: *Acting*), and had learned how much a Shakespeare play depends for its full effect on unbroken continuity from scene to scene. Contemporary actor-managers with their spectacular productions kept halting the play for elaborate changes of scenery: but instead of realistic scenery Granville-Barker used stylized, decorative backgrounds. He speeded up the plays by avoiding scene changes and by teaching his actors to speak the verse swiftly, though without gabbling. To those accustomed to the slow and ponderous declamation of Shakespearean actors, it seemed a breakneck speed.

In 1920 Granville-Barker virtually retired from the theatre, but the subtle and exact kind of realistic production, purged of theatrical cliché, was developed by Gerald Du Maurier (q.v.) and Basil Dean. Before World War I Dean had worked under Annie (Miss A. E. F.) Horniman (q.v.) at the Gaiety Theatre, Manchester, where she had insisted on the sort of naturalism first practised at the Royal Court (see below *Provincial and Repertory Theatre*). At the St. Martin's Theatre Dean trained a young company to give an exact interpretation of the external characteristics of their parts; though his method lacked Granville-Barker's emphasis on imaginative interpretation, the result was acting of extraordinary clarity, sharpness, and precision. As a director, Dean continued the dictatorial methods of Boucicault. Du Maurier, on the other hand, directed with a deceptive casualness, which, like his acting, concealed a highly developed naturalistic technique. Both as actor and director he had, however, an unfortunate influence on English acting, because his imitators, lacking his technical skill, only achieved underplaying and inaudibility in their attempts to emulate the quiet ease of his naturalness.

A director who refreshed English acting and direction was Theodore (Fëdor) Komisarjevski (1882–1954), who in 1919 went to England from Russia, where he had been director of the Imperial and State theatres. Under his direction of plays by Chekhov and other Russian authors the acting achieved a sensitiveness and inner realism that set a new standard in the English theatre. His Shakespearean productions at Stratford-upon-Avon startled and often infuriated audiences accustomed to conventional presentation. His productions were full of invention, sometimes brilliant, amusing, and illuminating, sometimes merely wayward. He may be blamed for starting the "let's-be-different-at-all-costs" style of Shakespearean production still all too prevalent, and exemplified in Sir Laurence Olivier's "Othello" (1965).

In the same tradition, Tyrone Guthrie (1900– ; knighted 1961), a director with a superb theatrical imagination, beginning in the 1930s at the Old Vic, London, emphasized the point of a line with a revealing stroke of "business," and brought small parts vividly to life by imaginative touches of detail, heightening the effect of everything that happened on the stage by his gift of pictorial composition and swirling movement. But sometimes his inventiveness was used merely to surprise and shock the audience or to satisfy his own sense of humour. Even after 1953, when he became director of the Shakespeare Festival, Stratford, Ont., in a theatre built to his own design, he continued to direct in London, New York, Minneapolis (1962–65), where a theatre designed by him was built, and Edinburgh. Another fine Shakespearean producer was Peter Brook (1925– ), with superb productions in the 1950s and early 1960s of *Measure for Measure*, *Titus Andronicus*, *The Winter's Tale*, and *King Lear*, the last-named for the Royal Shakespeare Company, of which he became co-director in 1962 with Peter Hall (1930– ), also an outstanding Shakespearean producer, notable for productions of *Henry VI* and *Richard III* as a trilogy, *The Wars of the Roses* (1963). Brook also directed plays by Anouilh, Sartre, and other modern dramatists. His production of the German-born Peter Weiss's *Marat/Sade* (first performed, 1964) for the Royal Shakespeare Company in London and New York in 1966, was the first of its many European productions.

In the late 1950s the most influential British director was Joan Littlewood. In 1945 she had founded a company at Manchester—Theatre Workshop—for working-class audiences, which in 1953 moved to the Theatre Royal, Stratford, in the East End of London. The productions, at first mainly of Shakespeare and other classics, with some topical plays by Ewan MacColl, folksinger and political dramatist (with whom in the 1930s she had founded the Theatre of Action), gradually became more definite in style. She encouraged audience participation; allowed actors to improvise—all her later productions were “collective” in that the actors shared in planning the presentation, often took liberties with the text—and borrowed traditions from music-hall (*q.v.*) such as impromptu asides to the audience and the introduction of topical songs and jokes. Her productions also owed much to Bertolt Brecht (*q.v.*; see also below, *Germany*) in their encouragement of audience participation, and in use of music. Her first West End transfer, in 1955, was with MacColl's version of *The Good Soldier Schweik*; and thereafter her influence was more widely diffused. *Oh What a Lovely War!* (1963), an original evocation and criticism of World War I, using music, newspaper headlines, and other devices to point its message, is perhaps her most famous production: its success in Sweden in 1965 led to an imitation, *Oh What a Lovely Peace!* (1966). Her best productions—Brendan Behan's *The Quare Fellow* (1956) and *The Hothouse* (1958), and Shelagh Delaney's *A Taste of Honey* (1958)—were full of vitality, noisy, and broadly humorous, yet with subtle characterization. In 1964 she founded a theatre school in Tunisia.

In the late 1950s and 1960s the most experimental London theatre was the Royal Court, under George Devine (1910–66), who in 1956 set up the English Stage Company. Its avowed purposes were to allow novelists to try their hand as playwrights and to introduce new writers and modern foreign drama. Its club, the English Stage Society, gave Sunday performances without decor, so allowing experimental plays to be tried out. Most of the new English playwrights of the 1950s and 1960s—John Osborne, John Arden, N. F. Simpson, Willis Hall, Ann Jellicoe, and Arnold Wesker—had their works first produced by the English Stage Company, which also gave many directors, designers, and actors later outstanding in the West End their first chance. In 1965 Devine was succeeded by William Gaskill, who continued his policy. But although several directors, trained at the Royal Court, were distinguished by brilliance and willingness to experiment, lack of a permanent company prevented development of a “Royal Court” style.

There was no permanent dramatic company in London until 1960: even the Old Vic (which, before it was bombed in 1940, was devoted to Shakespearean production), engaged actors only for one season. To remedy this lack Peter Hall engaged a company (called from 1961 the Royal Shakespeare Company), on long-term contract to play at Stratford-upon-Avon and at the Aldwych

Theatre, London, presenting modern plays as well as Shakespeare and other classics, both often produced in experimental styles. Michel Saint-Denis became co-director (with Peter Brook and Peter Hall), in 1962, and in 1966, when he and Peter Daubeny (manager of the World Theatre Season at the Aldwych, which took to England dramatic companies from Greece, Italy, France, Czechoslovakia, the U.S.S.R., Poland, Japan, Germany, and Israel, in their own plays) became consultant directors, Paul Scofield (1922– ), the company's leading actor, took his place. A permanent theatre for the company, built by the Greater London Council, to be finished in 1973 as part of the City of London's Barbican scheme, was to have an open, triangular stage.

*Provincial and Repertory Theatre.*—In the provinces, the theatre divides into touring, repertory, and amateur. The touring theatres are visited by London companies either before or after they play in London, and by companies engaged to tour a London success. A play on tour seldom remains for more than a fortnight, but a big musical production sometimes stays up to several months. At Christmas nearly all these theatres stage an elaborate pantomime (*q.v.*), so popular that the run often extends for three or four months. In the early 1920s there were more than 250 touring theatres in England and Scotland. Many towns had several, as well as at least one music hall. By 1966 the number had dwindled to little more than 20. Many had failed to survive the competition of motion pictures; others were destroyed during World War II; and after the war television proved a deadly rival.

“Repertory” theatres in the provinces withstood competition more successfully. These so-called repertory theatres had at first no right to the title, because, although they maintained permanent companies, they did not keep a repertoire of plays ready for production as do continental “repertoire” theatres, which give performances of several plays from their repertoire each week. English repertory theatres put on a play for a short continuous run: a week, or, in the bigger cities, three weeks or a month. “Weekly rep,” in which companies were always working against time, reached a high standard of acting and production, however, and gave actors an excellent training by casting leading members of the company in minor roles for a week or two when they had a major part ahead of them. But by the mid-1960s the nature of provincial repertory had changed considerably as a result of increased government grants and bigger audiences. Most theatres had replaced the giving of a play for a short run (after which the production was scrapped) by a limited form of continental “repertoire.”

The London theatre owes much to provincial repertory, both because it provides actors accustomed to taking a wide range of parts (most West End actors graduated from “weekly rep”) and because many successes were first produced by the repertory theatres.

The third branch of the provincial theatre, the amateur “little

SCENES FROM (LEFT) HARLEY GRANVILLE-BARKER'S PRODUCTION OF *TWELFTH NIGHT*, SAVOY THEATRE, LONDON, 1912. (RIGHT) COMMONWEALTH ARTS FESTIVAL PRODUCTION OF *THE ROAD*, BY THE NIGERIAN PLAYWRIGHT WOLE SOYINKA, THEATRE ROYAL, STRATFORD, 1965

theatre," also make a valuable contribution to theatrical experiment in Great Britain. Sometimes producers and technicians are professional, but actors, designers, and stagehands are amateur, and often anonymous. One of the leading provincial little theatres is the Maddermarket, Norwich, built in 1919 as the only theatre in England with an Elizabethan stage. Productions are given during one week in each month, and have ranged from all of Shakespeare's plays to Oriental drama. Others influential before and during World War II were the People's Theatre, Newcastle (founded 1911), which gave many first performances of continental and U.S. plays; the Highbury Little Theatre, Sutton Coldfield, built during the war by the company's members; and the Glasgow Citizens' Theatre, founded in 1942 by the playwright James Bridie to encourage modern Scottish dramatists.

London has long had its own repertory theatres. The Royal Court, under Granville-Barker, and again under Devine and Gaskill, was a repertory theatre (see ACTING, DIRECTION AND PRODUCTION: *Direction*). Several repertory seasons were run in London theatres in the 1900s, but the movement was active mainly outside London, except for the Old Vic and National Theatre companies (and, later, the Royal Shakespeare Company). However, in the 1930s, experimental "club theatres" were opened. The first was the Gate (1925), founded by Peter Godfrey, and directed (1934-40) by Norman Marshall. Its policy of producing unlicensed or uncommercial plays and witty reviews made it one of the most important of the prewar "club theatres," but it was destroyed by bombing in 1941. Also influential were the Mercury, Notting Hill Gate (1933), famous for producing poetic plays by T. S. Eliot, Christopher Fry, Ronald Duncan, and others; the Hampstead Theatre Club, where in 1966, a movement called "Living Theatre," or documentary theatre, was begun, and spread to other companies as the "Theatre of Fact"; the Arts and New Arts Theatre Clubs; the Unity, St. Pancras, which in 1936 declared its intention of replacing the "escapism and false ideology of the conventional theatre" with a left-wing "agitational theatre," carried out with first English productions of plays by Clifford Odets, Sean O'Casey, and Soviet dramatists. After World War II the outstanding new foundation was that by the actor and director Bernard Miles (1907- ), of the Mermaid (1951), as an Elizabethan-style theatre, first in St. John's Wood, and after 1959 in the City of London—the first new theatre in the City for 300 years. In 1966 the Jeanetta Cochrane Theatre opened, in association with the Edinburgh Traverse Theatre Club.

The first British repertory theatre was founded by Annie Horniman (q.v.) at the Gaiety Theatre, Manchester, in 1908. It introduced to England the work of a number of important continental dramatists and gave opportunities to promising playwrights, among them Alan Monkhouse, Stanley Houghton, and Harold Brighouse, who became known as "the Manchester School." In 1921 it became a cinema. The oldest existing repertory theatre is the Playhouse, Liverpool, which opened in 1911. From 1922 to 1944 it was directed by William Armstrong, who had a gift for recognizing and developing talent, so that many leading players (among them Sir Michael Redgrave) began at the Playhouse. The repertory with the most distinguished and adventurous record is the Birmingham Repertory, founded in 1913 by Barry Jackson (knighted 1925), who also founded the Malvern Festival (1929-39; revived 1947, and again in 1966), where notable first performances were given of plays by Shaw, James Bridie, J. B. Priestley, and John Drinkwater, as well as of Tudor, Jacobean, and Restoration plays. Between World Wars I and II he took many productions to London, including the first modern-dress *Hamlet* and the first production of Shaw's *Back to Methuselah* in its entirety. Among other leading provincial repertory theatres, many of them subsidized by local authorities and so-called "civic" theatres, are those at Nottingham, Bristol, Sheffield, Windsor, Worthing, Salisbury, Oxford, Leatherhead, Stoke-on-Trent and Scarborough (both outstanding for production in-the-round), Coventry (1958; the first to be built out of public funds and the first new theatre built in Great Britain for 20 years), Colchester, Richmond, and Guildford.

*The National Theatre.*—In 1949 Parliament passed the National

Theatre Act, empowering the Treasury to make a grant of £1,000,000 to build a National Theatre. In 1951 the queen mother laid the foundation stone on a site on the south bank of the Thames overlooking the river, given by the London County Council. Successive governments put off building the theatre until, in 1963, the government decided to finance a National Theatre Company, which opened under the directorship of Sir Laurence Olivier (1907- ), with the Old Vic as its temporary home. In 1966 the government agreed to contribute half the cost of a building containing two auditoriums, the Greater London Council (as the London County Council had become) contributing the rest.

For amateur theatre, other than that represented by the "club theatres" and the provincial "little theatres," see BRITISH DRAMA LEAGUE.

**3. Ireland.**—Apart from the Abbey Theatre (q.v.; which reopened in a new, larger, building in 1966, after destruction by fire in 1951), nearly all that is best in Anglo-Irish theatre has been created by the Dublin Gate Theatre, founded in 1928 by the Irish actor and dramatist Micheál MacLiammóir (1899- ) and the English producer Hilton Edwards. Their policy of presenting a mainly international repertoire, but providing a theatre for Irish playwrights to write plays less local in character than those produced at the Abbey, resulted in new styles and techniques, and in familiarizing Irish audiences with plays by Ibsen, Strindberg, Chekhov, O'Neill, Elmer Rice, and Arthur Miller, as well as works by new Irish dramatists, notably Denis Johnston (1901- ).

Gaelic theatre arose from the work of Douglas Hyde (q.v.), author of the first play in Gaelic to appear on any stage (Abbey Theatre, 1901). Gaelic drama was encouraged by the Gaelic Drama League, working in Dublin, Galway, and provincial towns and villages. From 1928 to 1931 the Galway Gaelic Theatre, founded by MacLiammóir, produced plays in Gaelic, and translations of English and other foreign plays; and in 1931 the government-subsidized Dublin Gaelic Theatre was opened, with MacLiammóir as director.

The Irish national revival, centred in Dublin and led by Yeats and Lady Gregory (see IRISH LITERATURE: *Anglo-Irish Literature*), had its counterpart in Belfast, where the Ulster branch of the Irish Literary Theatre founded the Ulster Theatre (1902), which in 1939 was reconstituted as the Ulster Group Theatre, incorporating smaller semiprofessional organizations. With the Belfast Repertory Theatre, it aimed to portray Northern Irish life.

**4. U.S.S.R.**—The history of modern theatre in Russia began with the founding of the Moscow Art Theatre (q.v.) in 1897 by Konstantin Stanislavski and Vladimir Nemirovich-Danchenko (q.v.). For 12 years Stanislavski had worked with a company of amateurs, and the best of these, turned professional, formed the nucleus of the Moscow Art Theatre Company. When Stanislavski began, the Russian theatre was one of the most backward in Europe: acting consisted mainly in selecting from a stock of theatrical clichés whatever seemed most appropriate, and little time was spent in rehearsal. The plays, mainly French comedies and farces or Russian imitations of them, were so stereotyped that the same performances and sets could, with a slight variation, be used time after time. The first three productions at the Moscow Art Theatre caused no particular stir. It was Chekhov's *The Seagull* (1898) that established the theatre and Stanislavski's reputation. The quietness, intimacy, and naturalness of the acting were entirely new. (See also ACTING, DIRECTION AND PRODUCTION: *Acting: Stanislavski*.)

While Stanislavski continued to develop his infinitely detailed method of direction, the antirealist movement initiated by the Symbolists and Surrealists spread to Russia. Its criticisms came when Stanislavski was beginning to feel that he must seek new paths. In 1905 he founded a small studio theatre for experiment and research, appointing Vsevolod Meyerhold (q.v.) director. A member of the Moscow Art Theatre Company, Meyerhold had left it in 1902 when he became a convert to the Symbolist movement. When, after months of preparation, Meyerhold staged two productions, Stanislavski disliked them so intensely that he closed the studio. He thought the actors had been used as puppets to illustrate Meyerhold's theories. Yet these productions had an

important effect on him as a demonstration of the slavish obedience to which the dictatorial producer could reduce his actors. He determined that henceforth the actor should be his collaborator, not his subordinate, and began to develop the method of "inner realism" that became known as the Stanislavski method and remains the basis of the training of Russian actors.

After the 1917 Revolution Stanislavski refused to allow his theatre to become a platform for spreading propaganda. He believed that its mission was to maintain a standard of acting that other theatres might emulate when the first excesses of the Revolution had abated. The official edict decreed that characterization, ideas, and emotions should be reduced to the simplest possible terms for the new audiences, many of them illiterate. This amounted to a command to actors to overact, abandoning all subtleties and returning to the crude, melodramatic style. As some of Stanislavski's company were influenced by the enthusiasm with which the new audiences acclaimed overacting, he decided to take his company abroad and in 1922 left on a tour of Europe and the U.S. On return (1924), deciding that the Moscow Art Theatre must to some extent adapt itself to the mentality of the new audiences, he began to produce in bold, sweeping strokes, stressing the dramatic elements and enlivening comic scenes with tricks borrowed from vaudeville. There were no half tones, no subtleties, but none of the crude exaggerations of the contemporary Soviet theatre.

Meanwhile, Meyerhold had become one of the most powerful influences in the Russian theatre. He declared that the principles of the propagandist theatre conformed with those of Marxism because they attempted to underline "the elements which make prominent what is common to all men, the unindividual." Detailed portrayal of emotion was described as "worthless soul junk," and the actor ordered to "forget his little rickety ego" and become "an instrument for social manifestos." Many other producers, educated to despise an individualistic society, exercised ingenuity to deprive actors of individuality. Aleksandr Tairov (1885-1950), founder of the Kamerny Theatre (1914), made his actors wear fantastically exaggerated makeup so that they would not resemble anyone in real life and thus become individuals to the audience. Tairov invented the "constructivist" setting, a gaunt scaffolding supporting bare platforms on different levels, with every strut and bolt exposed to view. The aggressive functionalism of this kind of setting was regarded as having considerable propaganda value when the Russians were being taught to revere the machine as part of their training to become a great industrial nation.

A more moderate director was Evgeni Vakhtangov (1883-1922), a pupil of Stanislavski. In 1914 he was in charge of one of the studios attached to the Art Theatre, and in 1920 was appointed director of this subsidiary, renamed the Third Studio (or Workshop). But Vakhtangov was not altogether in accord with the quiet naturalness of the Art Theatre. His natural exuberance impelled him toward a style of production that, while avoiding the extreme stylization and unrealism of Meyerhold and Tairov, nevertheless enlarged, heightened, and sharpened character, emotion, and gesture. He wanted to work in vivid colours instead of half tones. In place of Stanislavski's inner realism he wanted what he called "outer-technique." He found the ideal actors for his purpose when Stanislavski put him in charge of a group of Jewish players who in 1916 had formed a company for production of plays in Hebrew, calling themselves the Habima Players. In 1918 they became affiliated with the Art Theatre. Vakhtangov's masterpiece was his production of Rappoport Ansky's *The Dybbuk* (1922). It was his last production; but for many years the Habima Players included his *Dybbuk* in their tours of Europe and the U.S., so that it became, outside the U.S.S.R., the best-known Soviet production. (See also HABIMA THEATRE.)

The youngest postrevolutionary director was Nikolai Okhlopkov (1900-66). His earliest productions were entertainments given during World War I on an improvised platform in the square of his home town to entertain the troops, who encircled the stage. As a result of this experience of the open stage he found the proscenium theatre cramping, and in Moscow experimented with ways of breaking down the barrier between actor and audience.

In 1932 he became director of the Realistic Theatre, where for his production of Aleksandr Seralimovich's *The Iron Flood* he converted the auditorium into a mountainous terrain, seating the audience among the rocks so that actors, playing in every part of the auditorium, mingled with audience. He made other experiments in staging, but in 1938 the Realistic Theatre was closed on the grounds that his work appealed too exclusively to intellectuals. By this time the experimentalism that had made the Russian theatre the most exciting in the world had ended. In 1934 Meyerhold, censured for his "obsession with the vague abstractions of decadent art," and for being "the father of formalism," was deprived of his position. Tairov, rebuked for being out of touch with his audiences, had been relieved of the direction of the Kamerny Theatre and forced to work under a committee. It is true that their work was too cold and abstract to please audiences who wanted warmth, humanity, and reality. But under Stalinism the theatre virtually ceased to progress, since any originality was condemned as decadent. Scenery became more and more laboriously realistic, as a setting in any way impressionistic was condemned as belonging to "abstract art." Only the magnificent standard of acting remained unchanged.

After Stalin's death (1953) the theatre was relieved of many shackles and there was a cautious return to experiment, particularly at the Satire Theatre. Okhlopkov, only survivor of the experimentalist producers of the 1920s, remained the most original and stimulating director, though at times under Stalinism his originality had displeased the authorities and he had been criticized for too unruly an imagination.

In the 1960s the Soviet theatre was perhaps at its best in productions of the classic Russian authors, directed with meticulous care, and reproducing the manners and customs of the Tsarist days. Its unique feature was its gigantic scale—the vast number of theatres, the fact that there were companies playing in more than 50 languages, the size of the companies (100 actors was not unusual), the size of the repertoire of each theatre, the huge and superbly equipped stages showing a succession of elaborate scenes, the size of the theatregoing audience, and the vast state subsidies to theatres, so that they need not attempt to pay their way and thereby could keep their prices low. The professional theatre could not satisfy the demand for dramatic entertainment and every encouragement was given to the amateur. Most theatres accepted responsibility for at least one amateur group, the members or the company giving much time to training and advising it. Amateur companies of outstanding merit were given the title "people's theatre." Most of these companies were based at Palaces of Culture, and toured neighbouring towns, as well as playing in factories and collective farms. The close relations between professional and amateur were mutually beneficial, for professionals found that contact with the personnel of the amateur groups infused freshness and reality into their own performances. By the late 1960s there was an even greater loosening up: satire, even political, became increasingly dominant, and methods and techniques increasingly experimental and symbolic.

**5. Germany.**—The character of the German theatre was changed during the early 20th century by the work of the Austrian Max Reinhardt (q.v.). When in 1903 he gave up acting for direction, the theatre was an educational institution rather than a place of entertainment; producers of the classics had to be scrupulously faithful to cherished traditions and conventions. Reinhardt loved colour and gaiety, richness and display, and these were the qualities he brought to his productions. He was attacked by the traditionalists and by the new school of German realists. What they disliked about his work was its theatricality, a quality scrupulously avoided in their own low-toned productions. One of his great services to the German theatre was that he restored its theatricality—but purged of staginess. In so doing he revolutionized German acting. In productions of modern plays he taught his actors a style realistic in feeling but avoiding the drab, painstaking exactness of the realists; it was warm, vivid, and colourful, always a little larger than life. In productions of the classics he demanded lively, supple speaking in place of the slow, ponderous delivery of the traditionalists. He made his actors think afresh about the

characters instead of assuming ready-made characterizations. When in 1906 he opened his Kleines Theater in Berlin, he initiated a movement that grew steadily. It aimed to break down the separation of stage and auditorium and to restore intimacy between actor and audience. In his endeavours to rescue the players from their isolation behind the proscenium arch, he often took them out of the theatre to play in places that seemed eccentric settings for a theatrical entertainment—a square in Venice, a palace ballroom in Vienna, the Boboli Gardens in Florence, and the Domplatz (cathedral square), where every year he directed Hofmannsthal's *Jedermann* (*Everyman*) at the Salzburg Festival, and inside the cathedral itself. He produced *Oedipus Rex* (Vienna, 1910) in a circus arena, using one end for gigantic architectural settings unframed by any proscenium. For his production of the mimed religious play, *The Miracle* (London, 1911), he transformed the huge Olympia exhibition building into a cathedral so that the audience became part of the congregation. But although he was a master of spectacle, his versatility was such that he directed subtle and intimate plays in small theatres with equal skill. Until World War I his personality dominated the German stage; nearly all the young directors and actors had either worked in one of his companies or been trained in one of his schools.

Immediately after World War I two of his disciples, Leopold Jessner (1878– ) and Erwin Piscator (1893–1966), became the dominant figures. Their Expressionist style of direction was evolved partly because of the shortage of materials for building scenery. In their antirealistic productions, actors on a bare, darkened stage were picked out by shafts of light against a black background; scenery was limited to one or two small pieces, symbolic rather than realistic. Stylized staging inevitably led to stylized acting, which in turn demanded stylized writing, and it was thus that the German school of Expressionist drama was created (see GERMAN LITERATURE; DRAMA: *Modern Drama*). Characters became symbols instead of people, their lines stripped of all but key words and phrases. Later in the 1920s, when steel, timber, and other materials became more plentiful, Piscator directed a series of Expressionist productions in which he used elaborate and expensive machinery. The front of his stage was constructed on the conveyor-belt principle; in the centre a cantilever bridge moved up and down; lantern slides and motion-picture films were projected onto the back wall; above the proscenium slogans blazed in lights; the gigantic shadows of pulsating machines were thrown onto gauzes. Jessner, too, made exuberant use of the lifting of restrictions on use of building materials. His favourite setting was a vast flight of steps extending the entire width of the stage, rising steeply to a high platform at its back. He was greatly influenced by the work of the Soviet directors of the immediate post-revolutionary period, and copied them in oversimplifying characters and their motives, abandoning subtlety for elementary Symbolism. The Expressionist movement ended because when an actor is reduced to a puppet he can only express a few emo-

tions, and those only in simple forms.

This phase was followed by a period in which the theatre reverted to realism. When the Nazis assumed power (1933), their passion for vast meetings and processions was reflected in vast propaganda dramas presented in the open air in sports stadiums, parade grounds, and on huge natural sites. World War II destroyed many theatres but popular desire for theatre and opera was so intense that rebuilding started immediately. A great opportunity presented itself for building theatres of new design, but many were still based on the picture-frame stage, often elaborately mechanized for the handling of huge, realistic settings. By the 1960s, however, experimental theatres were being built, at Dortmund, Trier, and Wuppertal (1966), for example.

The most important influence in the post-World War II theatre was the East German dramatist, poet, and producer, Bertolt Brecht (*q.v.*). After the early 1930s, when Reinhardt and other leading players and directors went into exile, acting lapsed into exhibitionism and splurgy emotionalism. Brecht, a disciple of Meyerhold, made constant use of his anti-illusionist devices to emphasize his dictum that "the actual world exists and is our subject; but this play and this stage are not it." For instance, to destroy the illusion of actuality he flooded his stage with white light throughout the performance, irrespective of when the action took place. Between scenes, captions, slogans, and comments were projected onto a gauze curtain. Points were emphasized by songs unrelated to the action: what Brecht called "musical addresses to the audience," in which the actor stepped out of and commented on the play. Brecht's theory of acting was a reversal of Stanislavski's doctrine that the actor must identify himself with the part he is playing. He demanded an objective style of acting. It was to

free the audience "from the spell cast upon them by the witchcraft of realistic producers who make a dream world of reality" that he evolved what he called "the alienation effect." After his death in 1956, his company, the Berliner Ensemble, under his widow, the actress Helene Weigel, continued to train actors and toured widely with a repertoire of his plays.

In spite of the number of theatres and the money lavished upon them in government and municipal grants, there were few signs in the 1950s of any strongly progressive movement, and few directors sufficiently dominant to impose a distinctive style. Much of the best creative work was done in the opera houses. But, after a revival of German drama, mainly by Swiss-German playwrights (e.g., Max Frisch, Friedrich Dürrenmatt, and Peter Weiss), the theatre throughout Germany began to revive, and the work of such dramatists as Günter Grass, Siegfried Lenz, Reinard Kipphardt, and Rolf Hochhuth provided opportunities for original direction and staging.

**6. France.**—The reaction against realism, in the early 20th century a powerful influence in the German and Russian theatres, was slower to reach France. The founding of the Théâtre du Vieux Colombier by Jacques Copeau (q.v.) in 1913 initiated the reaction. Copeau was a literary critic who set up his own company. Like Reinhardt, he sought to break down the barrier between actor and audience. His stage was unframed; there were no wings and no line of demarcation between stage and auditorium. Decor, used sparingly, seldom consisted of more than one or two painted screens, a balustrade, or a draped curtain. Only the minimum of furniture and properties was used. The atmosphere for each play was created almost entirely by lighting.

Before opening the Vieux Colombier, Copeau took his company to Le Limon, where they improvised scenes and practised exercises. They learned much from Charles Dullin (1885–1949), a *disneur* in the Montmartre cafés and an exponent of traditional *comédie improvisée*, still popular in Parisian cabarets and provincial fairs. The acting at the Vieux Colombier in a modern play was at first sight realistic, although the detailed business was minimized; but closer watching showed that gesture was being used selectively to give each gesture unusual significance. Copeau's productions of Molière and Shakespeare were notable for lightness, grace, and gaiety. In 1923 he took a group of young actors to Burgundy, where, besides studying acting, they worked in the fields and in a carpenter's shop and took part in the local wine festival. The peasants called them "Les Copiaux," under which name they first appeared at Basel, Switz., in 1926. Their characteristic production was *La Danse de la ville et des champs*, written and produced by Michel Saint-Denis (1897– ), who in 1930 took over the company, renamed the Compagnie des Quinze. It was disbanded in 1936 but had become internationally famous. The company had its own playwright, André Obey (1892– ), who wrote to suit its methods and talents.

Copeau's influence was strengthened and extended through the productions of Louis Jouvet (q.v.) and Dullin, who left his company in 1922 to start their own theatres. Jouvet's productions of Molière were his most important contribution. He freed the plays from the weight of tradition that was stifling them. His *L'École des femmes* (1936) was hailed as a return to the spirit of Molière. While Jouvet was careful to subjugate himself to his author, Dullin's productions were strongly coloured by his own personality and tastes. He loved bright colours, music, movement. Copeau's influence was apparent in his use of expressive gesture and mime. His production of Aristophanes' *The Birds* (1928) mingled the carnival and social satire that he sought in nearly every play he produced. In contrast to Dullin was the criticism of Georges Pitoëff (1887–1939), who believed that the director's primary aim should be to focus attention on a play's central idea, and eliminate all details of decor and acting that might obscure it. His great contribution to the French theatre was the number of foreign dramatists whom he introduced to the Parisian public.

Jouvet, Dullin, and Pitoëff, with Gaston Baty (1885–1952), were known as *Les Quatre* ("The Four"). Baty had served his apprenticeship under Reinhardt. His pictorial sense was superb,

and his groupings and movement were beautifully composed, but they existed for themselves rather than for the play. He was often accused of overelaborating the classics to display his inventiveness, but he directed the delicate plays of Jean Jacques Bernard (q.v.) with infinite subtlety.

Dullin's use of mime was elaborated in the productions of his pupil, Jean Louis Barrault (1910– ), who left the Comédie Française in 1946 to form, with his wife, the actress Madeleine Renaud, the Compagnie Renaud-Barrault, which played in the provinces and abroad and, in Paris, at the Théâtre Marigny. In 1959 he became director of the Théâtre de France, to which in 1966 the annual "Théâtre des Nations" was transferred. Much of his work is symbolic—a combination of pantomime, rhythmic movement, and shadowgraph. He has been accused, rather unfairly, of being "an enemy of speech." He became the chief exponent of "total theatre," a theory evolved by Gordon Craig (q.v.). Another pupil of Dullin, Jean Vilar (1912– ), in 1951 founded the Théâtre Nationale Populaire (T.N.P.). His style was governed by the size of the Palais de Chaillot, a theatre seating nearly 3,000 with a stage 70 ft. (more than 21 m.) deep and a proscenium opening 80 ft. (more than 24 m.) wide. Vilar made no attempt to fill the stage with scenery. He did no more than suggest the background of the play, and filled his stage with big, swirling movement. He trained his actors to use bold, simplified gestures and delineate character in powerful outline.

Until the 1950s theatrical activity was almost entirely concentrated in Paris, but with government help theatrical centres were established at Strasbourg, Aix-en-Provence, Saint-Étienne, Toulouse, and Reims.

**7. Other European Countries.**—In northern Europe in the 1960s the largest audience was in Finland, where more than a quarter of the population were regular theatregoers. The number of plays by native authors was unusually high. Few have been performed abroad because of lack of good translations. In Denmark, production of a Danish play was comparatively rare, but a variety of foreign plays was produced. In Sweden, where the number of native playwrights was increasing, good theatre was spread over the country. Göteborg rivaled Stockholm, and both were challenged by Malmö, Uppsala, Norrköping, and Hälsingborg. The Norwegian theatre has spent most of its life in financial crisis, partly because audiences have been scanty. It had to rely on private enterprise—even the National Theatre was founded in 1899 without state or municipal aid—until in 1961 the government took over financial responsibility for the whole theatre. To take the theatre to the people it founded the State Traveling Theatre, which played even in small villages beyond the Arctic Circle.

In eastern Europe the most advanced theatres were in Poland and Yugoslavia. Both were molded by great producers whose work has been continued by their pupils. In Yugoslavia, Branko Gavella (d. 1962) was for nearly 50 years a free-lance producer, striving to improve standards and encourage originality. In Poland the work of Leon Schiller, a disciple of Gordon Craig, was continued by his most brilliant pupil, Erwin Axer. In Bulgaria, Rumania, and Czechoslovakia development was hampered by subservience to socialist realism, but by the 1960s playwrights were beginning to write with more freedom and sophistication, and Josef Svoboda (1920– ), chief designer at the National Theatre, Prague, after 1950, was the world's leading scenic designer. After World War II the number of Rumanian theatre companies increased from 18 to 32, and Czechoslovakian theatres more than trebled. The Hungarian theatre, perhaps because of its situation, was the most cosmopolitan in its choice of plays. Never respectful of the dictates of socialist realism, it was a gay and sardonic theatre, excelling in satirical topical revues.

**8. British Commonwealth.**—The birth of motion pictures was practically the death of the theatre in Commonwealth countries. After World War II, visits of English companies to Canada and Australia stimulated a rebirth. In Australia, in 1954, the Queen's first visit was commemorated by the formation of an Elizabethan Theatre Trust to encourage drama, opera, and ballet. Two-thirds of the sum was contributed by the public, the remaining third by the government. The Majestic Theatre, Sydney,

renamed the Elizabethan Theatre, became the trust's headquarters, and Hugh Hunt, director of the Old Vic, its first director.

In Canada the Festival Theatre at Stratford, Ont., was opened in 1953 to give summer seasons of Shakespeare. At first it was housed in a huge tent, but in 1957 a permanent theatre was built to Sir Tyrone Guthrie's design. Guthrie, founder of the festival, became resident director, and a number of British stage stars appeared with the company but the theatre has become increasingly able to rely on Canadian actors. A National Theatre School was founded in Montreal, Que., teaching in French as well as English. In Toronto, Ont., the Crest Theatre, directed by the Davies brothers, gave a wide variety of plays; but it was symptomatic of the shortage of good Canadian playwrights that the company appeared in London in a play by an English author. In 1960 the O'Keefe Center, a large, well-equipped modern theatre, was opened in Toronto.

New Zealand is a difficult country for professional theatre because even in the large cities the population is too small to support a permanent company and distances between towns make touring expensive. In 1960 the only professional company, the New Zealand Players, was forced to abandon touring for lack of financial support. However, in 1961 Richard Campion, who had formed the Players, helped to organize the New Zealand Theatre Company; this toured one production a year and had a grant from the government arts council.

Kenya had a National Theatre in Nairobi, opened in 1956. It is largely devoted to amateur companies, European, African, and Asian, including some that drew their members from all three. Nairobi also had for many years the only professional company in east Africa, the Donovan Maule Players, recruited mainly from England. In 1959 they moved into a finely designed new theatre. In Kampala, the capital of Uganda, a National Theatre was opened in 1959 and was run in much the same way as the Kenya National Theatre. In both Uganda and Nairobi annual drama festivals showed a continual rise in the quality and quantity of plays by African authors dealing with African life.

**9. South Africa.**—The theatre in South Africa at first relied mainly upon foreign touring companies, but during the 1950s it became mainly self-supporting. The National Theatre Organization, founded in 1948 with a government subsidy to take drama, in English and Afrikaans, to all parts of the country, had its headquarters in Pretoria, and in the 1960s had several companies with portable stage sets touring the country districts. Johannesburg continued to be the main theatrical centre with such permanent companies as the Brian Brooke Company, started in the 1930s, and the Johannesburg Repertory Players founded in 1947. Cape Town had the Cockpit Players, run by Leonard Schachs, and the Hofmeyr Theatre with its own company.

Negro theatre in South Africa was unorganized, depending on the vitality of township jazz concerts. Late in the 1950s the African Drama Trust was founded to try to give it coherence, and in 1961 a section of the National Theatre Organization was set up for Bantu drama. In the same year a Bantu company scored a London success with *King Kong*. (N. M.)

**10. United States.**—In the first decade of the 20th century, realism dominated the American theatre: in the plays of Clyde Fitch, William Vaughn Moody, and Edward Sheldon; in the acting of Mrs. Fiske, Richard Mansfield, and Ethel Barrymore; and in the productions of David Belasco and Harrison Grey Fiske. At the same time, however, the pretty operettas of Victor Herbert and the brash musical comedies of George M. Cohan were popular. The first *Ziegfeld Follies* appeared in 1907. The New Theatre in New York City, with a resident company dedicated to art rather than business, was established in 1909 but collapsed after two seasons.

Visits of the Abbey Theatre in 1911, Reinhardt's *Sumurun* in 1912, Granville-Barker's Company in 1915, and Copeau's group from the Vieux Colombier in Paris in 1917 provided exciting glimpses of the work of Europe's art theatres and of the "new stagecraft," thus adding to the growing dissatisfaction with the U.S. theatre.

The modern period on Broadway may be said to have begun in

1918 with the establishment of the Theatre Guild (q.v.), the first commercially successful U.S. art theatre, for in the next decade occurred a flowering that placed U.S. theatre for the first time on a par with the best theatre of Europe. Eugene O'Neill emerged from the Provincetown Players (q.v.) in 1920 with *Beyond the Horizon* to win worldwide fame. He was quickly followed by Sidney Howard, Robert Sherwood, Maxwell Anderson, George Kelly, Elmer Rice, S. N. Behrman, Philip Barry, and others; their plays provided an expression of American life that was unprecedented in its richness and variety. Besides the Theatre Guild, such producers as Arthur Hopkins, Gilbert Miller, Winthrop Ames, George C. Tyler, and Kenneth Macgowan staged the new American drama, interesting new plays from abroad, and some classics in the new style. Designers Robert Edmond Jones, Joseph Urban, Lee Simonson, Cleon Throckmorton, Norman Bel Geddes, and Jo Mielziner provided distinguished settings that were realistic, symbolic, or expressionistic as required by the new drama. The Moscow Art Theatre company visited New York in 1923 and impressed with the quality of its ensemble acting, which only a permanent organization could achieve; some of its members remained in New York to teach the Stanislavski system. In 1926 Eva Le Gallienne established a permanent repertory company that presented classics old and new. *Show Boat* appeared in 1928 and became a classic of the musical stage. Outside New York City, competition from motion pictures reduced the number of theatres open to traveling companies from 1,500 in the early 1900s to 500, but on Broadway the number of productions grew from 150 in 1920–21 to 280 in 1927–28.

The stock market crash of 1929 heralded the end of unparalleled prosperity in the theatre and in the nation. The nation recovered from the ensuing economic depression, but the theatre, under increasing competition from motion pictures, radio, and television, did not. In the next 30 years traveling companies all but disappeared, and productions on Broadway shrank to 60 in 1949–50, and thereafter averaged between 60 and 70 a year. No new theatres were constructed. The Civic Repertory Theatre succumbed in 1933.

Nevertheless, live theatre continued to attract talented writers: Clifford Odets, Sidney Kingsley, Lillian Hellman, Thornton Wilder, and William Saroyan beginning in the 1930s; Tennessee Williams, Arthur Miller, and William Inge in the 1940s, and Edward Albee in the 1960s. Rising costs encouraged simplification of setting and by 1950 the box set was seldom seen. Rising costs and shrinking audiences necessitated longer runs. Enterprises outside the standard pattern, however, enjoyed some success. The Group Theatre (q.v.) for ten years maintained a permanent company, developed new playwrights, and evolved a new acting style based on the Stanislavski system. From 1935 to 1939 the Federal Theatre Project (q.v.) presented hundreds of productions of all sorts and showed that a large untapped audience existed for live theatre at low prices. From 1937 to 1939 Orson Welles and John Houseman maintained a permanent company and limited runs in the Mercury Theatre. From 1947 the Actors Studio cultivated the "method," derived from Stanislavski's system and practised by such actors as Marlon Brando, Geraldine Page, and Julie Harris. In 1955 the first U.S. Shakespeare festival was held at Stratford, Conn., and it became more popular each summer. The American National Theatre and Academy (ANTA), chartered by Congress in 1935 and activated in 1946, encouraged theatre, professional and nonprofessional, throughout the country. As theatre activity decreased, the producer declined in importance and the stage director rose. Among the important directors in the 1940–60 period were Elia Kazan, Robert Lewis, Harold Clurman, Joshua Logan, and José Quintero.

The musical show after 1930 gained in polish and sophistication. In 1935 George and Ira Gershwin turned the play *Porgy* by DuBose and Dorothy Heyward into America's first successful folk opera, *Porgy and Bess*. Later examples were: *Pal Joey* (1940), *Lady in the Dark* (1941), *Oklahoma!* (1943), *South Pacific* (1949), *My Fair Lady* (1956), and the star-vehicle productions *Hello, Dolly!* (Carol Channing), *Funny Girl* (Barbra Streisand), and *Fiddler on the Roof* (Zero Mostel), all in 1964. (See Mus-

CAL COMEDY.)

**Off-Broadway Theatre.**—Plays have always been produced in small theatres outside as well as in the main theatrical district in New York. In 1915–18 the Washington Square Players, in the 1920s the Provincetown Players, and in the 1930s the New Playwrights drew audiences and critics off Broadway. A new era began in 1952 with the successful revival of Tennessee Williams' *Summer and Smoke* at the Circle in the Square and gained momentum with productions at the Phoenix, the Theatre de Lys, and the Fourth Street Theatre. In 1961–62, the *New York Times* counted 100 off-Broadway productions, 34 more than on Broadway. From 1962–63 the number of off-Broadway productions declined.

Revivals of classics and of recent plays that had failed on Broadway predominated at first, but the proportion of new plays increased. With a few exceptions, such as at the Phoenix, the single play and the long run predominated. Since production often took place in improvised quarters under makeshift conditions, it showed styles and forms seldom seen on Broadway. Many productions were staged without a proscenium arch and with the audience on two or three sides of the playing area. Actors, directors, designers, and producers who achieved success off Broadway were soon active on Broadway. And Broadway successes began to appear off-Broadway, attracted by the greater freedom.

**Summer Theatre.**—Declining production on Broadway was accompanied by a growth of theatre in resort areas during the vacation season. In 1940, 80 summer theatres were open for a ten-week season, performing a different play or musical each week in tents, barns, and sometimes in regular theatre buildings. By the 1960s more than 200 such "straw-hat" theatres were in operation. Resident companies, frequently augmented by visiting stars, usually performed recent Broadway successes. Occasionally these summer theatres were used to test new plays for possible Broadway production. (See also below, *Drama Festivals*.)

**The Negro in the U.S. Theatre.**—In native plays, the Negro appeared first as a plantation hand, a minor comic character. Later he was frequently seen as a comic domestic servant. In the 1830s Thomas Dartmouth Rice was extremely popular singing and dancing as the eccentric "Jim Crow" in an entertainment he called "Ethiopian Opera." Out of such white performances of Negro song and dance came blackface minstrelsy (see *MINSTREL SHOW*). Edward Harrigan introduced the city Negro in his comic Mulligan plays of the 1880s. The slavery plays like *Uncle Tom's Cabin* (1852) and the Civil War plays like *The Reverend Griffith Davenport* (1899) were the first to treat the Negro seriously. Edward Sheldon's *The Nigger* (1910) was the first play to deal with Negro problems in modern society. After the Civil War, Negroes became popular in minstrel shows and in all-Negro musicals.

From 1910 on, individuals like Bert Williams were featured in musicals like the *Ziegfeld Follies*; the integrated musical appeared in the 1940s. Negroes gained recognition in serious drama somewhat later: Charles Gilpin in *The Emperor Jones* (1920), Richard Harrison in *The Green Pastures* (1930), Canada Lee in *Native Son* (1941), and Paul Robeson in *Othello* (1943). Playwrights who contributed to the drama of Negro life include Ridgely Torrence, DuBose and Dorothy Heyward, and Paul Green. Negro playwrights had little success on Broadway until Lorraine Hansberry's *A Raisin in the Sun* became a hit in 1959. The racial ferment of the 1960s created an audience for accusatory melodramas

such as *Dutchman* (1964), by the poet LeRoi Jones, and *Blues for Mr. Charlie* (1964) and *The Amen Corner* (1965), by the novelist James Baldwin. In *White America* (1964), a documentary of 300 years of Negro grievances, by Martin Duberman, became a major propaganda piece of the civil rights movement.

**Community Theatre.**—Community theatre grew out of the little theatre movement and its art theatres that sprang up (c. 1900–25) in protest against the commercial theatre and under the inspiration of the free theatres of Europe. Among the leaders were Gilmor Brown in Pasadena, Calif., Frederic McConnell in Cleveland, O., Samuel J. Hume in Detroit, Mich., and Maurice Browne in Chicago. The little theatres presented noncommercial plays, European and American, with the "new stagecraft," in small theatres for small audiences.

As road companies disappeared, most of these organizations lost their "art" theatre aims and became substitutes for professional theatre, presenting popular plays in larger theatres to larger audiences with more paid personnel. By the late 1960s three types of community theatres existed: (1) a growing number with paid actors and staff, like the Arena Stage, Washington, D.C., and the Minnesota Theater Company in Minneapolis, of which Tyrone Guthrie was artistic director; (2) a few more with paid staff and a few paid actors, like the Cleveland Play House; and (3) the great majority with some paid staff only. A new form of subsidy in the 1960s was exemplified by Ford Foundation grants to the Alley Theatre in Houston and the Actor's Workshop in San Francisco.

**University Theatre.**—Dramatic performances by students go back to the colonial period, but instruction in theatre subjects did not enter the curriculum until about 1900, largely in colleges of liberal arts and as part of the reaction against commercial theatre. Early leaders in this movement included George Pierce Baker at Harvard, Thomas H. Dickinson and Gertrude Johnson at Wisconsin, and Frederick H. Koch first at North Dakota and later at North Carolina. In 1914 the first department offering training for the professional theatre was established, at Carnegie Institute of Technology under Thomas Wood Stevens. After World War I, under the leadership of such men as A. M. Drummond at Cornell, E. C. Mabie at Iowa, and Glenn Hughes at Washington, there was a tremendous expansion of courses, departments, and degrees. The National Theatre Conference of leading university and community theatres was organized in 1932. The American Educational Theatre Association was established in 1936 and after 1949 published the *Educational Theatre Journal*. By 1964–65 nearly 600 college theatres were producing annually about 3,000

plays for an audience of more than 7,000,000. Much of this growth was because of the disappearance of professional theatre outside New York City. Although the aims of university theatre have been primarily cultural, it has affected the professional theatre, especially off-Broadway. Its unique contributions have been the development of theatre for children and the popularization of arena and other forms of open staging. (B. Hr.)

**New Directions.**—The late 1960s were marked by a deepening commitment on the part of the universities to professional theatre and by novel developments in repertory. The University of California, Princeton University, and the University of Michigan directly encouraged professional theatre by hiring actors and playwrights or directors "in residence." On the Michigan campus, at Ann Arbor, the American Players Association, subsidized in part by the university, prepared productions for presentation off Broadway. The American Conservatory Theatre, directed by William Ball and sponsored originally by the Carnegie Institute of Technology, Pittsburgh, embarked on a similar campus-to-city venture, was notably successful in 1966 at the Ravinia summer festival near Chicago, and was considering the possibility of civic sponsorship jointly by Chicago and San Francisco for a split winter season. Meanwhile the tradition of professional road companies in repertory was upheld by the National Repertory Theatre, the Association of Producing Artists, and other touring groups; efforts continued to establish a resident repertory company in New York City at the Lincoln Center for the Performing Arts.

The Rockefeller Panel Report on the Performing Arts counted 56 permanent professional theatres operating in the U.S. in 1964-65; most of them had been recently established. (X.)

**11. Latin America.**—The theatre in Latin America varies greatly from country to country. Its development at mid-century was highest in Argentina, Mexico, Brazil, Uruguay, and Cuba in that order, with the other countries trailing considerably behind. The advent of motion pictures around 1900 brought about a decline in the theatre throughout Latin America but a theatrical revival became noticeable after the 1930s when playwrights abandoned the late 19th-century Spanish dramatists as models and introduced techniques and styles from the best European and New York theatres.

Early in the 20th century a nationalistic theatre arose in Argentina depicting the conflicts between the *criollo* population (descendants of settlers from the old world) and the immigrants. This movement produced a legion of playwrights, the best known of whom was an Uruguayan, Florencio Sánchez. His plays, written between 1903 and 1909, were mostly dramatic but others cultivated a more festive theatre, such as the Argentine *sainete* ("farce"). Modern Buenos Aires, Arg., had professional theatres, experimental and art theatres, and the Teatro Colón with its own opera company, symphony orchestra, and ballet. The Argentine motion-picture industry developed steadily until by

the 1930s it ranked second in America only to that of the U.S.

Although the Mexican theatre was not comparable to that of Argentina, it grew through the efforts of enthusiastic art groups and many exceptional dramatists, such as Rodolfo Usigli (*Corona de sombra*, 1947) and Xavier Villaurrutia (*Juego peligroso*, 1950). Beginning in the 1950s numerous theatres were built or halls adapted as *teatros de bolsillo* ("pocket theatres"). Mexico's motion-picture industry grew and by the middle of the century had surpassed Argentina's in volume. Mario Moreno (Cantinflas) became a world-famous motion-picture star.

In Brazil the theatre enjoyed generous official protection and a high level of theatrical culture resulted. The quality of Brazilian theatrical production was comparable to that of any country. Among the best-known modern Brazilian authors were Joracy Camargo (*Deus lhe pague*, 1932) and Guilherme Figueiredo (*A rapôsa e as uvas*, 1935). Procópio Ferreira came to be considered one of the world's greatest contemporary actors. The modern Brazilian motion-picture industry, commercially smaller than those of Argentina and Mexico, excelled technically and artistically.

Cuba, with a glorious theatrical past, witnessed a sharp decline at the beginning of the 20th century. The peculiar political satires known as *bufos cubanos* flourished for a while but dwindled away in the 1920s. In that decade and in the 1930s composers and playwrights developed the *zarzuela cubana*, a type of musical comedy that was successful at home, in Spain, and in Latin America. Among the composers of the *zarzuelas* were Ernesto Lecuona, Moisés Simons, and Gonzalo Roig. Cuba also made important

contributions to the theatre in the field of the ballet; the Cuban prima Alicia Alonso became internationally known. In the theatre was strongly encouraged through open-air performances and companies that traveled to the interior. From 1959 on, the Fidel Castro regime used the theatre as a propaganda vehicle. It came produced at least one outstanding playwright, Armando Maciá (*Rigoberto*, 1935).

The years following World War II were marked in Latin America by the appearance of many promising playwrights, among them Orlando Dragún of Argentina, Sergio Magaña of Mexico, Jorge de Andrade and Ariano Suassua of Brazil, Virgilio Piñera of Cuba, and Alejandro Sieveking of Chile. Occasional periods of censorship did not help to advance creative theatre. Prevailing outside influences were Ionesco, Brecht, and Tennessee Williams. There was a growing interest in social and political questions.

The motion-picture industry continued its upward trend both in volume and quality. At the region's first important motion-picture festival, held with considerable success in Rio de Janeiro in 1965, the Brazilian cineasts Glauber Rocha, Paolo Saraceni, Nelson Pereira Dos Santos, and others displayed much skill in offerings that exemplified their conception of *cinema novo*, reminiscent of Italian neorealism; this movement spread throughout Latin America. Prior to the festival one Brazilian picture, *Black Orpheus* (1959), had received universal acclaim. (L. A. B.)

**12. Drama Festivals.**—There were so many drama festivals in Europe in the 1960s that it was difficult to keep count of them. The most comprehensive was the annual "Theatre of the Nations" festival in Paris. The festivals in the Netherlands, Stockholm, Berlin, Zürich, Munich, and Vienna were, like the Paris festival, international. The Dublin Festival was essentially Irish, although some foreign companies were invited and performances of foreign plays given. The summer Pitlochry Festival in Scotland included a proportion of Scottish plays but was not exclusively national; nor was the Chichester (Sussex) Festival. At first the summer home of the National Theatre, the Chichester Festival Theatre was taken over in 1965 by a new company under the actor and producer John Clements. At Epidaurus, Greece, the festival was devoted to Greek classics. This was one of many open-air festivals, among which the most important were at Baalbek, Lebanon; Arles, France; and Dubrovnik, Yugoslavia. There were many smaller open-air festivals in France and Italy, most of which used surviving Roman theatres. The festivals at Salzburg and Edinburgh combined music and drama. The Edinburgh International Festival has given first performances of a number of distinguished plays, including two by T. S. Eliot, but much of the interesting drama was among the "fringe," the small pioneering companies, mostly youthful, that were not officially part of the festival.

Among festivals in the British Commonwealth were that at Adelaide, Austr. (1961–), modeled on the Edinburgh Festival; the Canadian Dominion Drama Festival, founded in 1932, with plays in English and French; and the Vancouver International Festival. In 1965 a Commonwealth Arts Festival was inaugurated in London, at which plays by African dramatists have been notably successful. (N. M.)

Some of the best-known summer drama festivals in the United States were devoted to Shakespeare. At Ashland, Ore., plays were presented outdoors in what resembled an Elizabethan public theatre. A similar repertory was presented in a reconstruction of the theatre at San Diego, Calif. At Stratford, Conn., plays were produced in a modern theatre. The New York Shakespeare Festival was staged in Central Park. Opera replaced spoken drama in the opera house at Central City, Colo. The Arts Festival at the Public Garden, Boston, Mass., included opera and ballet, as did the Richmond, Va., Festival of Arts.

Although Stratford, Ont., was best known for its productions of Shakespeare, its program included new plays, operetta, films, and music. Vancouver, B.C., presented an international festival of drama, opera, and ballet.

**THEATRE GUILD (NEW YORK)** was founded in 1918 for the purpose of offering consistently high-quality European and native drama to U.S. theatregoers. Recognizing the need for a professional organization that would produce with regularity, the first board assembled by the Guild's founder, Lawrence Langner (1890-1962), established the Guild as a permanent program theatre; the board departed from usual theatre practices, sharing responsibility for play choice, management, and production. The first two seasons, with plays by Jacinto Benavente, St. John Ervine, Tolstoi, John Masefield, and Strindberg, demonstrated the artistic soundness of the plan.

Following the world premiere of *Heartbreak House* in 1920, the Guild became the American agent of George Bernard Shaw, producing 15 of his plays, including world premieres of *Back to Methuselah*, *Saint Joan*, *Too True To Be Good*, and *The Apple Cart*. After its success with European authors, the Guild produced *Marco Millions* in 1928, which began Eugene O'Neill's long association with the Guild. Other American authors included Sidney Howard, William Saroyan, Maxwell Anderson, and Robert Sherwood; all Pulitzer Prize winners. Numerous other playwrights received the Critics Award for Guild productions of their plays.

Under its aegis, Lynn Fontanne and Alfred Lunt first made their appearance as an acting team in Ferenc Molnár's *The Guardsman*, continuing to act together for the Guild throughout most of their distinguished career.

Prominent among scenic artists, Robert Edmond Jones, Jo Mielziner, Stewart Chaney, Donald Oenslager, and Lee Simonson did major work under Guild sponsorship. Directors Philip Moeller and Rouben Mamoulian achieved their greatest successes in association with the Guild. A younger group of Guild staff, partly financed by the Guild, formed the Group Theatre in 1931. The

Theatre Guild contributed significantly to American musical theatre by producing George Gershwin and DuBose Heyward's *Porgy and Bess* and by bringing together Richard Rodgers and Oscar Hammerstein to adapt Lynn Riggs's *Green Grow the Lilacs* as a musical comedy. The resultant *Oklahoma!* established a new genre in musical theatre, its success being followed by other Rodgers and Hammerstein collaborations, including *Carousel*.

The "Theatre Guild on the Air," sponsored by the United States Steel Corporation, had a distinguished record of radio and television play productions (1945-63). The Guild's subscription series enabled audiences in 23 cities from coast to coast to enjoy its major attractions and those of other managers. (E. B. P.)

**THEATRES (STRUCTURES).** A theatre is a place or building so equipped that actors may perform, with or without scenery, before an audience.

**Greek Theatres.**—Although the temples of the ancient Egyptians may have provided the setting for their dramas, and the theatral area adjoining the palaces at Knossos and Phaistos, Crete (2000-1600 B.C.), may well have served as a place for ritual dances and ceremonies of a dramatic nature, it was in ancient Greece that the Western type of theatre began.

Greek drama developed from religious dances performed by a chorus on a flat area leveled off on the slope of a hillside, the audience standing on the slope above; often the most suitable ready-made site was the circular threshing floor. As drama developed, rudimentary theatres, like that at Ikaria, were provided for the performances; in the very early form of theatre (fig. 1), dating from the 6th or 5th century B.C., the audience sat, possibly on timber benches, on a simple earth slope facing a flat rectangular dancing floor (orchestra) where the chorus and actor(s) performed. Directly adjoining this was a small temple with an altar before it, a reminder of the religious nature of the dramatic functions. At Thorikos (fig. 2) three periods of development are observable: in the first (6th or 5th century B.C.), a rectangular section of stone steps faced a rectangular orchestra with a retaining wall at the rear; in the second, two slightly curved wings were added; finally in the third (3rd century B.C.), additional seating was provided above ground level.

Similar remains may exist beneath the later developments that cover most theatre sites continuing in active use. The most famous of these was the theatre of Dionysus in Athens. Here the extant 6th-century remains are generally accepted as part of the retaining wall of the earliest orchestra, and this wall is presumed to have followed a free form. No evidence seems to exist as to the shape of the orchestra itself, and, although this has been assumed to have been circular, the records regarding the use of timber benches seem to suggest the possibility of a straight-sided figure similar to that at Thorikos. The shape of the Periclean orchestra (c. 443 B.C.) is also in doubt, but it is known to have been backed by a long straight retaining wall. Although early orchestras may at first have been rectangular, then trapezoid or many sided, the need to provide accommodation with good acoustic and visual conditions for an ever increasing audience—everyone in the district attended the yearly religious festivals—probably accounted for the final adoption of the circular form. Little is known of this early period, however, and while the orchestra may have evolved as indicated above, the final form may have been strongly influenced by the early use of the threshing floors.

FIG. 1.—EARLY THEATRE FORM, WITH AUDIENCE SEATED ON HILLSIDE

FROM H. AND R. LEACROFT, "THE THEATRE"

FIG. 2.—THE GREEK THEATRE AT THORIKOS. A, B, AND C INDICATE THE THREE PERIODS OF DEVELOPMENT (SEE TEXT)

At first the only building connected with the theatres was a temple, but when plays developed from the early songs and dances and actors joined the chorus and played more than one part, they needed a changing room, so a booth or hut (*skene*) was built on the far side of the orchestra. At first the *skene* had one central door; later the door was flanked by two more doors and later still by two wings (*paraskenia*), each with a further door. Although it is contended that the actors were not separated from the chorus during the "high" period of Greek drama and that the need for a raised stage was only felt when the New Comedy of the 4th century B.C. required a clearer portrayal of individual characters, no one really knows when a raised stage was added. When it was adopted, however, it filled the space enclosed by the *skene* and *paraskenia* and consisted of a wooden platform or speaking place (*logeion*) supported at the front on a row of columns or piers, which, in later examples, were about 10–12 ft. high. These colonnades were known as the *proskenion*, although this term is usually applied to the whole stage structure in front of the *skene*, a view shared by the designers of the Renaissance.

Although no two Greek theatres are exactly alike and it is difficult to trace any simple line of development, most fully developed Greek theatres incorporated the following elements (fig. 3). A *cavea*, or *theatron*, of stepped stone seats for the audience was divided by gangways as shown. Seats of honour (*prohedria*) occupied the front row; when raised stages were added to existing theatres, these seats were often moved to a higher level or additional seats were installed. The seating surrounded, to slightly more than a semicircle, a circular orchestra that had two entryways (*parodoi*) beside the retaining walls at either end of the *cavea*. Beyond the *parodoi* and tangential to the orchestral circle was the *proskenion*, with its *logeion* often approached from either end

by a sloping ramp and backed by the *skene*. Entry to the stage from the *skene* was still through the three doors, which were now raised to the upper level; but by the 3rd and 2nd centuries B.C. the front wall of the *skene* was pierced by as many as seven wide openings (*thyromata*).

The earlier Greek plays were set in an open place before the homes of the various characters that were represented by the different doors, the central door representing the palace of the protagonist. Entry to the theatre from the sides represented variously an approach from the sea or from the country. Although interior scenes were not used in the early dramas except in the form of tableaux wheeled out on a low platform (*eccyclema*), the later *thyromata* may have made provision for them. Some authorities think these openings were curtained and contained scenery, but the actors could hardly have performed within the *skene* because many of the audience would have been unable to see them. It is sometimes thought that a convention allowed the action supposedly taking place within the opening to be performed on the open stage in front. Besides making these conventional uses of the architectural setting, the Greeks added realism in the form of various mechanical devices, such as the crane that enabled gods to ascend to or descend from a higher stage (*theologeion*). They also introduced painted scenery: the *pinakes* were decorative panels generally thought to have been placed between the columns of the *proskenion*; the *periaktos* was a three-sided machine that was revolved to suggest a change of scene by the display of a new device. Remains in some theatres suggest the *periaktos* were placed behind openings in the *skene*.

Although most stage buildings have largely disappeared, many *cavea* remain sufficiently intact so that their original appearance can be appreciated. One of the finest is at Epidaurus; it was designed by Polyclitus, c. 340 B.C. Many theatres, including that of Dionysus at Athens, underwent extensive alterations at the hands of the Romans, who usually paved the orchestra and enclosed it within a low wall to protect the audience during gladiatorial fights or to permit flooding for some nautical spectacles. Although it is unlikely that the Romans realized the Greek theatre had developed its form at a time when attention was focused on a chorus performing in the orchestra, they obviously felt that placing of the actors' stage on the far side of the orchestra was not desirable, and they rebuilt many stage buildings nearer the audience.

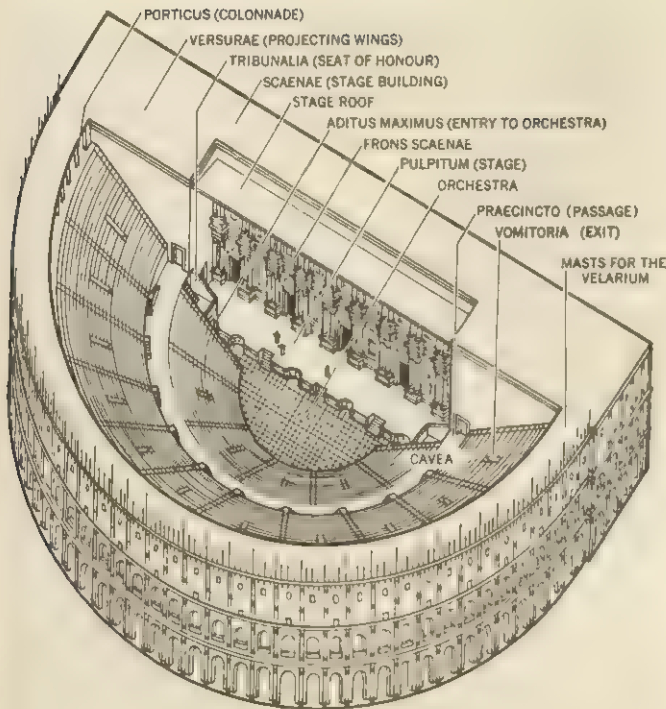

Temporary wooden stages were erected for the performance of Greek popular comedies (*phlyakes*) by strolling players. Vase paintings show timber platforms raised a few feet on posts, with

FIG. 4.—TYPICAL ROMAN THEATRE

the stage, sometimes protected by an awning, being backed by a curtained structure that provided both a scenic background and a primitive *skene*. Unimportant as these stages may appear beside the permanent theatres, they represent a second basic actor-audience relationship. In the first (permanent theatre), the audience, seated on a slope, looks down on an actor before them (fig. 1); in the second (temporary stage) the actor, raised above a standing audience, can be seen and heard even by those at the rear of the crowd.

**The Roman Theatre.**—Like the Greeks the Romans had small temporary stages used by the players who performed in the mime; for some time the building of permanent theatres in Rome was banned, only temporary structures being used. The first permanent stone theatre was erected by Pompeius, 55–52 B.C. A temple was built here at the upper level of the *cavea*, and it has been suggested that this was a political move to overcome the restrictions on theatre building; it is now believed, however, that the remains of similar shrines can be discerned built into the colonnade—*porticus*—crowning other Roman theatres.

Most Roman theatres (fig. 4) were built on level sites with the tiers of seats supported on vaults enclosed within a massive wall. Both *cavea* and orchestra were semicircular; the entries to the latter were arched over so that the *cavea* merged with the stage buildings to form one unit. The stage was seldom more than five feet high and was connected to the orchestra by steps, suggesting that the orchestra was used by the actors; the orchestra also provided seating space for senators and guests. The stage buildings enclosed the stage on three sides to the full height of the *cavea*, the surrounding walls being richly decorated. There were usually three to five openings in the rear wall (*frons scaenae*) and one in each of the side walls. It is not known to what extent movable decorative scenery was used, but many theatres had a slot at the front of the stage into which a curtain could have dropped. The stage had a permanent timber roof; a covering (*velarium*) could be hung over the audience from the poles (masts) atop the upper part of the *cavea*. One of the theatres at Pompeii was built within a rectangular roofed structure.

Many structural remains of Roman theatres exist, but they are shorn of their luxurious trimmings. Examples can be seen in the theatre of Marcellus in Rome (23–13 B.C.); at Aspendus, Turk.; at Orange, France (c. A.D. 50); and at Verulamium (St. Albans), Eng. (2nd century A.D.).

**The Middle Ages.**—Knowledge of what dramatic experiences, if any, survived the disintegration of the Roman Empire is limited. By the 12th century, drama had gradually reemerged through the dramatization of church ritual. This form of drama developed its own method of presentation, with numerous stations (mansions) arranged around the body of the church, on or before which the various parts of the plays could be performed; the stations probably were decorated platforms that raised the actors above the congregation, who stood while viewing the drama. Later the performances were moved outside the church and were taken over by secular players, who, in England, were the members of the different guilds.

The plays were presented in two ways. The first was a direct development of the arrangement within the church: a series of mansions was set up around an open place, each mansion being decorated according to its particular function, as shown in a mid-15th-century engraving of the "Martyrdom of St. Apollonia" and in a 16th-century illustration of the Valenciennes mystery play. The former shows the main acting area as an open space around which the mansions were grouped, the action of the play passing between the open area and the individual mansions. This simultaneous arrangement of all the mansions around an acting area, sometimes termed a multiple setting, provided for many changes of scene by the simple expedient of moving the action from one locale to another. The audience is standing underneath the mansions, but it is possible that the artist has grouped the mansions more closely than they would in fact have been, and the audience may well have been accommodated in the spaces between. The "theatre" for these performances varied from the marketplace indicated in the illustrations to the Lucerne Passion Play (as it was performed in 1583) to the rounds at St. Just and Perranzabuloe, Cornwall, where earth and stone steps on banks surrounded a circular flat plain. That such a round may sometimes have been of a more temporary nature is suggested by wattle fence surround of the St. Apollonia engraving. In the second method of presentation the mansions were portable and were moved to different places in the town. The number of settings available was the same as in the multiple setting, but only one was visible at a time. These wheeled mansions were known as pageants and had a raised stage with a curtained area beneath as a room for the actors; no simple structures, they ranged from a realistic replica of Noah's ship to the fire-breathing mechanics of "Hell's mouth." The audience stood around this raised stage,

leaving space for the actors to perform, if necessary, at ground level. In some instances scaffolding was set up, presumably as seating for the important persons of the city or town, but no doubt nearby windows and balconies also were used.

**The Early Renaissance.**—In 15th-century Italy scholars and artists of the Renaissance created what they thought to be the correct settings for the recently discovered plays of ancient Greece and Rome; their work was based on an imperfect understanding of the descriptions of theatres and scenery by the Roman author Vitruvius. For particular occasions temporary stages were erected in the courtyards or halls of a duke's palace; descriptions suggest that the first attempts were similar to the stages illustrated in the edition of Terence's plays published in Lyons in 1493. These had a proscenium, or raised stage, hung with tapestries and backed by a scene front divided into compartments by richly decorated columns, the openings being curtained with cloth of gold. Each compartment of the scene front represented the home of the character named above the opening, and the interiors would seem to have been decorated to represent realistic scenes, an arrangement reminiscent both of the late Greek *thyromata* and the medieval mansions.

During the 16th century the study of perspective introduced a new medium of expression into the theatre and complicated what had been a comparatively simple actor-audience relationship by adding the glories of realistic scenery. The discovery that a scene of infinite grandeur could be realistically represented in a comparatively small space initiated the conflict as to the relative merits of spectacle and drama. In 1545 Sebastiano Serlio published in his *Architettura* a basic design for a theatre that clearly defined the three elements he considered essential (fig. 5): within a rectangular building he showed stepped seating (*gradines*) that was built on timber scaffolding around a semicircular orchestra. A raised rectangular stage extended the full width of the hall and was backed by a sloping stage on which was placed scenery that consisted of a number of two-faced panels painted to represent individual houses; these panels stood, like open books, on either side of a diminishing vista that led to a back panel or cloth.

**Permanent Renaissance Theatres.**—One of the earliest permanent theatres, as distinguished from the temporary structures erected for special occasions, is that designed by Andrea Palladio in 1580 for the Olympian Academy at Vicenza as an archaeological reconstruction for the revival of ancient plays (fig. 6). In this theatre Palladio created as perfect a representation of a Roman theatre beneath a roof as the restricted site and his knowledge allowed. The building was completed in 1585 by Vincenzo Scamozzi, when he added the model streets behind the doorways of the *frons scaenae*. These streets were constructed solidly of timber and plaster on a raking stage beneath a domed plaster sky and so arranged that each member of the audience could see into at least

one of them. This theatre is still used for a yearly festival of drama. The form of theatre developed for contemporary needs can be seen in the court theatre at Sabbioneta, Italy, designed by Scamozzi in 1588–90. This is a practical realization of Serlio's project, but the scenery was extended forward onto the *proscenae*, or actors' stage, to provide entry doors for the performers, who also used the floor of the hall (*orchestra*).

As yet the perspective scene had remained a permanent background. The possibilities inherent in a change of scene were soon realized, however, and gradually machinery was introduced that was capable of replacing the units making up a perspective scene with pieces representing a new vista; such scenic effects as the descent of gods and goddesses from the clouds and similar marvels now were possible. These effects would have been ruined if the machinery and mechanics had been visible to the audience, and so a frontispiece, or canvas frame, was added to hide the top and sides of the scene; the frontispiece later became a permanent architectural feature. Such an arrangement can be seen in the remains of the Teatro Farnese, Parma, Italy (1618–19), where the stage for scenery and machinery was contained behind an imposing frame (fig. 7). Although the performers used this area and its mechanical contrivances, they performed mainly in the orchestral area contained within the horseshoe *gradines*, which seated about 3,500 spectators. The perspective scene could be viewed correctly only from one point, and here was placed the personage in whose honour the spectacle was contrived. The entertainments provided in these courtly theatres were a mixture of music, song, spectacle, and drama, and they led eventually to the development of opera in Europe. These courtly functions also had a social significance, the spectacle of the audience being as important as that of the performers, a point that greatly influenced the auditorium form of the European court opera house.

Outside Italy courtly functions were more closely associated with the medieval form of theatre, as shown in an illustration of the Petit Bourbon, Paris, that appeared as the frontispiece to *Ballet comique de la reine* (1581). There the audience was seated around a rectangular dancing space, with the royal personages facing an embryonic stage that contained a small perspective vista. Further scenic elements were arranged, like mansions, at the side of the dancing floor. When members of the *Confrérie de la Passion* were permitted in 1548 to perform secular plays, they converted a rectangular hall in the Hôtel de Bourgogne, Paris, into a theatre; on the stage at one end all the different scenic items were arranged to form a *décor simultané*.

**Shakespearean Playhouses.**—In Tudor England actors performed in the halls of the great houses on the space before the paneled wall of the screens, using the doors for entrances and the gallery for upper scenes (see HALL). Both there and in the court masques the audience and any scenery probably were arranged in a manner similar to that at the Petit Bourbon, but in the later masques at Elizabeth I's court some scenery may well have been built on either the Terentian or Serlian model. Outside the court bands of players toured the guildhalls and the country houses or, like the Italian players of the *commedia dell'arte*, set up their trestle stage with its curtained backing in any available open space. As these players were by now professionals seeking remuneration, they preferred some enclosed area where an audience could be made to pay, and, like their colleagues of Spain and France, they chose the inns as one

FIG. 7.—PLAN OF THE TEATRO FARNESE, PARMA, 1618–19

FIG. 8.—JOHAN DE WITT'S DRAWING OF THE SWAN THEATRE, LONDON, ABOUT 1596. ONE OF THE FEW CONTEMPORARY SKETCHES OF THE ELIZABETHAN THEATRE

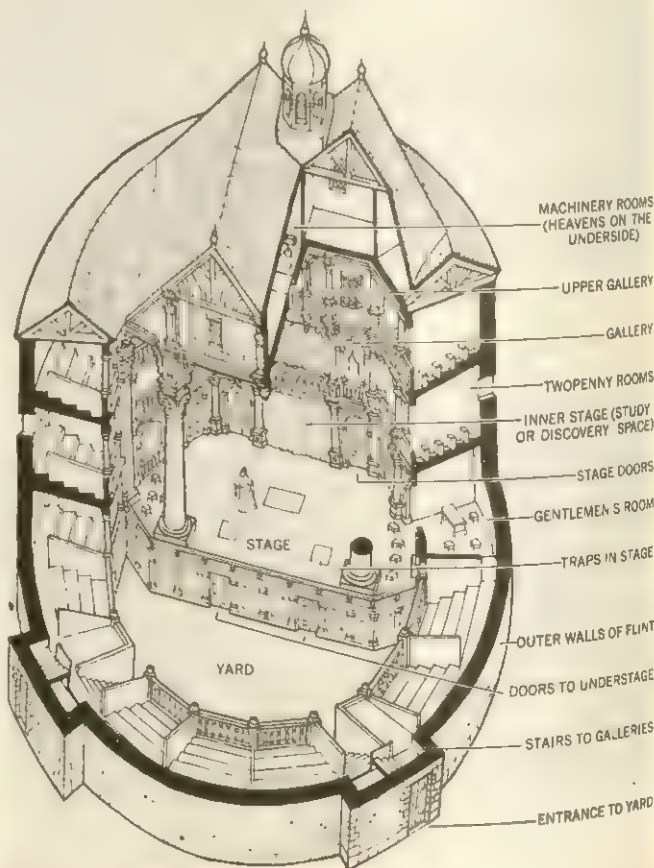

convenient centre, and bullbaiting and bearbaiting yards were also used.

When James Burbage built the Theatre in 1576, he probably based his ideas on these usual haunts, but visual evidence of the internal appearance of the early Elizabethan theatres is limited to one drawing of the Swan Theatre (fig. 8) that is copied from a sketch made by a Dutch visitor, Johan de Witt. This shows a raised rectangular stage or proscenium backed by the *mimorum aedes* ("the tiring house" or "house of the actors"), the front of which closely resembles the screens of the medieval halls with its two doors and balcony. Two classical columns supported a machine room over the stage, the underside being painted to represent the heavens from which gods would descend. The plays performed in these theatres suggest that there were traps in the stage and that items of scenery such as beds, tents, and trees were used. De Witt likens the Swan to a Roman theatre and describes it as being built externally of flint, with internal columns of timber painted to resemble the rich architecture of the Renaissance. Like the classical theatre before it the architectural stage provided the necessary entries and acting levels that convention could adopt to any imagined scenic need. The second Globe Theatre (1614) (fig. 9) is shown on a mid-17th-century map by W. Hollar to have been a circular building with a larger and more elaborate machine room than that at the Swan. Although no drawings showing the interior of these later theatres have survived, the texts of plays performed in them and the contracts for the Hope and Fortune theatres suggest that the front of the tiring house also had been altered and now contained a curtained inner room, an upper balcony, and doors of entry onto the stage. The admission price to the yard where the groundlings stood was 1d.; those wishing to be seated in one of the surrounding galleries could pay extra, and special rooms adjoining the stage were set aside for gentlemen, who also sat on the stage. The theatres were circular, or many-sided, with the exception of the square Fortune (1600), which was

80 ft. overall externally and, with the exception of the roofs over stage and galleries, open to the sky. In addition to these open theatres, there were also a number of covered theatres, but, apart from the fact that most were rectangular and fitted with boxes and a tiring house, little is known of their architecture.

At court the new scenic devices were being added to the masques by Inigo Jones, who had studied the Italian ideas and visited Vicenza. In 1605 Jones collaborated with Ben Jonson on the *Masque of Blackness*, for which he designed a permanent perspective background that was revealed by the fall of a painted curtain. When *Florimène* was produced in 1635, Jones built a stage that occupied nearly half the hall in front of the screens (fig. 10); the front scenes were fixed Serlian wings, but the back shutters were made so that they could be drawn aside to reveal further scenes. By 1640 Jones noted on his drawings for *Salmacida Spolia* that "ye scaene doe altogether change with ye back shutters."

**Restoration Playhouses.**—At the Restoration in 1660 some of the covered theatres that had survived the Puritan purge were reused. In addition, other theatres, such as the playhouse in Lincoln's Inn Fields (1661), were converted from existing tennis courts, which were rectangular roofed buildings similar to that at Hampton Court, but it was not long before new playhouses that were designed to permit the use of the new changeable scenery were built. The Dorset Gardens Theatre (1671), supposedly designed by Christopher Wren, is known, from the engravings in Elkanah Settle's *Empress of Morocco* (1673), to have had a rectangular stage (proscenium) that was flanked by the side walls of the auditorium and was entered through two doors on each side; boxes were built over the doors. Behind this proscenium area a tall opening framed a stage for perspective scenery, while above was a gallery with flanking openings. A contemporary description states that part of the audience was seated in the body of the hall (now called the pit), which was surrounded by two levels of seven boxes with a gallery above, the whole being elaborately decorated and lit by numerous candles.

FIG. 9.—CONJECTURAL RECONSTRUCTION OF THE SECOND GLOBE THEATRE, LONDON, 1614

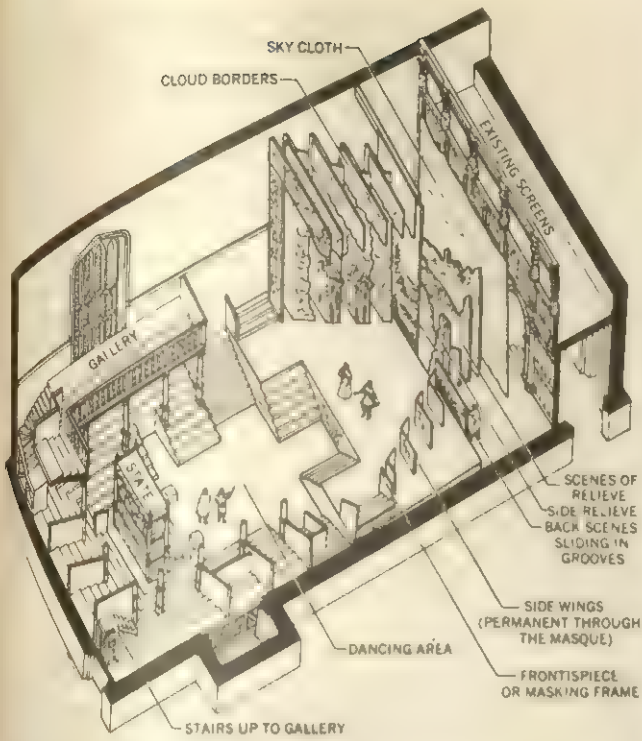

FIG. 10.—THE TUDOR HALL, WHITEHALL, ARRANGED BY INIGO JONES FOR THE MASQUE "FLORIMÈNE," 1635. CONJECTURAL RECONSTRUCTION BASED ON ORIGINAL DRAWINGS

Wren has also left a section that has been ascribed to the second Theatre Royal, Drury Lane, London (1674; fig. 11). Almost half of this 61 × 112 ft. building was occupied by a scenic stage and rooms for the actors, the remainder accommodating the auditorium with its stairs and approaches. In front of, and continuing, the sloping scenic stage was the proscenium, or actors' stage, about 20 ft. deep, which took up more than a third of the space in the auditorium and was approached on either side by two doors in each wall.

Before the proscenium was a stepped pit with benches, beyond which three curved amphitheatres faced the stage. The side walls of the fan-shaped auditorium, containing two tiers of boxes, were built in perspective to heighten the effect of the scenic illusion. By 1696 the management, wishing to increase the seating capacity, cut back the stage and replaced the lower doors of entry with boxes, thus commencing a movement that eventually pushed the actors back into the scenic area. Here they were finally surrounded in the early 19th century by a gilded picture frame, out of which they were forbidden to step.

**European Opera Houses.**—In Europe experiment still continued, and by 1693 Andrea Pozzo published a design for a theatre based on the visual requirements of the perspective scene. The auditorium had five semicircular tiers of boxes (loges) surrounding a flat area accommodating musicians and spectators. As a result of the need to accommodate large audiences, auditoriums evolved in which an elongated Farnese-type orchestra was surrounded by loges. Before long the side walls were inclined inward toward the stage so that a horseshoe plan resulted; this design was used in the majority of Italian opera theatres. Variations are found in the Bibiena theatres with their curved side walls, an arrangement that was vaguely reminiscent of the curved gradines at Sabbioneta, and in the ovoid plan seen in the Teatro la Fenice, Venice (1792). By the middle of the 18th century the flat orchestra had been replaced by a sloping floor with benches for the audience; the floor was separated from the stage by an enclosure for the large body of musicians necessary for opera and ballet. A typical theatre of this period is La Scala, Milan (1778; fig. 12A).

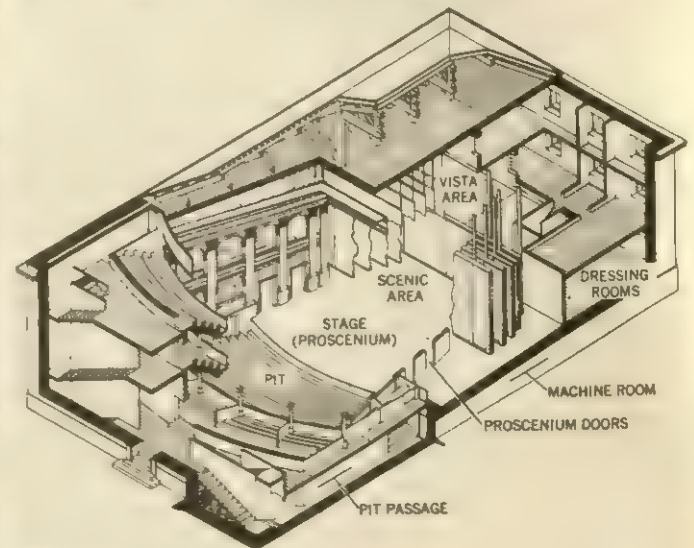

In France and England the rectangular and fan-shaped auditoriums continued in use throughout the 17th century. The adap-

tation of the Palais-Royal, Paris, by Vigarani in 1674 (earlier form built by J. Lemercier, 1637) and the design for the Comédie Française, Paris (1689), by F. d'Orbay (fig. 12B) both illustrate the manner in which the French plan compromised between the earlier rectangle and the new Italian ideas.

**Georgian Playhouses.**—During the 18th century the English playhouse became standardized in its units, but auditoriums varied between the fan shape seen at Covent Garden, London (1732; fig. 12C), the curved horseshoe in the Theatre Royal, Bristol (1766), and the plain rectangle of the small theatre at Richmond, Yorkshire (1788). The original scale drawings show that when Robert Adam amended Wren's Drury Lane in 1775 to increase its seating capacity, he retained the fan-shaped pit and the actors' stage within the auditorium but reduced the depth of this stage to about eight feet to accommodate additional pit benches and a musicians' pit. He also replaced Wren's side walls and boxes with a lighter structure, introduced an additional tier of boxes on either side, and increased the depth of the upper amphitheatre. This movement to increase the size of auditoriums was given further impetus when Henry Holland rebuilt the Theatre Royal in 1794 and designed a much larger building with five tiers of boxes and a deep upper gallery facing the stage. Similar increases in size were made when Covent Garden was rebuilt in 1792.

In addition to these large metropolitan theatres, smaller buildings were erected throughout the country; typical of these is the Richmond Theatre (fig. 13). Almost half of this 28 × 64 ft. building is occupied by a sloping stage, below which are a machine room and two dressing rooms. The remainder is taken up by the auditorium, small foyer, box office, and stairs. A 5-ft. portion of the stage is still within the auditorium; this portion is flanked by proscenium doors with boxes above them but is separated from the rectangular stepped pit by a small orchestra well; both pit and well are approached by a passage under the side boxes. The pit is enclosed by boxes; these are divided by low partitions and have side galleries above. A larger gallery faces the stage and extends over boxes and foyer beyond. Similar theatres were found in the majority of English towns and also in many of the major cities of the United States.

Famous among the latter structures are the Southwark Theatre (1766), the first permanent theatre in America, and the Chestnut Street Theatre (1794), both in Philadelphia; and the John Street Theatre (1767) and Burton's Playhouse (1848), both in New York City. By 1863 an engraving of Brougham's Lyceum Theatre, New York (1850), showed that the picture frame had replaced the proscenium stage and doors and that, as in England, the enclosing side boxes had been raised so that the pit could be extended beneath them. By this time the front benches in the pit were being replaced by more expensive orchestral stalls.

FIG. 11.—CHRISTOPHER WREN'S DESIGN FOR THE SECOND THEATRE ROYAL, DRURY LANE, LONDON, 1674. CONJECTURAL RECONSTRUCTION

FIG. 12.—17TH- AND 18TH-CENTURY THEATRES: (A) LA SCALA, MILAN, 1778; (B) COMÉDIE FRANÇAISE, PARIS, 1689; (C) COVENT GARDEN, LONDON, 1732

**Spectacles and Machines.**—At the Salle des Machines, Paris (1660), and throughout Europe, the uses of perspective scenery and machinery created ever more glorious spectacles, best illustrated in the 18th-century creations of F. Juvarra, G. B. Piranesi, and the Bibiena family. As a result, stages became larger, and the machinery, which became an integral part of the structures, became more intricate. A typical court theatre, complete with all its scenic marvels, can be seen at Drottningholm, Swed. (1764–66). The flat wings and shutters making up the scene could be easily changed because they were mounted on frames attached to carriages that ran on rails beneath the stage. In England these rails were replaced by a system of upper and lower scene grooves in which the scenery slid. The stage itself opened in many parts; this feature permitted the passage of scenes or of bridges carrying actors; cloths rolled up and borders were raised out of sight above the stage.

By the time J. L. C. Garnier designed the National Opera House, Paris (1875), the stage volume had swollen to enormous proportions that were conditioned not by the needs of the actor but by those of scene change. This building, designed on a monumental scale with its auditorium sunk within a shell of foyers, saloons, and stairs, was destined to set a style for many state theatres. Although English stages never reached these proportions, they nevertheless became standardized with a mezzanine and well into which the stage bridges and traps could sink, and with flying space above the stage and galleries from which the raising and lowering of the various pieces of scenery could be controlled (*see STAGE DESIGN*).

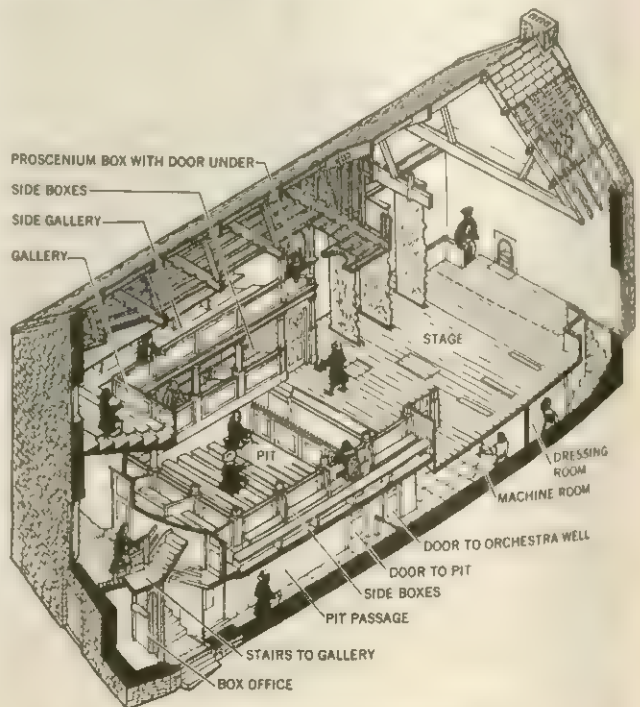

The new realism introduced into drama by mid-19th century eventually affected the scenery in that the wings, shutters, cloths, and borders were replaced by scenery that resembled real places as closely as possible. The old intricate stage machinery became largely redundant, but it was soon found that the new realistic scenery required even more complicated machinery if one elaborately built-up set was to be replaced rapidly by another.

**New Theatre Forms.**—European theatres of the late 19th century, besides being patronized by the court, were also subsidized by state or municipal authorities or by public subscription. These civic theatres had permanent companies that performed a repertoire of plays; the stock of scenery necessitated large stages, scene stores, and workshops. In England and the U.S. theatres were built by private owners who leased them for commercial profit to theatrical companies that performed only one play; storerooms, workshops, and large stages consequently were not considered essential; indeed, theatre designers sacrificed all other considerations to provide for a maximum audience at a minimum outlay. In the 20th century U.S. universities sponsored theatres on European lines, and civic repertory theatres appeared in Britain but on a small scale.

In 1876 the Wagner Theatre (Festspielhaus), Bayreuth, Ger (fig. 14), was constructed to provide the correct atmosphere for Wagnerian operas. This design broke away from the standard horseshoe auditorium with its individual privately rented loges and developed an auditorium with no social distinctions. Fan-shaped in plan, the auditorium had 31 widely spaced rows of seats which were entered at the ends and arranged in a single-slope fashion reminiscent of a Greek theatre. Max Littmann used a similar design for his Prinzregententheater (Prince Regent Theatre), Munich (1901), seating 1,106; the seating of his Künstlertheater, Munich (1908; fig. 15), was also designed with one constant rise of steps from front to rear, but the auditorium was rectangular. In later practice the auditorium floor follows a parabolic curve, with the rear seats rising more steeply than those at the front.

English architects became aware that the actor was no longer on a stage within the auditorium and modified their designs so that the majority of the audience faced the stage, although stage boxes were retained. Unlike the one-tier German examples, these English theatres had several deep balconies across the full width of the auditorium, an arrangement made possible by the use of iron and steel cantilever construction. Maximum audiences were packed into these shelves in narrow rows of seats, which were divided by access aisles.

While the European sponsored theatres were, for the most part, built on open sites, theatres in the United States and Great Britain were built on expensive restricted sites in built-up areas, so that the foyers, vestibules, cloakrooms, and provision for actors and stage staffs were more restricted and not so well equipped as their European counterparts. A typical British example of 1897 was Her Majesty's Theatre, London, which seated 1,319. In the United States Booth's Theatre, New York (1869), was similar to Her Majesty's, and a later version of this auditorium form is the Ziegfeld Theatre, New York (1927), a large theatre designed for spectacular musicals. The Little Theatre, New York (1912; fig. 16A), which seated 299, approximated in its planning the Littmann theatres but on a smaller scale. The outline plan and section that became standard for picture-frame theatres are well illustrated by the Guild Theatre, New York (1925; fig. 17), while later practice can be seen in the Oberlin (O.) College Theatre (1952; fig. 18), with its internal form designed to provide correct acoustical and lighting conditions.

FROM H. AND H. LEACROFT, "THE THEATRE"

FIG. 13.—THE GEORGIAN THEATRE AT RICHMOND, YORKSHIRE, 1769

The introduction of gas for lighting in the early 19th century had permitted the darkening of the auditorium during a performance; the addition of electric light in the early 20th century allowed more realistic stage effects to be achieved. The ideas of Adolphe Appia, Adolph Linnebach, and Mariano Fortuny led to the introduction of the cyclorama, or sky dome, which, when evenly lit, simulated the sky and provided an enclosure within which three-dimensional scenery could be set; this style of presen-

FIG. 14.—PLAN OF THE FESTSPIELHAUS AT BAYREUTH; GOTTFRIED SEMPER, ARCHITECT

tation developed into the space stage, or performance in an apparently infinite setting.

At the Schauspielhaus, Dresden (1913; fig. 19), the complete enclosing of the stage prevented the horizontal moving of scenery at stage level, so hydraulic lowering and lifting devices were installed to lower stage sections to the basement level, where they could be replaced by other sections that had been preset with scenery in the side assembly areas. One of the earliest uses of such hydraulic lifts was in the National Opera House, Budapest (1884).

At the Volksbühne, Berlin (1914; fig. 16B), the structural cyclorama, enclosing a revolving stage, was cut back to permit horizontal movement of scenery at stage level. All these cycloramas were cut back at the top to permit vertical movement of scenery into the stage tower.

**A Return to First Principles.**—As early as the mid-19th century some theatre workers felt drama to be more important than spectacle and numerous attempts were made to design theatres that permitted a return to the simple actor-audience relationship by constructing what were thought to be Elizabethan stages. In 1840 Karl Immermann designed such a stage in Düsseldorf, although this was more like a Roman stage with an enlarged central doorway forming an inner stage.

In the early 20th century William Poel in England and Max Kruger in Germany produced Shakespearean plays in reconstructions of Elizabethan theatres based on the De Witt drawing of the Swan (discovered in 1888). Further notable reconstructions

FROM LITTMANN, "DAS MÜNCHENER KÜNSTLER THEATER"

FIG. 15.—SECTION OF KÜNSTLERTHEATER AT MUNICH; MAX LITTMANN, ARCHITECT

of Elizabethan theatres were the Maddermarket Theatre, Norwich (1921), the first Mermaid Theatre, London (1951), and the Festival Theatre, Ashland, Ore. (1959).

The idea of a permanent architectural stage for modern productions was given expression by Louis Jouvet and Jacques Copeau in 1920 at their Théâtre du Vieux Colombier, Paris. This had a permanent inner stage and balcony with stairs connecting to the main stage; there was no picture frame to separate the audience from the stage. Before long, however, attempts were made to disguise the permanent setting and suggest some verisimilitude in the scenes; but these attempts only served to emphasize the limiting nature of the permanent structure if used for any other than conventional purposes. A similar, although simpler, arrangement is to be seen in the Mermaid Theatre, Puddle Dock, London (1959).

**Open Stages.**—The idea that the actor could again step out of the picture frame was slowly gaining ground. Max Reinhardt staged productions in circus buildings and exhibition halls, and his Grosses Schauspielhaus, Berlin (1919), combined a normal stage with a revolve (revolving stage) and cyclorama; the stage connected through a nonexistent proscenium opening and an adaptable (adjustable) forestage with an arena stage that was surrounded by a horseshoe of seating. Here Reinhardt combined spectacular settings on the main stage with crowds in the arena, a type of production suited to the size of the theatre, but the individual actor was lost in the spacious arena.

In the civic theatre at Malmö, Swed. (1944), the auditorium, like many late 19th-century opera houses used also for drama, was designed so that its size and shape could be altered by moving screens. The projecting stage could be replaced by seating, and the width and height of the proscenium opening could be varied. The stage was equipped with a tower for flying scenery, a revolve,

and movable trucks; there also were workshops where scenery could be constructed and assembled. The planning difficulties inherent in the dual focus of the Grosses Schauspielhaus and the lack of intimacy between the individual actor and his audience were overcome in a later example designed by Marcel Breuer for Sarah Lawrence College, Bronxville, N.Y. (1952; fig. 20); this structure seats 500.

A completely open-stage version of this form of theatre is that at Stratford, Ont. (1957), where the picture-frame stage is entirely dispensed with, and the acting area, contained in a horseshoe auditorium, is surrounded on three sides by 2,258 seats arranged on two levels. This theatre was patterned after Tyrone Guthrie's open-stage productions in the Assembly Hall, Edinburgh, and after John English's tented Arena Theatre, Birmingham, Eng. (1948).

An earlier version of such a single-hall arena theatre was the project for the Meyerhold Theatre, Moscow (1925), where an arena stage, equipped with two revolves, was enclosed by a single horseshoe tier of seating. Open stages that permit the use of built and projected scenery and are situated within the auditorium can be seen in the Kalita Humphreys Theatre, Dallas, Tex. (1959), and in the Community Theatre at Western Springs, Ill. (1960-61), while the small single hall of the Waco Community Theatre (1958) can be used for a wide variety of actor-audience relationships.

**Picture Frames and Forestages.**—In London and New York City and other metropolitan centres stringent fire regulations, which resulted from numerous disastrous fires caused by naked

flames of the oil lamp and gas eras, require that it must be possible to cut off the stage from the auditorium in case of fire; all openings in the wall that separate the two parts of the standard picture-frame theatre, normally called the proscenium wall, must be capable of being closed by a fire-resisting curtain or doors. These limitations controlled attempts to bring the actor out of the picture frame—except in the very smallest theatres—and in the majority of theatres built during the 20th century the status quo of the picture-frame stage was maintained, except for such limited deviations as the replacement of the gilded picture frame by an adjustable proscenium opening and the addition of a small fore, or apron, stage that was built into the auditorium. The Coburg Theatre, London (1818), later known as the Old Vic, was adapted in this manner in 1950. The Royal Shakespeare Theatre, Stratford-upon-Avon (1932), seating 1,000, was designed with a deep proscenium frame that contained a removable forestage, with steps to the auditorium; the forestage was flanked by two units topped by balconies and containing side doors. This arrangement did not work well in practice, and these features were later removed so that the main stage could be advanced closer to the audience. The fan-shaped auditorium has a circle and gallery, but the audience seated there felt too remote from the stage, a criticism later amended by the introduction of side boxes that step down toward the stage. A similar arrangement is incorporated in the auditorium of the civic Belgrade Theatre, Coventry (1958), seating 910. Externally these two theatres, like that at Malmö, are designed to express their internal form, the fenestration of the main facades expressing the open character of the lounges, restaurants, and foyers.

**Arena and Flexible Stages.**—In the Realistic Theatre, Moscow, the actor-audience relationship was altered to suit each individual production during 1932–38. N. Okhlopkov's production of *Mother* used a raised platform around the walls of the hall, with steps leading from each side to a central circular platform; the audience was seated in the intervening spaces. This form of arena theatre, or theatre in the round, had been tried in the U.S. at Columbia University in 1914 and was later developed as an economic theatre form.

Other examples of arena theatres include the Penthouse Theatre, University of Washington, Seattle (1940); the Playhouse Theatre, Houston, Tex. (1950), seating 306; the Théâtre en Rond, Paris (1954); and the Teatro Sant'Erasmo, Milan (1953), seating 250. In most of these theatres the acting areas at floor level are circular, oval, trapezoid, or rectangular, with the audience seated on all sides; in the Teatro Sant'Erasmo, however, the audience is in two blocks located on opposite sides of an octagonal acting area, with scenic access on the remaining sides.

A more flexible form of theatre is the one located at the University of Miami, Fla. (1950), seating 400–900, where the actors and audience may be arranged in any one of three open-stage variations: in the round, with a three-sided platform, or with an end stage.

These forms of theatre present a new problem to the architect in the placing of lighting equipment and the use of acoustic forms that permit an actor to be heard behind him as well as in front. This problem, together with the demand for a more intimate actor-audience relationship, may perhaps necessitate a restriction on the size of auditoriums. Spectacle theatres may be large, but theatres designed for actors should be intimate; the actor should not be forced to adopt exaggerated gestures and vocal gymnastics in order

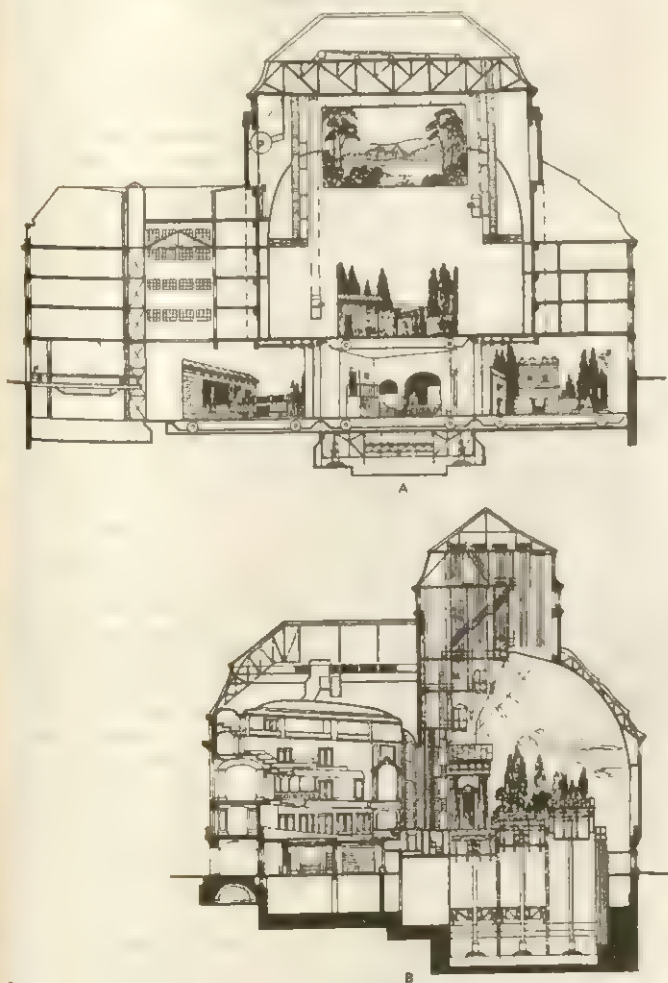

FIG. 20.—SARAH LAWRENCE COLLEGE THEATRE: MARCEL BREUER, ARCHITECT. UPPER FLOOR PLAN

to make himself understood in the far recesses of some huge structure.

The National Theatre, Mannheim (1957), is an example of the trend in theatre design—seen at Malmö—where two theatres are provided; the larger theatre at Mannheim is designed as an opera house seating 1,200 in one large pit, a small balcony and side boxes. Like so many of the new and rebuilt municipal theatres of Europe—Cologne (1957), Vienna Opera House (1955), and Vienna Burgtheater (1955)—the Mannheim theatre follows the normal picture-stage arrangement, with an auditorium designed for acoustics and lighting and a stage lavishly equipped with the most modern mechanical and lighting devices. The smaller theatre at Mannheim is arranged so that it may be used as a picture-frame theatre with or without a forestage, seating 606; as a lecture or concert hall, seating 870; or as an arena theatre similar to the Sant'Erasmo, Milan, seating 680. Various attempts were made to design flexible theatres capable of providing all these differing forms and for increasing audience participation in the scenic production. Such a theatre is exemplified in the project for a "total" theatre designed by Walter Gropius in 1927 (fig. 21). Here the auditorium, consisting of a single bank of seating facing a fully equipped stage backed by a cyclorama, is completely surrounded by a narrow stage backed by screens onto which motion pictures could be projected as scenery. By revolving a portion of the seating, a form of theatre in the round resulted. The idea of enclosing the audience by stages has formed the basis of many projects, notably Oskar Strnad's "Ringbühne" (1923). An example may be seen in Studio One, Baylor University, Tex. (1941), where three stages enclose a rectangular audience area that may also be used as the stage of an arena theatre. A project that attempts to combine all the different theatrical forms in one building on a more intimate scale is the Questors Theatre, Ealing, London (1964), seating approximately 350.

In the Loeb Drama Centre at Harvard University (1959–60) the seating may be rearranged by the use of electrical devices, so that the theatre may be used with a picture stage, a three-sided open stage, or as a theatre in the round. This building also contains an experimental studio in which any actor-audience relationship may be established.

It was perhaps inevitable that attempts would be made to combine the new actor-audience relationship with the spectacular use of light and scenery, and as early as 1922 Norman Bel Geddes designed the project Theater #14 (fig. 22). The acting area was separated from the audience by a pit from which the actors ascended to the stage. The stage itself sank into a basement, where preset scenery could be moved onto it, the attention of the audi-

ence being meanwhile distracted by upward shafts of light from the well. Lighting was arranged in the ceiling of the auditorium, which was designed as an enclosing cyclorama.

**Multiple-Use Theatres.**—A difficulty of theatre design caused by economic competition is that of making a theatre pay for itself although it is used only a few hours each day. After 1938 the commercial U.S. theatre, and later the British, attempted to solve this problem by building new theatres in a block of shops, offices, or similar commercial developments, but the answer probably lies in developing theatrical activities in a manner that makes it possible to use the building(s) for differing functions throughout the day. U.S. university and community theatres have had to be built to provide for diverse uses; e.g., the Speech Arts Building, Orange Coast College, Costa Mesa, Calif. (1955); and the Midland (Tex.) Community Theatre (1957), whose open stage permits the use of the auditorium for a wide variety of purposes.

In Europe national theatres combine halls for drama, opera, and concert within one building. The 18th- and 19th-century convention of adapting a theatre for balls by placing temporary flooring over the pit at stage level, as is done at Covent Garden Opera House, London, the Opera House, Vienna, and elsewhere, was replaced in the Corso Theatre, Zürich (1934), by an adaptable auditorium floor. In the Lincoln Center for the Performing Arts, New York, provision is made for drama, opera, music, and dance in separate buildings grouped to form one cultural centre.

(R. V. B. L.)

**THEBES**, one of the most famed cities of antiquity, the capital of the ancient Egyptian empire at its heyday, lay on either side of the Nile at approximately latitude 26° N.; the modern town of Luxor, which occupies part of the site, is 419 mi. S. of Cairo. Ancient Thebes was about six miles square; modern Luxor

and Karnak on the east bank contained the city of the living and the great temples of the imperial cult, while on the west bank were the royal necropolis, the kings' mortuary temples and the houses of those priests, soldiers, craftsmen and labourers who were devoted to their service.

The ancient name of Thebes, Wase or Wo'se, was derived from the sacred was-sceptre. The nome or province of Wase, the fourth of upper Egypt, is known to have existed from the 4th dynasty onward; the capital was at first Hermonthis, Thebes itself being still a small village. The first monuments that have survived there date from the 11th dynasty, when the local nomarchs fought the Herakleopolitans and eventually reunited Egypt under their rule. From this time Thebes, the new capital, became Nowe or Nuwe "the City (of Amon)," in Hebrew No-Amon. The Greeks named the city after their own Thebes (Thebai), from the name of Luxor, Ta-o-pe, or, on occasion, Diospolis Magna.

During the 12th dynasty the residence was moved to Al Fayyum, but the kings of Egypt honoured Amon, their family god, and built temples in the area. The Hyksos had little or no control over the nomarchs of Thebes, the last of whom assumed royal titles; kings of Thebes in the 17th dynasty won successive victories against the invaders and their Nubian allies, and finally freed and reunited the country. Then began the era of greatest prosperity for Thebes. The 18th-dynasty Pharaohs made it their capital, built a new city and enlarged and partly rebuilt the great temples of the triad of Thebes: Amon, his consort Mut, and their son Khonsu, the moon-god. They embellished their temples with the spoils of Asia and the tribute of Nubia. During the 19th century B.C. great palaces rose on either bank of the river, brightly painted and surrounded with gardens; noblemen had their estates round about, and in the crowded streets foreign traders and mercenaries mingled with the citizens. The Pharaohs of the New Kingdom vied with each other in building great temples on the east bank and even larger mortuary temples on the west. The height of Theban prosperity was reached about 1400 B.C. in the reign of Amenhotep III, much of whose vast wealth from foreign tribute was poured into the temples of Amon. For a brief period in the reign of his son Ikhnaton (*q.v.*) Thebes fell on evil times; the city was abandoned by the court and the worship of Amon proscribed, but with the restoration by Tutankhamen Thebes soon regained its revenues and its prestige and retained both through the reign of Seti I and Ramses II who still resided for part of every year in Thebes. The city continued to be richly endowed, and a remarkable document known as the great Harris papyrus states that Ramses III donated 86,486 slaves and vast estates to Amon's temples.

Under the later Ramessids Thebes began to decline; the government fell, it seems, into grave economic difficulties and in the reign of Ramses IX, about 1120 B.C., a series of investigations into the plundering of royal tombs in the necropolis of western Thebes uncovered proof of corruption in high places, following an accusation made by the mayor of the east bank against his colleague on the west. The plundered royal mummies were moved from place to place and at last deposited in the tomb of Amenhotep II and in the burial place of the priest-kings at Dayr al Bahri; the finding of these two hiding places was one of the great events of archaeological discovery. Maladministration led to unrest and there were strikes among the necropolis workers.

Control of local affairs tended to come more and more into the hands of the high priests of Amon and led to a situation in which, after the death of the last Ramses, the government of Egypt was shared between the Pharaoh in Tanis and the high pontiff at Thebes. Intermarriage and adoption strengthened the ties between them, daughters of the Tanite kings being installed as "God's Wife of Amon" at Thebes, where they wielded great power.

The Napatan (Ethiopian) Pharaohs made Thebes their capital. Its fame among the early Greeks was such that Homer speaks of the wealth of "hundred-gated Thebes." In 661 B.C., however, it was sacked by Ashurbanipal's Assyrians, and although rebuilt by the Saïtes it never recovered. In the later Persian wars it again suffered. It may have been at the very end of the dynastic period that hundreds of statues from the temple were collected together and buried in a pit, where G. Legrain found them in 1903. In Strabo's time (c. 63 B.C.—c. A.D. 21) the city had dwindled to a mere village visited by tourists who came to see the ruins.

### LUXOR AND KARNAK

**The Temples of Karnak.**—Karnak, on the east bank of the Nile, is a village which has given its name to the most northerly part of Thebes, the quarter in which the great temples of Amon, Mut and Khonsu were situated. Its ancient name was Ipet-isut, or Eptesowe, "Chosen of Places." The ruins of Karnak cover a considerable area and are still impressive, though nothing remains of the houses, palaces and gardens that must have surrounded the temple precinct in ancient times. The temples are enclosed within three enceinte walls. The most northerly is that of the temple of Month, the war-god, of which little now remains but the foundations. The southern temple is that of the goddess Mut, wife of Amon; this also is much ruined. It was built largely by Amenhotep III, whose architect was commemorated by statues in the temple, and has a horseshoe-shaped sacred lake.

Between these two precincts lay the largest of all Egyptian temples, and one of the largest in the world, the great metropolitan temple of the state god, Amon-Re. It is in fact not one temple but a complex of temples, at many periods added to and altered, and lacking in consequence a coherent plan. It has been called a great historical document in stone. In it are reflected the fluctuating fortunes of the Egyptian empire. There are no fewer than ten pylons, separated by courts and halls, and nowadays numbered for convenience from west to east, no. 1 being the latest; the seventh and eighth, erected by Thutmose III and

FIG. 1.—THEBES, EAST AND WEST BANKS

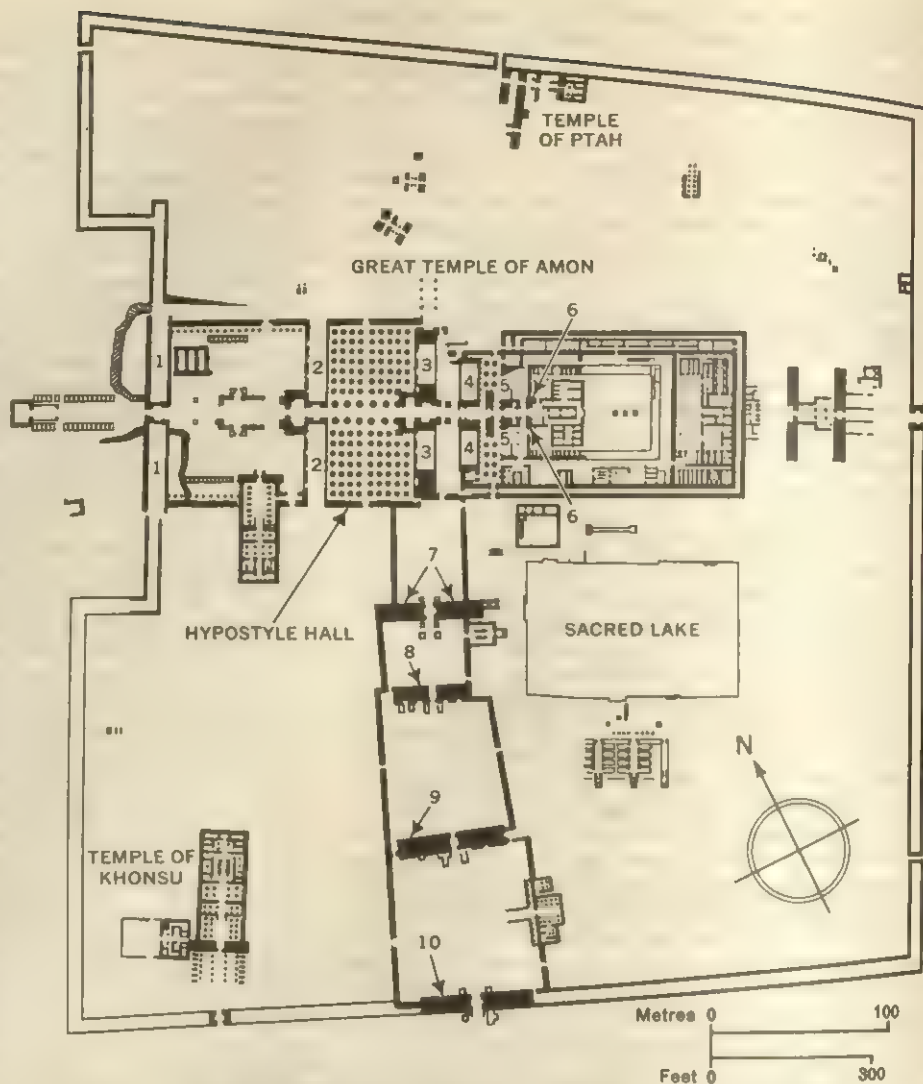

Queen Hatshepsut, and the ninth and tenth, of Horemheb's reign, formed a series of processional gateways at right angles to the main axis, linking the temple with that of Mut to the south, and further by way of the avenue of sphinxes, with the temple of Luxor two miles away.

The history of the temple must be briefly sketched. The original Middle Kingdom temple has left no trace save a small jubilee shrine of Sesostri's (Senusret) I, now reconstructed from fragments found inside the third pylon. At the beginning of the 18th dynasty Thutmose I enclosed the 12th-dynasty temple and fronted it with two pylons, the fifth and fourth, with a hypostyle hall of gilded cedarwood between. Hatshepsut pierced the roof with two tall obelisks, one of which still stands. In the reign of Thutmose III the temple was greatly enlarged; not only did he add to the existing structures and add a pylon and pillared courts containing halls in which he inscribed the annals of his campaigns, but he also built to the east of the Middle Kingdom area a transverse temple in the form of a jubilee pavilion; on the walls of one of the rear rooms is carved a kind of pictorial catalogue of the strange animals and plants he had brought home from Asia in the 25th year of his reign. He was probably also the builder of the wall which runs round the temple from the fourth pylon eastward, and of the sacred lake to the south of it, on which the barque of Amon floated. Small additions were made by his successors, and Amenhotep III added a pylon (no. 3) to the west and greatly embellished the temple.

The most striking feature of the temple of Karnak is the hypostyle or pillared hall which occupies the space between the third pylon and the second, built by Ramses I and Horemheb. The area of this vast hall, one of the wonders of antiquity, is 5,800 sq. yd. It was decorated by Seti I and Ramses II, to whom much of the construction must be due, but may have been planned and begun earlier. Fourteen enormous columns, 78 ft. high, raised the roofing slabs of the central nave above the level of the rest so that light and air could enter through a clerestory. Seven lateral aisles on either side brought the number of pillars to 140. Historical reliefs on the outer walls show the victories of Seti in Palestine and Ramses II defeating the Hittites at the battle of Kadesh.

Ramses III built a small temple to Amon outside the Ramesside pylon and at right angles to it, confronting a triple shrine erected by Seti II. The Bubastite kings of the 22nd dynasty, in adding a vast court to the front of the temple, incorporated both these small temples. The Bubastite gate at the southeast corner of this court commemorates the victories won by Sheshonk (*q.v.*) I, the biblical Shishak, in Palestine in the reign of Rehoboam. The Napatan Pharaoh Taharqa planned a tall colonnade of which one pillar still stands, and perhaps began the giant first pylon, 370 ft. wide and 143 ft. high, which was continued by one of the Ptolemies but never completed. Beyond it, an avenue of sphinxes dating from Ramses II's reign leads to the quayside.

Within the enclosure of the great temple of Amon-Re are in-

ADAPTED FROM W. S. SMITH, "ART AND ARCHITECTURE OF ANCIENT EGYPT"; REPRODUCED BY PERMISSION OF PENGUIN BOOKS  
FIG. 2.—THE TEMPLE OF KARNAK. NUMBERS REFER TO PYLONS

cluded a number of other small shrines and temples. A temple to Ptah and Hathor, in the north side of the enclosure, was built by Hatshepsut and Thutmose III and added to by the Ptolemies, who also embellished the great temple by the addition of granite shrines and gateways. To the south, Ramses III dedicated a temple to Khonsu, the moon-god, which merits attention. A small late temple to Opet, the hippopotamus goddess, adjoins it.

Karnak presents a continual problem to the architects who seek to preserve it, for the foundations are inadequate and moisture from the inundation has disintegrated the sandstone at the base of walls and columns. The work of repairing and strengthening goes on continuously, and in carrying out this work new discoveries are constantly being made. In one of the pylons, thousands of fragments from the destroyed temple of the Aton at Thebes were found.

**The Temple of Luxor.**—The southern part of Thebes grew up round the other great temple of Amon. Ope or Ipet, "the Harim (of Amon)." The modern name, in Arabic al Uqsir, means "the palaces" or perhaps, after the Roman *castra* remains of which have been found in the neighbourhood, "the forts." Here, close to the Nile and parallel with the bank of the river, King Amenhotep III built his beautiful temple dedicated to Amon-Re, king of the gods, his consort Mut and their son Khonsu.

A small pavilion is all that is left of earlier work, though there was probably a temple here earlier in the 18th dynasty if not before. It was completed by Tutankhamen and Horemheb and added to by Ramses II; smaller additions were made in Ptolemaic times, and the hypostyle hall was at one time converted into a

Christian church; remains of another Coptic church can be seen to the west of it.

The original part of the temple consisted of a large peristyle court and a complex of halls and chambers beyond; on the east side of the central hall was the birth room, a chapel whose walls were decorated with scenes of the mystical marriage of Queen Mutemuia, Amenhotep's mother, with the god Amon and of the birth of the royal child with the assistance of goddesses. One of the halls contains a granite shrine of Alexander the Great.

The great court is surrounded on three sides by a double row of graceful papyrus-cluster columns, their capitals imitating the umbels of papyrus in bud. An entrance flanked by the towers of a pylon was planned for the north end, but this design was altered and, instead, the most striking feature of the temple, a majestic colonnade of 14 pillars, 52 ft. high, was added. The capitals imitate the open single umbels of papyrus. It may have been intended for the central nave of a hypostyle hall similar to that at Karnak, but the side aisles were not built; instead, enclosing walls were built down either side. Ramses II added an outer court, decorated with colossal statues of himself between the pillars of a double colonnade, and a lofty pylon on which he depicted festival scenes and episodes from his wars in Syria. In front of the pylon were colossi and a pair of obelisks, one of which still stands; the other was removed in 1831 and re-erected in the Place de la Concorde in Paris.

In the forecourt of the temple is the mosque of Sheikh Yusuf al-Haggag, the local Muslim saint. His feast is celebrated with a boat procession which recalls the "Beautiful Festival of Ope" during which, on the 19th day of the second month, Amon came from Karnak on his state barge to visit his other temple at Luxor, escorted by the people of Thebes in holiday attire. Reliefs on the walls of the great colonnade depict preparations for the procession of sacred barques during the festival.

#### WESTERN THEBES

Across the Nile from Luxor and Karnak, on the western bank, there was another Thebes, the abode of the dead. The Egyptians called the whole region the Western City, or Kheftet-her-nebes, "She who is opposite to her lord." In Greco-Roman and Coptic times it was called Djeme. The presiding deity was a goddess, Mert-Seger, "the Lover of Silence," who lived on the peak which dominates the range of cliffs in which the tombs are hollowed. On death, both Pharaohs and commoners were ferried across the river to be buried in the necropolis of the west. The earliest cemeteries are in the most northerly part of the area; nomarchs named Intef of the early 11th dynasty built pyramid tombs on the desert edge north of the present village of Qurnah, where the cliffs approach most nearly to the river, and their successors, the Mentuhoteps who ruled the whole country, had larger tombs farther to the south; the largest, that of Mentuhotep II, was built at the head of the valley of Asasif, at a spot known as Dayr al Bahri, "the northern monastery." Here, dwarfed by a semicircle of towering cliffs, he built a combined pyramid tomb and funerary temple on three ascending terraces.

**The Valley of The Tombs of the Kings.**—The kings of the New Kingdom, fearing for the safety of their rich burials, adopted a new plan, that of building only their mortuary temples in the low desert within view of the valley, and concealing their tombs in a lonely valley (Biban al Moluk) in the western hills behind Dayr al Bahri. Here, in tombs sunk deep into the heart of the mountain, the Pharaohs of the 18th, 19th and 20th dynasties from Thutmose I onward were interred, and also one or two queens and officials of high rank. The plan of the tombs varies considerably but consists essentially of a series of descending corridors, interrupted by deep shafts to baffle robbers and by pillared chambers or vestibules; at the farther end is the burial chamber with a stone sarcophagus in which the royal mummy was laid, and store chambers around which furniture and equipment were stacked for the king's use in the next world. The walls were in many cases covered with sculptured and painted scenes depicting the dead king in the presence of deities, especially the gods of the underworld, and with illustrated magical texts similar to those found in funer-

ary papyri, designed to help him on his journey through the nether regions. There were a number of these texts; they represent differing, but not necessarily conflicting, views of the afterlife in which the king had to undergo trials and surmount perils. In the *Book of That Which Is in the Underworld*, for instance, he travels in the boat of the sun-god through 12 caverns which represent the 12 hours of the night. In the *Book of Gates* giant serpents guard the portals through which the sun has to pass, and strange genii and demons help or hinder the boat on its way. Astronomical figures often decorated the ceiling, and the sky-goddess Nut herself is painted across the firmament of stars.

There are some 60 tombs in the valley, almost all of which were robbed in antiquity, many of them during the lifetime of the successors or of near descendants of the owners. In the time of Strabo, Greek visitors were able to visit 40. Only the little tomb of Tutankhamen (*q.v.*) on the floor of the valley, protected by a pile of rock chippings thrown down from a later, Ramessid, tomb, escaped pillage. Those fortunate enough to have seen the wonderful treasures in the Tutankhamen galleries of the Cairo museum will realize how rich the burial of a great Pharaoh of the empire's heyday must have been. The longest tomb is no. 20, that of Queen Hatshepsut (*q.v.*), whose burial chamber is nearly 700 ft. from the entrance and descends 320 ft. into the rock.

In the 19th and 20th dynasties, queens and a few favoured royal princes were buried in another valley today known as Biban al Harim, "the Valley of the Tombs of the Queens." It is situated at the southern end of the Theban necropolis, about 1½ mi. W. of the temple of Medinet Habu. Here over 70 tombs have been found, very few of them inscribed and decorated. The earliest may be that of Sitre, wife of Ramses I. Those most worth visiting are the tomb of Nefertari (no. 66), the favourite queen of Ramses II, of Prince Khaemwese (no. 44) and Prince Amonhirkhopshef (no. 55), and of a Ramessid queen called Titi (no. 52).

**The Tombs of the Nobles.**—The limestone foothills which lie parallel to the river and about three miles away from it are honeycombed for a distance of over two miles with the tombs and tomb-chapels of high officials, mainly of the 18th, 19th and 20th dynasties. The usual plan of these tombs was a forecourt, a transverse chamber, a long corridorlike room and, at the end, a chapel containing statues of the deceased and his family, in the floor of which a shaft or passage ran down to the burial chamber. After the funeral the shaft was filled in but the chapel and anterooms were kept open and visited by the family of the tomb owner. Near the villages of Dira 'Abu'l Nega', Al Asasif, Al Khokha, Shaykh Abd al-Qurnah, Dayr al Medina and Qurnat Mura'i, several hundred tomb-chapels are still open to view. The walls are decorated with mural paintings, many of them wonderfully fresh and full of vivid interest, depicting the daily occupations of the ancient Egyptians. The dead are shown, in the outer rooms of these tombs, inspecting the workmen on their estates, or in their hours of leisure hunting birds in the marshes, or game in the desert, listening to music or playing checkers with their wives. In the infinite variety of these homely scenes, the whole cycle of the farmer's year, from plowing to harvest, is depicted; sculptors, metalworkers, weavers and brickmakers ply their trades; and butcher, brewers and cooks prepare food for the dead man's table. The treasurer goes on his rounds of inspection and the vizier receives foreign envoys to Pharaoh's court. The gay patterns on the roofs derive from those in houses of the period. In the inner chapels, fewer secular scenes are found. The funeral ritual is usually depicted: the cortège crossing the Nile, the ceremony of "Opening the Mouth" by the tomb door, the funerary feast; while in the innermost chamber there are representations of the deceased man and his wife in the company of Osiris and other gods, undergoing the ordeal of judgment known as the "weighing of the heart" or being given nourishment by the goddess in the sacred sycamore. In the tombs of the late New Kingdom, purely religious scenes predominate.

**The Royal Mortuary Temples.**—In the New Kingdom, when the Pharaohs hid their tombs in the secret valley, ostentation had to be concentrated in their mortuary temples, which rivaled each other in size and magnificence. Although they were designed for the performance of rites connected with the mortu-

ary cult of the builder, they were all dedicated to Amon, the supreme god of Thebes, and had the character and essential form of a New Kingdom temple. They were built in western Thebes on the edge of the valley, in a sequence generally corresponding to a topographical arrangement from north to south. Only traces of most of the earlier ones remain. The most important will be mentioned here.

1. The temple of Hatshepsut at Dayr al Bahri, which is the earliest large 18th-dynasty structure to survive and one of the most impressive. Here in the bay of cliffs, next to the pyramid-temple of Mentuhotep II mentioned above, the queen's architect Senenmut in about 1490 B.C. designed a series of colonnades and courts on three levels. The approach from the valley led through an avenue of sphinxes, and in the forecourt was a garden planted with trees and vines. On either side of the sloping ramp leading to the next level, against the terrace face, was a gallery whose roof was supported on a double row of columns; a similar gallery ran along the westward side of the court on the next level, with side chapels dedicated to Anubis and Hathor. The top terrace contained what may have been a hall of columns, with further chapels on either side and a sanctuary dug into the cliff behind. Many of the reliefs in the colonnades and chapels are of great beauty and considerable interest: one depicts the transport of two obelisks by barge from Aswan to Karnak, another the divine marriage of Queen Ahmes with the god Amon and the resultant miraculous birth of Hatshepsut herself, and a third, the maritime trading expedition sent by the queen to Punt, the land of incense beyond the Red sea.

2. The mortuary temple of Amenhotep III, which must have been the largest and most splendid of all the Theban temples. It was, however, almost completely demolished by later Pharaohs and all that is left today are a few foundations, a huge stela 30 ft. high, and the two great statues known as the Colossi of Memnon which once flanked the gateway in front of the temple pylon but now sit like lonely sentinels in the middle of cultivated fields. The statues represent Amenhotep III; with their crowns they were nearly 70 ft. high and each was hewn from a single block of stone. The northern one was the "singing Memnon" celebrated in classical times because on certain days, shortly after sunrise, it emitted a curious high note; numerous Roman tourists including the emperor Hadrian and his wife Sabina came to Thebes in order to hear this marvel, but in the reign of Septimius Severus the statue was patched with masonry and never sang again.

3. The temple of Seti I at Qurnah, which survives only in part, the forecourt and pylon having disappeared. It was dedicated in part to the funerary cult of Ramses I, the father of Seti, and was completed by Seti's son, Ramses the Great, who figures largely in the reliefs. The walls are decorated with scenes of purely religious content in which the Pharaohs make offerings to various gods or are favoured by them.

4. The Ramesseum or mortuary temple of Ramses II (Ramses the Great), which, though much ruined, retains some of its ancient grandeur. The wide outer pylon is decorated with vigorous scenes of the king's wars against the Hittites in Syria, and the inner

(TOP LEFT) A. F. KERSTING, (BOTTOM LEFT) GRAPHIC HOUSE, (ABOVE) J. ALLAN CASH

(Top left) the Colossi of Memnon, originally, with their crowns, nearly 70 ft. high, are virtually all that remains of Amenhotep III's great mortuary temple in western Thebes; (left) capitals and lintels of the massive hypostyle hall, temple of Amon-Re, Karnak; (above) the mortuary temple of Queen Hatshepsut at Dayr al Bahri, western Thebes

pylon with episodes from the battle of Kadesh and scenes from the festival of the harvest-god, Min. Tall figures of the king in the guise of Osiris decorate the pillars of the inner court. In the first court stood a seated colossus of Ramses II; only fragments of it are left, but enough to show that it was of enormous size. It must have been over 60 ft. high and weighed about 1,000 tons. The hypostyle hall beyond the second court resembles that of the temple of Karnak; beyond were further pillared halls and a sanctuary which has now disappeared. Around the temple, within the high brick enclosure wall, are very extensive remains of vaulted buildings which must have been magazines, stables, workshops and houses belonging to the temple staff. Diodorus Siculus describes the Ramesseum under the name of "the Tomb of Osymandias" (i, 47-49).

5. The temple of Ramses III at Medinet Habu. This is the latest and most southerly of the great New Kingdom mortuary temples. The general plan was modeled on that of the Ramesseum: a wide front pylon, an outer and an inner peristyle court separated by a second pylon, a large pillared hall and two smaller vestibules, and the sanctuary surrounded by smaller rooms. The hypostyle hall is partly ruined, the pillars having been dismantled to the level of the first or second drums, but the temple is otherwise well preserved. Scenes carved on the walls of the inner halls are of the usual ritual character, showing the king performing acts of worship before the gods, but in the first court there are also scenes of battle in which the king in his chariot mows down the Libyans, attacks an Amorite city, and leads Libyans, Asians and sea raiders as prisoners before Amon and Mut. On the external wall of the temple the great sea battle between Egyptians and the Peleset (Philistines), Sherden and Shekelesh and other "peoples of the sea," is depicted with much lively detail. Another outstanding relief is that on the outer face of the great pylon which shows the Pharaoh hunting wild cattle in a reedy, marshy landscape. Adjoining the temple are the remains of a palace excavated by mem-

bers of the Oriental Institute of Chicago, who have also made a complete facsimile record of the reliefs and inscriptions in the great temple. The high gate in the eastern side of the perimeter wall of the temple area is battlemented like a fortress. Within the precinct are other, smaller temples: one dates from the reign of Thutmose III and Hatshepsut, but was altered and added to in various reigns and during the Ptolemaic and Roman periods; another is the small mortuary temple of a Saite queen. There are a sacred lake and a well, and extensive remains, as in the Ramesseum, of houses and vaulted magazines built of mudbrick.

**The Palace of Amenhotep III.**—South of the temple of Medinet Habu lie the ruins of what must have been one of the finest buildings in western Thebes: the palace of King Amenhotep III and Queen Tiye at Malkata. It is in fact four palaces, one of which was occupied by the "great royal wife," for whom her husband constructed a huge lake on which she could sail in her barge. The lake, now called Birket Habu, can still be traced by a line of mounds to the southeast of Malkata. Little is left of the brick palace itself; it was excavated by G. Daressy and others, lastly by archaeologists sent out by the Metropolitan Museum of Art, New York, who were able to restore a few of the splendid wall paintings.

(M. S. Dr.)

**THEBES** (Greek THEBAI; modern Greek ΘΗΒΑΙ), a city of Boeotia, central Greece. Pop. (1961) 15,779. Thebes is situated on a low ridge dividing the two plains of Boeotia. The town has abundant springs of water, the most famous in antiquity being called Dirce, and the fertile plain in the vicinity is well irrigated. The road and railway system of east central Greece passes through Thebes, and nature makes it the chief market town of a rich agricultural area; it is the seat of the Greek Orthodox bishop of Thebes and Levadhia.

**Prehistory.**—The ancient citadel, called the Cadmea, was first inhabited in the Early Bronze Age and then taken over by a Middle Bronze Age people who probably spoke Greek and may have been called Aones (perhaps a form of Iaones; i.e., Ionians). During the 15th century B.C. a palace of Minoan plan was built on the Cadmea and adorned with frescoes showing Theban women in Minoan dress; the so-called Palace Style of pottery was in use at this time, some vases being imported from Crete, and contacts between Thebes and Knossos increased in 1450–1400 (see CRETE). Thebes became even wealthier in the period after 1400, when the rulers used golden vessels and built a great circuit wall; indeed, Boeotia rivaled Argolis as a centre of Mycenaean power until the palace and wall were destroyed about 30 years before the Trojan War, i.e., c. 1230. Greek legend attributed the citadel to Cadmus, the wall to Amphion (q.v.), and the sack of "seven-gated Thebes" to an army led by Adrastus, king of Argos (see SEVEN AGAINST THEBES); legend told, too, of Hercules born at Thebes, and of the misfortunes of Laius and Oedipus (q.v.).

The destruction of Thebes is implicit in the "catalogue" of Greek contingents in the *Iliad*, which mentions Hypothebae ("lower Thebes") and calls the leaders Boiotoi. A further invasion by Boiotoi about 1120 completed the collapse of Mycenaean civilization. Excavations begun in 1963 not only placed the final destruction of the Cadmea in the latter half of the 13th century but also threw a surprising light on the tradition that Cadmus came to Thebes from Phoenicia eight generations before Spartans en-

tered Thera (i.e., c. 1360, if the Spartans went to Thera as well as to Melos c. 1100); for a superb collection of Babylonian seals, mainly of 14th-century date, which was found in the burnt layer of the final destruction, is likely to have formed part of the crown jewels of the Cadmean royal house.

**History.**—After the migrations of the Early Iron Age the people of Boeotia were of mixed stock, some speaking an Aeolic and others a northwest Greek dialect, and at Thebes a Dorian clan, the Aegeidae, was very influential. Thebes was governed for centuries by an oligarchy of aristocratic clans that held large estates (*klaroi*), and laws were passed c. 725 to maintain the number of estates. In the 6th century a league of Boeotian cities was formed (see BOEOTIA), including Thebes. But Thebes pursued an individual policy in supporting Pisistratus, who became tyrant of Athens c. 546, and in attacking Plataea, which allied itself with Athens in 519. From this sprang a lasting enmity between Thebes and Athens, because Plataea lay just west of the main route from Thebes to the Isthmus of Corinth through the Megarid, and the alliance of Plataea and Athens threatened to cut this line of communication.

When hostilities broke out in 519, the Boeotian League supported Thebes and was defeated by Athens. In 506 Boeotia, Chalcis, and Sparta combined against Athens, but Boeotia again suffered defeat and Thebes turned to Aegina for help. When the Persians invaded Greece, 400 Thebans went to help defend Thermopylae. When they were surrounded, they surrendered, and hatred for Athens encouraged Thebes to join the Persians. The Theban cavalry and infantry fought well on the Persian side at the Battle of Plataea; the city then stood a siege of 20 days before surrendering the leaders of its close oligarchy to the Greeks (479).

A period of decline followed when Thebes was more or less under the control of Sparta or Athens and its government fluctuated between oligarchy and democracy. Then in 446 the Boeotian League won its independence. In 431 Thebes attacked Plataea and started the Peloponnesian War (q.v.), during which the Thebans won a dominant position in the Boeotian League. A number of small states sought refuge behind the city's strong fortifications; they were treated at first as equals and then as subjects. Thebes soon controlled 4 of the league's 11 wards, and the federal council met there. Moreover, Theban troops won a decisive victory at Delium (q.v.) in 424. When Athens surrendered (404), Thebes proposed its destruction, but Sparta preserved Athens as a rival to Boeotia. Thebes therefore adopted a policy of opposition to Sparta, assisting the Athenian democrats and instigating the Corinthian War (395–386). This policy failed, for Sparta disbanded the Boeotian League in 386 and placed a garrison in Thebes in 382.

For 60 years, since 446, the constitution of Thebes had been a moderate oligarchy in which the franchise was limited to the propertied class. In 379 Thebes rose against Sparta and became a democracy. As the Thebans liberated the Boeotian cities from Sparta, they reconstituted the league on a democratic basis, with an assembly of Boeotians meeting at Thebes. By reducing their neighbours to dependent status, they soon controlled three of the new league's seven wards; their leaders Melon, Pelopidas, and Epaminondas were influential in the Boeotian assembly; and their *corps d'élite*, the Sacred Band, defeated the Spartans at Tegyra (375) and Leuctra (371). In 371–362 Thebes was the leading military power in Greece. Epaminondas (q.v.) tried to make it the capital of a unified Boeotia, and Boeotia head of a group of federal states, but the people abused their position by destroying Orchomenos and placing garrisons in allied cities. In 356 Thebes used the Amphictyonic Council to lay a fine on some Phocian leaders, but these seized Delphi, hired mercenaries, and overran Boeotia. Ten years later Thebes won the war by invoking Philip II of Macedonia. But the Thebans broke their alliance with him and in 338 suffered defeat at Chaeronea (q.v.); the league was dissolved, and an oligarchic government and a Macedonian garrison were imposed on Thebes. Thebes rose twice against Alexander the Great, and in 335 his army broke through the defenses. Six thousand Thebans fell, and the city was razed except for the temples and the house of the famous Theban poet Pindar, which Alexander spared. The survivors were enslaved by order of the Greek League.

Cassander rebuilt Thebes in 316. It shared the vicissitudes of the Boeotian League, fell under the authority of Rome, and was stripped of half its territory by Sulla in 86. In Byzantine and Frankish times it prospered as an administrative and commercial centre, particularly for silk weaving; it had a large Jewish colony in the 12th century. From 1205 it was the capital of the Frankish lords (later dukes) of Athens, and a Frankish castle was built on the Cadmea. In 1311 it was taken by the Almogávares (*q.v.*). Under the Turks (1435–1829) Thebes became a village.

**THECLA, SAINT** (1st century A.D.), honoured in the East with the title "protomartyr among women and equal with the apostles," is one of the most celebrated saints in the Greek Church. The centre of her cult was Seleucia, in Isauria (south central Asia Minor), and her basilica south of Seleucia, long a popular place of pilgrimage, is mentioned in the two books of St. Basil of Seleucia. Thecla was the heroine of the apocryphal *Acts of Paul and Thecla* (late 2nd century), according to which she came under the personal teaching of the apostle Paul at Iconium. The *Acts* are of a highly fabulous character (Thecla escaped from burning, from wild beasts, bulls, and serpents) but are nonetheless interesting monuments of ancient Christian literature and probably contain a nucleus of genuine history. They were extremely popular in the early church. St. Thecla's feast day is Sept. 24 in the East, Sept. 23 in the West.

Numerous versions of the *Acts* survive. English translations include: of the Syriac, by W. Wright, in *Apocryphal Acts of the Apostles*, vol. ii, pp. 116–145 (1871); of the Ethiopic, by E. J. Goodspeed, in *American Journal of Semitic Languages and Literatures*, vol. xvii, pp. 65–95; of the Coptic, by M. R. James (ed.), in *The Apocryphal New Testament*, pp. 272–281 (1924); and of the Armenian, by F. C. Conybeare, in *The Apology and Acts of Apollonius and Other Monuments of Early Christianity*, pp. 61–88 (1894).

See L. Radermacher, *Hippolytus und Thekla* (1916); *Dictionary of Christian Biography*, vol. iv, pp. 882–896.

**THEGN** (THANE), an Anglo-Saxon word meaning "one who serves," was from early times used also of the noble members of a king's or great man's following; and their twofold duty of service in war and in peace is mirrored in the rendering of thegn as *miles* and *minister* in Latin sources. From the late 9th century it ousted the term "gesith" (companion). Over most of England men of this class had a wergild of 1,200 shillings. By the 11th century it was considered that a typical thegn would possess at least five hides of land, a church and kitchen, a bellhouse and fortified dwelling, and a seat and special office in the king's hall; but the class included men of various degrees of wealth, ranging from those with vast estates to others who economically hardly differed from the ceorl (see CHURL).

The service of the king conferred special distinction. The king's thegn is first mentioned in the laws (688–694) of Ine, king of Wessex, and (695) of Wihtried of Kent, and already he had special privileges. King's thegns from the time of Alfred (d. 899) served at court in rotation. They also played an increasingly important part in local jurisdiction and administration. In the Danelaw, a code of Aethelred II (d. 1016) shows the 12 senior thegns of each wapentake acting as a jury of presentment. The king's thegns had military duties also, and they paid a higher heriot than other thegns. By the time of Aethelred II no one but the king had jurisdiction over them. Ealdormen were normally chosen from among them.

In Scotland the title thane was applied to hereditary administrators of royal estates. It survived until the 15th century.

(D. Wk.)

**THEILER, MAX** (1899– ), South African microbiologist, who won the Nobel Prize for Physiology or Medicine in 1951 for his work on the virus of yellow fever, was born in Pretoria on Jan. 30, 1899. He received his early education in South Africa and completed his medical training at St. Thomas' Hospital, Lon-

don, and the London School of Tropical Medicine in 1922. From 1922 to 1930 he worked in the department of tropical medicine at the Harvard Medical School in Boston. There he carried out important studies on amoebic dysentery, rat-bite fever, and leptospirosis.

Shortly after the discovery by A. Stokes, J. H. Bauer, and N. P. Hudson that yellow fever was caused by a virus transmissible to monkeys, Theiler showed that the common albino mouse is also susceptible to the virus. In addition to facilitating the work on the natural history of yellow fever, his discovery led to the development of the first attenuated strain of the virus. In 1930 Theiler joined the laboratories of the Rockefeller Foundation in New York and together with E. Haagen, W. Lloyd, N. Ricci, and H. Smith carried out further fundamental studies on the yellow fever virus that led to the development of the improved (17-D) strain widely used for human immunization. He also discovered a virus disease of mice that closely resembles human poliomyelitis.

(A. B. SN.)

**THEISM** (Greek *Theos*, "God") means belief in God, but more particularly, a distinctive set of doctrines expressed in philosophical terms concerning God in relation to the world and man. While no doctrine of God is completely divorced from ideas and beliefs to be found in the historical religious traditions, theism represents a constructive philosophical position not to be identified with any particular religion. It has frequently happened that a theistic line of thought has developed within a particular religion; thus, for example, we can speak of Christian theism or of theistic interpretations of Hinduism. Theism thus appears both as a philosophico-theological position in its own right and as an identifiable strain of thought within official church theologies.

Theism is distinguished from atheism (*q.v.*), or explicit denial that there is God or a transcendent reality, and from agnosticism (*q.v.*), or the doctrine that human reason is incapable of knowledge in the theological sphere and is thus unable either to prove or disprove the existence of God. It is especially important to distinguish theism from deism (*q.v.*), a position developed chiefly by philosophers in the 18th century which emphasizes the transcendence of God over the world and conceives of God primarily as a Supreme Being or Regulator of the cosmic system. In taking God as an explanatory principle of the cosmos, deism did much to foster a contrast between the "God of philosophers" who is aloof and the "God of religion" who enters into personal relations with worshipers. Theism holds to the presence (immanence) of God in the world and human experience, although it also upholds the divine transcendence. Theism, in further contrast to deism, uses the concepts of person and self in describing the divine nature, whereas deism tends toward impersonal conceptions of the deity.

Theists distinguish their position from pantheism (*q.v.*) in some of its formulations, especially if pantheism is taken to mean the total immanence of God in the world or in man. By contrast, theism insists upon a clear distinction between God and the world; this feature serves also to distinguish theism from absolutism or religious monism in which there is an identification between God and the totality of things taken together as one fully unified and all-embracing system.

**History.**—Although the first occurrence of the term theism is to be found in the 17th century, the position is much older and can be traced back to ancient Greek philosophy. It is characteristic of theism to seek support for its contentions in rational argument and appeal to the nature of things as open to experience. Consequently, it has given rise to various types of argument for the existence of God. Rational or philosophical theology aimed at establishing the reality of God and at defining the divine nature can first be found in the philosophy of Plato, notably in Book x of the *Laws*. There Plato advanced the argument for God which combines ideas that formed the basis of the later cosmological and teleological arguments. Motion and change exist, Plato argued, but some motions are imparted to a thing from another and some belong to the intrinsic nature of the being itself. This latter or spontaneous motion belongs to souls alone; matter can have only such motion as is communicated to it from another. That motion in the universe which is communicated requires a soul

capable of communicating it. There is, therefore, a cosmic soul or God.

Aristotle is not generally described as a theist because his ultimate principle is a *nous* or intelligence rather than a soul, and his God has no personal relations with man. He nevertheless left an indelible mark upon Christian and all later theism by laying the foundations for the cosmological argument for the existence of God (*see below*). Thomas Aquinas was later to bring the cosmological argument to its classic expression in his famous "five ways" of demonstrating God's existence set forth in the *Summa Theologica*.

The ancient Stoic philosophers and the Neoplatonist tradition as represented by Proclus and Plotinus carried on the theistic tradition in ways consistent with their distinctive philosophical outlooks. (*See STOICS; NEOPLATONISM.*) With Augustine of Hippo and Anselm of Canterbury there was established the tradition of Christian Platonism and with it the ontological-type argument for the existence of God (*see below*). The cosmological and ontological arguments, together with the argument from design or teleological argument (*see below*), passed into the general philosophical tradition. These arguments were used with various transformations and reformulations by philosophers until the 18th century. Locke, Descartes, Spinoza, Leibniz, and countless others put forth their own versions of the different arguments for God and set the stage for the thorough criticism of these arguments in the 18th century, which was a turning point in the development of theism. Kant, in his criticism of reason and his doctrine that theoretical reason is limited in its application, and Hume, in his skeptical examination of the grounds of human knowledge, led to a revolution in philosophical theology. Each in his own way set forth searching criticism of the rational grounds upon which the now traditional arguments for God and the divine attributes were based. Hume, by attacking the inherent rationality of the causal principle, cast doubt upon the validity of an argument attempting to pass from the finite facts and the existence of the world to God as its Cause. Kant, by denying the validity of all purely rational or a priori arguments aimed at establishing the existence of a thing, struck at the root of the ontological argument. The further implications of his criticism become clearer when we note that he sought to show the dependence of all arguments for God on the ontological argument; if that fails, they all fail. One basic result of this criticism was the turning of attention away from more traditional patterns in theistic thought to new approaches. Kant himself pointed the way by proposing the moral approach or argument for God and by giving a new prominence to the teleological argument. It is important, however, to notice that Kant's "arguments" are of a peculiar kind and differ from previous forms. His arguments are "transcendental" and involve showing that God, as one of the transcendental Ideas, is a necessary rational condition for making morality intelligible and for enabling us to think of reality from a teleological point of view.

Despite these criticisms, theism continued to maintain itself. Considerable emphasis was placed in the 19th century upon developing the moral approach to God, and the rise and growth of the theory of Value brought forth an "axiological" argument for God as the Ground of Value both in the universe and in human experience. The development, moreover, of the theory of evolution led to a reconsideration of the idea of Providence and a closer connection between the idea of God and the interpretation of the cosmic process. The appearance of doctrines of "emergent evolution" (*see EMERGENCE*), or the idea that novel and higher forms of being appear in the course of time, played an important role in theistic thought. More recently, F. R. Tennant in his *Philosophical Theology* has argued in great detail for a "wider teleology" as the ground of an empirical theism, and Austin Farrer in his *Finite and Infinite* has revived the cosmological approach with considerable skill and with greater emphasis on man and his experience. The older cosmological arguments paid exclusive attention to the physical world.

The dominant place assumed by experience in modern thought has led to the development of the idea of religious experience.

Seeking to keep more closely in touch with actual religion, theists have identified certain types or qualities of experience, such as the "holy," the "numinous," and the sense of "unconditional obligation," as the ultimate ground of belief in God. William James in *The Varieties of Religious Experience* gave classic expression to this line of thought, and his work led to the study of the grounds of theistic belief from a psychological point of view. Present-day theists have fully accepted the idea that, without experience in some form, arguments for God are futile. Mysticism, or the intuition of God as Ultimate Unity, is often believed to represent religious experience par excellence, but theistic philosophers and theologians have appealed to this ground of belief only with the greatest caution because mystics have so frequently criticized the theistic conception of God, contending that if God is conceived merely as one being besides others he thereby becomes finite in nature.

#### Summary of the Theistic Arguments and the Idea of God.

—*Ontological Argument*.—The original and standard formulation of this argument was set forth by Anselm in his *Proslogion*. The distinguishing feature of this approach is that it starts with the idea of God and seeks to show that this idea, properly understood, implies the necessity of the divine existence. Assuming that God means "that than which nothing greater can be conceived," Anselm argued that unless the object of the concept existed beyond the concept it would not be "that than which nothing greater can be conceived" but something less. It is generally agreed that there are two arguments for God in the *Proslogion*. One takes the form of claiming that existence is a perfection among others and that since God embraces all perfections, God must exist. The other argument has to do with bare existence but with the concept of *necessary* existence. In the latter case the argument is that the reality meant by the term "God" cannot be conceived not to exist without contradiction; therefore, God exists necessarily. When it is said that the ontological argument is a priori, the meaning is that it does not set out from the existence of any finite facts but from the grasp of a meaning or a concept. It is clear, however, that Anselm regarded his formula for God as expressing the Christian conception of the deity derived from a prior tradition of thought and faith.

Later thinkers, such as Descartes and Leibniz, restated this argument so as to focus chiefly on existence. Existence, it was said, is one predicate of a thing besides others, and it constitutes a perfection. The idea of the Supreme Reality is the idea of a Reality necessarily possessing all perfections, and since one of these is existence, God necessarily exists. Though the ontological argument has been "refuted" many times, it still continues to engage the attention of philosophers and theologians. It is a witness to the ultimate relation between God and the structure of reason.

—*Cosmological Argument*.—We must be careful to distinguish between the basic principle underlying this argument and the several concrete forms it has assumed. The basic principle is that of causality or sufficient reason according to which for every existent fact there must be a cause or sufficient reason why it is so and not otherwise. The essence of the cosmological route to God is the logical transition from given fact to God as its cause. Though the starting point is fact or existence in either case, we may focus attention either on the fact of existence itself ("something exists") or upon some particular feature of what exists ("there is motion"; "there are causes"). In the first case, the argument takes the following form: since something exists, something must exist necessarily, for what exists either has the cause or reason of its existence in itself or that cause must be found in another. Therefore, since something exists, that existence is either its own cause, in which case it is necessary; or it is dependent upon another existence which has its own reason within its own nature. This existence is the necessary being or God.

In the second case, the argument takes the form of starting not with the bare fact of existence but with some particular feature of existing things such as the fact of motion or of the causal relation between things, and of arguing that, to avoid an unending chain of causes, there must be a Prime Mover or First Cause which

is the sufficient reason of the facts with which the argument began. Here the particular facet of God figuring in the conclusion of the argument is determined by the particular feature of the world from which we set out. Thus, the fact of motion leads to God as Prime Mover, the fact of purposive action leads to God as Intelligent Designer, etc.

The classic statement of the cosmological arguments was given by Thomas Aquinas in his *Summa Theologica* (Part I, Question ii, art. 3) where he set forth the "five ways" by which God's existence can be demonstrated by the light of reason. These are, in the order in which they appear in the *Summa*: the argument from motion; the argument from efficient causes; the argument from possible and necessary existence; the argument from degrees of excellence; the argument from design. The last argument has usually been described as teleological, but it is clearly of the cosmological type since, like the others, it begins with certain features of finite fact and seeks the cause or reason for those features in God. The chief idea communicated through all cosmological arguments is that the world is not self-explanatory and is dependent upon some reality beyond itself.

**Teleological Argument.**—The general form of this argument is that of starting with the observation that things in the world are so constructed as to be able to perform their functions and that in so doing they appear to be "working toward ends." The teleological proof is the inferring of a designing intelligence as the sufficient reason for such purposive activity in nature. This argument was, of course, profoundly affected by the theory of evolution in the last century, since the theory gave many instances of adaptation a "natural" explanation and seemed to require no designing intelligence or purpose. Various emphases have been dominant in the history of this argument; sometimes it has been held that the world was designed solely for the good of man and that "it is the best of all possible worlds." Other statements have focused upon the analogy between an intelligently designed mechanism such as a clock and an intelligent maker, and the universe as a system of adapted parts and a divine maker. Kant, like many others, regarded the teleological argument as the one closest to the ordinary experience and understanding of men.

**Moral Argument.**—Kant, who initiated this line of argument, held that reflection upon man as a moral being can lead us to the idea of God. Man's awareness of obligation places upon him the demand to achieve the good will; worthiness to be happy is man's proper aim. In order to understand morality as rationally consistent, we must, Kant held, invoke God as the power able to make the highest happiness and our worthiness to be happy coincide. This is not a demonstration after the manner of the other arguments but rather the idea that God is a postulate required if the moral life is to be rationally understood.

Later forms of the moral argument were more direct; they laid stress upon the idea that the authority of the moral ideal becomes insignificant unless that ideal is grounded in Reality. Moreover, it was argued, the Ideal requires embodiment in God; otherwise it has no status but that of "an ought to be" or a mere postulate. Whatever its particular form, the moral argument seeks to show that the fact of man's sense of unconditional obligation leads us on to a Ground which both supports and explains this fact.

**Theistic Conception of God.**—As regards the theistic conception of God, the dominant note has been to think of God as personal or at least as being of a nature which is not subpersonal. The main reason for this doctrine is the belief that, since experience discloses personality as the highest form of existence, the nature of God cannot be less than personal. Since, however, terms like "personal" and "person" cannot be attributed to God in the same sense in which they are used to describe finite human persons, some doctrine of analogy or symbolism has been introduced. The main aim of theists has been to hold fast to the basis upon which personal relations between God and man are possible.

Since theism insists upon a clear distinction between God and the world, it embraces a doctrine of creation according to which God is immanent in the world while preserving transcendence at the same time. The appeals made by theists to both reason and religious experience have led to analyses of the creative process

both in nature and in man as sources of insight for understanding divine creativity. Of considerable importance in theistic discussion is the question whether the world is necessary to God as God is necessary to the world. Classical Christianity has tended to hold that the world is not necessary to God, whereas theists have maintained that it is necessary. The doctrine has been advanced that some world or other is necessary to God, but that this particular world is not.

Other attributes of God, such as infinity, eternity, omniscience, and omnipotence, are treated by theists in accordance with analogies drawn from human experience. The chief problem is to understand how finite and imperfect characteristics can be understood as existing perfectly in God and also whether such perfection necessarily means a static rather than a living God.

Theists have not been unmindful of the difficulties raised for their position by the problem of evil, and various sustained attempts have been offered to show that the reality of evil is not inconsistent with the reality of God. It is important to notice that the problem of evil exists only upon the assumption that the universe is the expression of a divine ground. Consequently, the problem of evil concerns the divine nature primarily and not the prior question of God's existence. The proponents of theism have consistently developed their position against the criticism of philosophical skeptics who deny all knowledge transcending sense experience, and against theologians who deny natural theology in favour of revelation alone.

See also DEISM; PANTHEISM; and biographies of philosophers referred to above.

**THEMISTOCLES** (6th–5th century B.C.), Athenian statesman and general, more than any other single man saved Greece from the Persians. His family, the Lycomidae, was old and honourable, but his father was inconspicuous and his mother not Athenian. In an age when family alliances were powerful factors in politics, Themistocles lacked influence among the nobility and relied on the people for support.

Though little is known of his early career, the statement of Dionysius of Halicarnassus (a good scholar) that Themistocles was archon in 493/492 should be accepted. Themistocles recognized the danger threatening from Persia and began to develop the Athenian navy. Little, however, could be done before the danger became acute, and it was the hoplite infantry, under Miltiades, that won the Battle of Marathon (490). In the following years there was intense rivalry among leading politicians at Athens, reflected in a series of ostracisms, but in 483 Themistocles seized an unexpected opportunity. A new rich silver mine had been opened in the Laurium mining area, and it was proposed to distribute the windfall among the citizens. Themistocles persuaded the assembly to use the money to build a new modern fleet. Aristides, who opposed the policy, was ostracized (482), and 200 triremes were built by 480.

As Xerxes completed his preparations for invasion, Themistocles became the dominant leader in Athens. He persuaded the Athenians to accept Spartan leadership and to sink political differences by recalling the ostracized. Above all it was he who persuaded the Athenians to evacuate Attica and rely on their fleet. He was in command of the Athenian contingent in the force that won the Battle of Salamis, and when it was realized that Themistocles could not be defended he took the Athenian fleet to Artemisium; the Spartan fleet was in command, but the driving force was Themistocles. When the Thermopylae-Artemisium line had been abandoned, it was Themistocles who controlled the evacuation of

and inspired the Greek commanders to fight at Salamis. The naval victory of Salamis was the decisive turning point in the war, and Themistocles was its main architect. His new Athenian fleet formed the largest contingent, his eloquence maintained morale before the fighting, and his message sent to Xerxes that the Greeks were preparing to flee led the Persians to go into action too soon, expecting an easy victory. Themistocles was given an ovation even at Sparta. (See further GRECO-PERSIAN WARS.)

In the autumn Themistocles took the fleet through the Aegean Islands, enforcing payments toward the campaign, and he was not reticent about his achievements. His political opponents were able to profit by a swing of feeling against him, which they encouraged, and he lost his command in 479, the year in which the Persians were finally defeated by land and sea. When the leadership against Persia passed in 478 from Sparta to Athens, Themistocles was not in control. At home, however, he had outwitted the Spartans when they attempted to prevent the rebuilding of Athens' fortifications. Of Themistocles' actions and policies for the next six years very little is known. The spectacular successes of the Delian League were credited to Aristides and Cimon; Themistocles' aim seems to have been to oppose Spartan policies. He successfully resisted the Spartan attempt to get control of the Amphictyonic League by expelling medizers (states that had collaborated with the Persians), and he is said to have plotted to burn the Greek fleet that Sparta led to overthrow the medizing rulers in Thessaly (c. 476). He was *choregus* (financial backer) for the production of Phrynichus' tragedy *The Phoenician Women*, in 476, but this is the last that is heard of him in Athens. The main power rested with Aristides, Cimon, and a strong group of families associated with them, who believed that Sparta and Athens could remain in alliance. Themistocles, the sharper realist, saw that the two states were incompatible, but the people were not yet persuaded. He was ostracized (c. 473-471) and went to Argos, Sparta's traditional enemy; from this base he stirred up opposition to Sparta in the Peloponnese.

It was primarily for this reason that the Spartans implicated Themistocles in the treason of the Spartan regent Pausanias (q.v.). They were able to work on Themistocles' enemies in Athens, who brought the charge of Medism against him. Themistocles was condemned in absence. He fled from Argos, pursued by a Spartan and Athenian commission, first to Corcyra, then to the king of the Molossians, then across Macedonia to the Aegean and Ionia. When Xerxes died (465), Themistocles appealed for refuge to his son Artaxerxes and, like other Greeks before him, was honoured by the Persians. He was allowed to rule in Magnesia, and other towns were assigned for his maintenance. He probably died a natural death, though later a tradition grew up that he drank his blood to avoid the humiliation of leading Persian forces against Greece. The dates of his ostracism, condemnation at Athens (after 472), flight, arrival at the Persian court, and death are highly controversial but comparatively unimportant.

Thucydides, who is very sparing in character sketches, goes out of his way to write about Themistocles. He emphasizes his sharp intelligence and powers of analysis and anticipation. Themistocles is much more clearly than his rivals the strength and weakness of Persia. His bold decision to rely primarily on the Athenian fleet combined with the force of his personality saved Greece from the hands of his eldest daughters, Sybiris and Italia, together with his threat to sail west and occupy Siris in south Italy if the Ionians refused to stay at Salamis, suggests that he looked for the West as a base for supplies when Persia controlled the raw materials from the Black Sea and from Thrace and Macedonia. After the defeat of Xerxes he anticipated the later leaders of Athenian democracy in believing that Athens could not develop while tied to conservative Sparta. His naval policy was a decisive factor in making Athens more democratic, but this was a result rather than the intention; Themistocles was more concerned with policies than with political principles. Thucydides tells nothing of his moral qualities; other writers say too much of greed and conceit. Behind the anecdotes and rhetoric there is probably some substance. Very probably Themistocles was not

a moralists' model and was capable of sharp practice and human vanity; but he remains the greatest Athenian of his day. A Roman copy of his portrait, found in 1939 at Ostia, is probably a replica of a contemporary portrait.

**BIBLIOGRAPHY.**—Herodotus, books vii and viii; Thucydides, book i, 135-138; Plutarch, *Themistocles*; E. M. Walker in *Cambridge Ancient History*, vol. x, ch. 2 (1927). A viducentary copy of Themistocles' famous decree ordering evacuation and mobilization was discovered in 1959 at Troezen, which gave hospitality to most of the refugees. This decree, however, is inconsistent at crucial points with Herodotus' account, and its genuineness has been disputed. See M. H. Jameson in *Hesperia*, xxix, pp. 198 ff. (1960), xxxi, pp. 310 ff. (1962); A. R. Burn, *Persia and the Greeks*, pp. 364 ff. (1962); C. Hignett, *Xerxes' Invasion of Greece*, pp. 458 ff. (1963) (the last two hostile to authenticity).

(R. M.)

**THENARD, LOUIS JACQUES** (1777-1857), French chemist, author of a standard textbook on elementary chemistry, and discoverer of hydrogen peroxide, was born on May 4, 1777, at La Louptière, Aube. He worked in a humble capacity in the Paris laboratory of N. L. Vauquelin, who procured for him various teaching posts. In 1802, when Vauquelin left the Collège de France, he used his influence to secure Thenard's succession to the chair of chemistry. Later, Thenard held the chair of chemistry at the École Polytechnique and at the Sorbonne. Made a baron in 1825, he was a peer of France (1832), deputy for Yonne (1827-30), chancellor of the university, and a member of the Council of Education. Thenard died in Paris on June 21, 1857. The name of his native village was changed (1865) to Louptière-Thenard in his honour.

Thenard was a great teacher. His *Traité élémentaire de chimie théorique et pratique* (4 vol., 1813-16) did more, perhaps, than even his many important original discoveries to advance the cause of science. With his lifelong friend J. L. Gay-Lussac (q.v.) he carried out many researches. Thenard himself is especially remembered for his work on esters (1807), sebatic acid (1802), and bile (1807), his discovery of hydrogen peroxide (1818), his study of organic phosphorus compounds (1846), and his preparation of the pigment known as Thenard's blue (1799).

**THEOBALD** (c. 1090-1161), archbishop of Canterbury, members of whose household made a notable contribution to the 12th-century Renaissance, was born near Bec in Normandy. He entered the abbey of Bec, became prior (c. 1127), and was elected abbot in 1136. In 1138 he was the improbable but successful candidate for the archbishopric of Canterbury, defeating the hopes of Henry of Blois, bishop of Winchester. From 1139 to 1143 Theobald was overshadowed by Henry, who had secured the office of papal legate with powers equal or superior to those of the archbishop. Politically, as between Stephen and the Angevins (Matilda and her son, the future Henry II), Theobald was a cautious conformist, generally obedient to Stephen but showing limited support for Matilda in 1141. At Christmas 1141, however, Theobald recrowned Stephen following his release from captivity, and thereafter he recognized Stephen's title. Theobald, made legate (1150) by Eugenius III, held a council at London (1151) at which were promulgated important canons and statements of ecclesiastical liberties. The king wished his son Eustace to be crowned to secure his succession, but Eugenius forbade Theobald to carry out the rite, and the archbishop was forced to flee (1152). Soon re-instated, Theobald played a leading part in negotiating the treaty that brought Henry of Anjou to the throne, but after the crowning of Henry (1154) the rest of his episcopate was uneventful. He died on April 18, 1161. A highly competent administrator but not a great spiritual leader, his household was a notable ecclesiastical training ground, producing four archbishops and six bishops. Theobald is chiefly famous as patron of Becket, whom he made archdeacon of Canterbury, and of John of Salisbury, the historian and philosopher; and by bringing to Oxford Vacarius the Mantuan jurist he laid the foundations of the serious study of Roman law in England.

See A. Saltman, *Theobald, Archbishop of Canterbury* (1956).

(G. W. S. B.)

**THEOBALD, LEWIS** (1688-1744), English man of letters, playwright, and the first modern Shakespearean scholar, was born at Sittingbourne, Kent, son of an attorney. He was educated for

the law but soon turned to literature, publishing translations (Plato's *Phaedo*, 1713; plays of Sophocles and Aristophanes, 1714-15; etc.), bad poetry, and plays.

Theobald's importance as a Shakespearean editor, however, overshadows his unsuccessful literary career. In 1725 Alexander Pope brought out his edition of Shakespeare, and this won from Theobald a year later *Shakespeare Restored; or a Specimen of the many Errors as well Committed as Unamended by Mr. Pope in his late edition of this Poet; designed . . . to restore the true Reading of Shakespeare in all the Editions ever published*. Some of Theobald's happiest emendations are to be found in this work, but in view of the arrogant title it is perhaps understandable that it enraged Pope and caused him to make Theobald the hero of his *Dunciad*. In 1734 Theobald produced his edition of Shakespeare in seven volumes. He was the first editor to approach the text of Shakespeare with the kind of attention that was given to classical texts. He gave the readings of the early editions more authority than his own taste, and he used contemporary parallels as a guide to emendation. His emendation to the passage on Falstaff's death "and a' babbled of green fields" (Folio: "A table of green fields") was a brilliant stroke that became part of the standard text. However, Theobald's text is still based on the Fourth Folio, via the Pope he despised, and he appears to have consulted the First Folio and the quartos only when he suspected error in the text before him. Samuel Johnson said of Theobald that he was "a man of narrow comprehension and small acquisitions, with no native and intrinsic splendour of genius, with little of the artificial light of learning but zealous for minute accuracy and not negligent in pursuing it." This somewhat unjust appraisal was general, but Theobald nonetheless introduced, however intermittently, methods of the first importance in approaching Shakespeare's text. He died on Sept. 18, 1744, in London.

**BIBLIOGRAPHY.**—For a highly favourable account of Theobald's work see J. Churton Collins, "Theobald, the Porson of Shakespearean Criticism," *Quarterly Review*, vol. clxxv (1892), reprinted in *Essays and Studies* (1895). See also D. Nichol Smith, *Shakespeare in the 18th Century* (1928); R. B. McKerrow, *The Treatment of Shakespeare's Text by His Earliest Editors, 1709-1768*, British Academy lecture (1933). (M. KL.)

**THEOBROMINE:** see PURINES.

**THEOCRITUS** (c. 310-250 B.C.), Greek poet born in Syracuse, was the creator of pastoral poetry. His poems were termed idylls (*eidyllia*) by the grammarians. The word is a diminutive of *eidos* and may mean "little poems." Some, however, interpret it as meaning "forms"; i.e., the bucolic, epic or lyric forms, and apply it to Theocritus' poems because they are of many different types.

There are no sure facts as to Theocritus' life beyond those supplied by idylls xv, xvi, and xvii. One view is that after composing xvi and perhaps iv and v Theocritus left Sicily and joined the circle of Philetas in Cos, but soon found his way to Alexandria. Later, on this view, he left Egypt and went either to Cos again or to some other place; e.g., Rhodes, in the eastern Aegean. Idyll vii was almost certainly written in Cos, but probably after the visit to Egypt. The rest of the poems, except xv and xvii, which were no doubt composed in Egypt, may belong to either of the visits to Cos or to that to Alexandria.

The writings of Theocritus must be handled with caution as some of the poems commonly attributed to him have little claim to authenticity. It is possible that at an early date two collections were made, one of which included a number of doubtful poems and formed a corpus of bucolic poetry, while the other was confined to those works which were considered to be by Theocritus himself. The record of these recensions is perhaps preserved by two epigrams in the Palatine anthology, one of which (9:205) proceeds from Artemidorus, the grammarian, who lived in the time of Sulla and is thought by some to have been the first editor of the bucolic poets. He says "Bucolic muses, once were ye scattered, but now one byre, one herd is yours." The second epigram (*Anth. Pal.* 9:434) is anonymous, and is translated as follows: "The Chian is another. I, Theocritus, who wrote these songs, am one of the many Syracusans, the son of Praxagoras and famed Philinna. I never sought after a strange muse." The last line may mean he

wrote nothing but bucolic poems, or that he wrote only in Doric. The statement that he was a Syracusan is confirmed by allusions in the idylls. The *Suda Lexicon* states that besides the bucolic poems some persons also attribute to Theocritus the following: *Daughters of Proetus, Hopes, Hymns, Heroines, Dirges, Lyrics, Elegies, Iambics, Epigrams*. Except for the *Hymns, Lyrics* and *Epigrams* these works are lost.

**Authentic Poems.**—The poems which are generally held to be authentic comprise bucolics and mimes, epics, lyrics and epigrams.

**Bucolics and Mimes.**—The distinction between these is that the scenes of the former are laid in the country and those of the latter in a town. The most famous of the bucolics are i, vii, xi and vi. In i Thyrsis sings to a goatherd how Daphnis, the mythical herdsman, having defied the power of Aphrodite, dies rather than yield to a passion with which the goddess had inspired him. In xi Polyphemus is depicted as in love with the sea nymph Galatea and finding solace in song; in vi he is cured of his passion and naïvely relates how he repulses the overtures now made to him by Galatea. The monster of the *Odyssey* has been "written up to date" after the Alexandrian manner and has become a gentle simpleton. Idyll vii, the *Harvest Home*, is the most important of the bucolic poems. The scene is laid in the isle of Cos. The poet speaks in the first person and is styled Simichidas by his friends. Other poets are possibly introduced under feigned names, but the only certain identification is that of Sicelidas (line 40) as Asclepiades of Samos. Theocritus declares that he is not yet superior to the latter nor to Philetas of Cos, said to have been his teacher, but boasts that his lays have been brought by report even unto the throne of Zeus, meaning apparently that they have secured the approval of Ptolemy Philadelphus. In lines 47-48 he criticizes "the fledgelings of the Muses, who cackle against the Chian bard and find their labour lost," thus taking the side of Callimachus in his controversy with Apollonius Rhodius over the merits of epic poetry.

The other bucolic poems are less interesting. Several consist of a singing match, conducted according to the rules of amoebaeon poetry, in which the second singer takes the subject chosen by the first and contributes a variation in the same air. The peasants of Theocritus differ greatly in refinement. Those in v are low fellows who indulge in coarse abuse. This idyll and iv are laid in the neighbourhood of Crotona in southern Italy, and it seems that Theocritus was personally acquainted with Magna Graecia. Suspicion has been cast on viii and ix for various reasons. It is clear that they were in Virgil's Theocritus and that they passed the scrutiny of the editor who formed the short collection of Theocritean *Bucolics*. Nevertheless, ix at any rate is not by Theocritus.

The mimes are three in number, viz., ii, xiv, xv. In ii Simaetha, deserted by Delphis, tells the story of her love to the moon; in xiv Aeschines narrates his quarrel with his sweetheart, and is advised to go to Egypt and enlist in the army of Philadelphus; in xv Gorgo and Praxinoa go to the festival of Adonis at Alexandria. These three mimes are wonderfully natural and lifelike.

It is convenient to add to the bucolics and mimes three poems which cannot be brought into any other class: xii, a poem to a beautiful youth; xviii, the marriage song of Helen; and xxvi, the murder of Pentheus. The genuineness of the last has been attacked on account of certain crudities, but the evidence of the manuscripts and papyri is in favour of the poem. Eustathius quotes from it as the work of Theocritus.

**Epics.**—Two of these are encomia. In xvi the poet praises Hieron II of Syracuse, in xvii Ptolemy Philadelphus. Two are hymns, xxi to the Dioscuri and xxiv to Heracles; xiii is an epyllion, or short epic, the story of Hylas and the nymphs. It cannot be said that Theocritus exhibits signal merit in his epics. In xiii he shows some skill in word painting, in xvi a passage at the end, where he foretells the joys of peace after the enemy has been driven out of Sicily, has the true bucolic ring. The most that can be said of xxi and xxiv is that they are very dramatic. Three poems in this group can be dated, though only approximately. In xvii Theocritus celebrates the marriage of Ptolemy Philadelphus with his sister Arsinoë. This marriage is held to have taken place

in 277 B.C., and Arsinoë died in June 270. This poem, therefore, together with xv, which mentions (lines 23–24) the queen as alive, must fall within this period. So probably does a lost poem called *Berenice*.

The encomium of Hieron seems prior to that of Philadelphus, since in it Theocritus is a hungry poet seeking for a patron, while in the other he is well satisfied with the world. Hieron first came to the front in 276–275 B.C., when he was made "general"; Theocritus speaks of his achievements as still to come (line 73), and the silence of the poet would show that Hieron's marriage to Philistis, his victory over the Mamertines at the Longanus river and his election as "king," events which are ascribed to 270–269 B.C., had not yet taken place.

**Lyrics.**—These number four, xxviii–xxxi. The first is a very graceful poem presented together with a distaff to Theuigenis, wife of Nicias, a doctor of Miletus, on the occasion of a voyage thither undertaken by the poet. The three other lyrics are all pederastic.

**Epigrams.**—These, numbering 24, are without special merit, and their authenticity is often doubtful.

**Doubtful Poems.**—There remain the poems which are generally considered spurious. They are as follows: xix, *Love Stealing Honey*, which is anonymous in the manuscripts and has a conception of love that is not Theocritean.

Of the next group—xx, *The Herdsman*, xxi, *The Fishermen*, xxiii, *The Lover*—only xxi possesses any merit. A more interesting poem is xxv, *Heracles the Lion-Slayer*. This is a long poem consisting of three episodes, the interview of Heracles with Augeas' bailiff, the review of the king's cattle and Heracles' recital to Phyleus, the son of Augeas, of the story of the Nemean lion. The composition is not unworthy of Theocritus. *The Wooing*, xxvii, contains imitations of Theocritus, but the tone and the language betray a later writer.

**Language and Metre.**—Theocritus wrote in various dialects according to the subject. The lyrics are in Aeolic, that being the traditional dialect for such poems; xii and xxii were written in Ionic, as is stated in titles prefixed to them, but a number of Doric forms have been inserted by the scribes. The epics in general show a mixture of Homeric, Ionic and Doric forms. The bucolics, mimes and the marriage song of Helen are in Doric, with occasional forms from other dialects.

The metre used by Theocritus in the bucolics and mimes, as well as in the epics, is the dactylic hexameter. A feature in his verse which has attracted much attention is the so-called bucolic caesura. The rule is that, if there is a pause at the end of the fourth foot, this foot must be a dactyl. This pause is common in Homer, but Theocritus uses it so frequently in the bucolics that it has become a mannerism. In the epics his practice agrees with that of Homer.

Like all the Alexandrians Theocritus had no scruples about borrowing with a variation from earlier Greek writers. Homeric phrases, adapted to a new setting, crop up everywhere in his verse, but he was no slavish imitator, and despite the scholiast it seems very improbable that in ii and xv he owed any considerable debt to Sophron, the Sicilian writer of mimes. The latter idyll has resemblances to the fourth mime of Herodas, but which preceded the other it is impossible to determine.

**Theocritus' Place in Poetry.**—Like his contemporary Callimachus, Theocritus was an accomplished literary artist and modern scholarship has thrown much light on the details of his craftsmanship, but, whereas the poems of Callimachus (admittedly most survive only in fragments) must remain "caviare to the general," Theocritus makes a universal appeal to the modern reader for the reason that his bucolics and mimes, however elegantly and at times eruditely expressed, reflect human nature, which Callimachus' poetry never does. This truth needs no demonstration as regards the mimes. Cynisca and her lover (in xiv) and Gorgo and Praxinoa (in xv) are manifestly real; so too, on a higher level of art, is Simaetha (in ii), as she recounts her betrayal.

The bucolics, however, have sometimes been criticized as attributing to peasants sentiments and language beyond their capac-

ity. There is something in the criticism, but comparison with modern Greek folk songs, which owe little to literary influences, reveals many striking resemblances between them and Theocritus' bucolics and there can be little doubt that both derive from real life. That life, set in a Mediterranean scenery of flowers, sun, sea and mountainside and described by a master of style, will never lose its charm.

**THEODOLITE**, a surveying instrument used for measuring horizontal and, more often, vertical angles. It is essentially a high-precision transit consisting of an alidade with telescope, accurately graduated circles for reading horizontal and vertical angles, and the necessary level vials and reading devices. The theodolite is the basic instrument in surveying, especially in precise triangulation.

There are two general types of theodolites: direction theodolites and repeating theodolites. In the direction theodolite the graduated horizontal circle remains fixed while the telescope is pointed on several objects in turn and the direction to each is read on the horizontal circle. The value of an angle is obtained by determining differences between the observed directions. In the repeating theodolite the same angle is measured a number of times, the successive values of these measurements are accumulated on the circle, and the final reading represents the total arc described by the accumulated measurements. The desired value is then obtained by dividing the final reading by the number of repetitions. Two types of direction theodolites are in use. On the micrometer type, the circle is read by means of two micrometer-microscopes mounted diametrically opposite one another. In the optical-reading type, the circles, which are graduated on glass, are read by means of an auxiliary eyepiece mounted adjacent to the main telescope.

The phototheodolite is an instrument used in terrestrial photogrammetry and consists of a combination of a camera and theodolite mounted on the same tripod. The transit is a variety of theodolite that has a telescope mounted so that it can be completely reversed or transited. A special low-precision theodolite that measures the angular horizontal drift and angle of elevation of pilot balloons is used in meteorological observations of wind direction. (K. S. Cs.)

**THEODORA** (c. 500–548), wife of the Byzantine emperor Justinian I (q.v.), was born presumably in Constantinople. According to Procopius, the chief but by no means entirely reliable authority for her life, she was the daughter of Acacius, a bear-keeper in the circus at Constantinople, and while still a child appeared on the stage.

Becoming a noted courtesan, she accompanied a certain Hecebolus to Pentapolis (in north Africa), of which he had been appointed governor. Having quarreled with him, she returned first to Alexandria and then went back to Constantinople through the cities of Asia Minor. In Constantinople she attracted the notice of Justinian. He desired to marry her and eventually achieved this by getting his uncle, the emperor Justin I, to repeal the law forbidding the marriage of senators with actresses (523). On Justin's death Justinian and Theodora became sole rulers of the Roman world (527). He was then about 44 years of age, and she about 20 years younger.

Theodora speedily acquired great influence over her husband. At a time of acute crisis when the Nika insurrection broke out in

532, her courage and firmness in refusing to fly when the rebels were attacking the palace was a contributing factor in saving her husband's crown. In the religious controversy which divided the empire, Theodora sided with the Monophysites and strongly supported the heretics of Egypt and Syria. After her marriage she lived a strictly moral life, and as empress she instituted homes for prostitutes. She was delicate in health and died early, perhaps of cancer, on June 29, 548. In appearance she was small in stature and rather pale, but with a graceful figure, beautiful features and a piercing glance. In the apse of the church of San Vitale at Ravenna there is a striking contemporary mosaic portrait of her. Whatever her early life there can be no doubt about her beauty, intellectual gifts and imperious will. (J. M. Hv.)

MANSELL-ALINARI

THEODORA AND ATTENDANTS: FROM A MOSAIC IN THE CHURCH OF SAN VITALE, RAVENNA

**THEODORE, SAINT** (602–690), archbishop of Canterbury from 668 to 690, the first archbishop to rule the whole English church, was appointed by the pope after the English candidate, Wigheard, had died in Rome, and Hadrian, the African abbot of a monastery near Naples, had refused the preferment. The choice of Theodore, a Greek from Tarsus, already 66 years old, seems extraordinary but proved successful. He was consecrated on March 26, 668, and set out from Rome on May 27, with Abbot Hadrian, who was sent to ensure that he instituted no Greek practices, and the Anglo-Saxon Benedict Biscop, later the founder of Monkwearmouth and Jarrow. After various delays, during which Theodore spent some time with Agilberht, bishop of Paris, who had been bishop in Wessex and could inform him of conditions in the English church, he reached Canterbury on May 27, 669. He made Hadrian abbot of the monastery of St. Peter and St. Paul, Canterbury, and between them they created a famous school, which drew pupils from all over the country and from Ireland, including the distinguished scholar Aldhelm. It taught Greek as well as Latin, the interpretation of the Scriptures, church music, computation, and some medicine. Through Benedict Biscop, its influence reached Bede.

Theodore brought order into the English church. Many sees were vacant on his arrival; others needed to be divided. He made a visitation of his province, filled the vacancies at Dunwich, Rochester, and Winchester, and put Wilfrid at York, removing Chad, whom later he made bishop of Lichfield. To divide dioceses was more difficult. When, in 672, he called at Hertford the first general synod of the English church, the division had to be postponed. Later he divided the East Anglian see into Dunwich and Elmham, and Northumbria into York, Lindisfarne, and Hexham; and established sees at Worcester and Hereford and for Lindsey. At times there was a separate see for the Middle Angles, at Leicester.

He eradicated Celtic usages. The synod of Hertford imposed the Roman Easter and laid down that bishops should not interfere in other dioceses, and clerics and monks should not wander without the permission of their superiors. It established an annual synod at Clofesho (a place not yet identified), and it reaffirmed the church teaching on marriage and divorce. A synod at Hatfield on Sept. 17, 679, was held to affirm the freedom of the English church from the Monothelite heresy. His *Penitential*, a collection of his rulings made by his disciples, shows that he had to deal with heathen practices as well as various moral offenses and reveals his wisdom and humanity in allowing remarriage after five years to those separated by captivity or other hopeless circumstances. This penitential was to become very influential on the continent as well as in England. It is probable that he introduced the use

of written documents to confirm grants of land to the church.

Theodore lived to be 88, dying on Sept. 19, 690. In his later years he was present at the Council of Twyford in Northumbria, which elected Cuthbert as bishop, and he consecrated him in 685. In 686 his quarrel with Wilfrid, begun when he divided the diocese of Northumbria, was composed. No biography of him has survived, and too little is known of this remarkable man. The strength of his influence is shown by his securing a settlement after the Battle of the Trent (678, between Egrifh of Northumbria and Aethelred of Mercia) without any vengeance being taken for the Northumbrian prince slain in it. His dealings with Wilfrid and his deposition of Chad from York and of Winfrith from Lichfield show that he could take firm action, but the great success of his reorganization implies a power to secure the cooperation of others.

**THEODORE, SAINT**, STUDITES (759–826), Byzantine abbot and leading opponent of iconoclasm (see **ICONOCLASTIC CONTROVERSY**), was born in Constantinople, where he received a careful education with a view to entering the imperial civil service. But, under the influence of his uncle Plato, he became a monk and later joint abbot of the monastery of Saccudion in Bithynia. His first involvement in politics resulted from his opposition to the adulterous second marriage of the emperor Constantine VI (795); Theodore was exiled to Thessalonica, but after the emperor's overthrow in 797 he was recalled by the empress Irene. Thereafter the whole community of Saccudion was transferred to the monastery of Studius in Constantinople, of which Plato and Theodore became abbots. In 806 Theodore entered into conflict with the patriarch Nicephorus, was condemned by a council, and exiled a second time (809–811). When iconoclasm was revived by Leo V, Theodore became the leader of the opposition and was once more exiled (816–820). Recalled by Michael II, whose sympathies lay nevertheless with the iconoclastic party, Theodore was not allowed to resume the direction of the Studius monastery. With his monks, he spent the remainder of his life in the vicinity of the capital. He died on the island of Prinkipo (modern Buyuk, of the Princes' Islands, in the Sea of Marmara) in 826 on Nov. 11, which is kept as his feast day.

Theodore's writings include homilies, catecheses addressed to the Studite monks, three polemical treatises against the iconoclasts, and nearly 600 letters (a valuable historical source). Theodore's activity was mainly dedicated to the independence of the church from interference on the part of imperial power; since the patriarchs of Constantinople were often obliged to compromise with the emperors, Theodore did not hesitate to oppose the patriarchs as well and appeal over their heads to the pope of Rome, thus establishing a principle of insubordination that was to prove dangerous to the Byzantine church.

**BIBLIOGRAPHY.**—Most of Theodore's works are in J. P. Migne, *Patrologia Graeca*, vol. 99 (1960). See also Alice Gardner, *Theodore of Studium* (1905); J. B. Bury, *A History of the Eastern Roman Empire* (1912); P. J. Alexander, *The Patriarch Nicephorus of Constantinople* (1958); H. G. Beck, *Kirche und theologische Literatur im Byzantinischen Reich* (1959). (C. A. Mo.)

**THEODORE**, the name of two popes.

**THEODORE I**, pope from November 642 to May 649, was a Greek, born in Jerusalem. Noted for his generosity to the poor, he had to devote most of his attention to the struggle against Monothelitism (see **MONOTHELITES**).

Theodore I refused to recognize the uncanonically installed patriarch of Constantinople, Paul. In 648 he excommunicated Paul's predecessor, Pyrrhus, who had relapsed into Monothelitism, and the next year he declared Paul's deposition for the same heresy.

**THEODORE II**, pope for 20 days in December 897, recognized the validity of the acts of the deceased Pope Formosus (*q.v.*), whose outraged corpse he reburied. (A. G. Br.)

**THEODORE** (THEODORE LASCARIS), the name of two Byzantine emperors at Nicaea.

**THEODORE I** (c. 1175–1222), a son-in-law of the emperor Alexius

III by whom he was granted the title of despot, distinguished himself during the sieges of Constantinople by the Latins during the Fourth Crusade (1203-04), and after the capture of the city gathered a band of refugees in Bithynia, first at Brusa and then at Nicaea. While the crusaders fought the Bulgarians in Thrace, Theodore formed a new Byzantine state in Asia Minor and in 1208 assumed the title of emperor. He defended his infant empire not only against the crusaders but also against David Comnenus, a rival Greek emperor in Trebizond, and against the Seljuk Turks, who had come to terms with the Latin emperor Henry and given asylum to the fugitive emperor Alexius III. Theodore, however, defeated and killed the sultan Kaikhosrau in battle at Antioch on the Maeander (1211) and captured Alexius III; and in 1214, after several months of warfare, he made a treaty with Henry defining the frontiers between the Greek empire of Nicaea and the Latin empire of Constantinople and annexed much of the territory of Trebizond. After Henry's death (1216) he further strengthened his position with regard to the Latins by taking as his third wife Maria, daughter of the empress Yolande, and by willingness to discuss union between the Greek and Latin churches. In August 1219 he made a lucrative commercial agreement with the Venetians in Constantinople; and in 1222 he negotiated a settlement with Yolande's son and successor, Robert of Courtenay, to whom he betrothed his daughter Eudocia. He died in the same year, having transformed Nicaea from the centre of a mere resistance movement against the crusaders into the capital of the Byzantine Empire in exile, recognized as the legitimate successor of the empire in Constantinople.

THEODORE II (1222-1258), the grandson of Theodore I and son of John III Vatatzes (q.v.), whom he succeeded in November 1254, was an able ruler, a good soldier, and a man of letters, although his health and character were increasingly affected by severe attacks of epilepsy. He successfully held together the prosperous state bequeathed to him by his father, but his somewhat autocratic policy brought him into conflict with many of his nobles and military commanders. He led two victorious campaigns against the Bulgarians (1255-56), who had broken the bounds set to their dominions in Thrace by John III; but his attempt to take advantage of his Greek rival, the despot of Epirus, by marrying his daughter to the despot's son provoked serious warfare in Macedonia. He died in August 1258, having aggravated the mistrust of the army and the aristocracy by appointing a commoner, George Muzalon, as regent for his infant son, John IV.

(D. M. N.)

THEODORE OF MOPSUESTIA (c. 350-428/429), an eminent early Christian theologian, was born at Antioch (in modern Turkey). Together with his friend St. John Chrysostom he studied rhetoric under the celebrated pagan sophist Libanius, with the intention of becoming a lawyer. But in 369 under the influence of Chrysostom he turned to ascetic life, entered the school of Diodore of Tarsus in a monastery near Antioch, and spent some time as a monk. Two letters written to him by Chrysostom show that his decision had caused him trouble and that he contemplated turning back; but the advice of his respected friend became decisive for his future.

The chronology of Theodore's life can be established only very generally. There is evidence that he was still alive in 428, but his death must have occurred soon after this. He must have become bishop of Mopsuestia in Cilicia (the modern Misis near Adana in southern Turkey) about 392, since Theodoret (*Historia ecclesiastica*) says his episcopate lasted 36 years.

Theodore was an important figure among the patristic authorities. Not only was he active in all the theological controversies in the contemporary Greek-oriental church but he also was an author of note. He is reported to have started his exegetical works in 402/403, and it is known that he had written some works earlier, including 15 books on the incarnation. But all these were merely a prelude to a literary outburst that astounded his contemporaries. Those of Theodore's works that have survived in their original

Greek are only remnants which do not give an idea of the scope of his writing. The Nestorian scholar 'Abdisho made a list of them which gives the titles of 41 volumes. It indicates that Theodore wrote commentaries on almost all the biblical books as well as works on theological and practical problems such as the incarnation, the sacraments, the Holy Spirit, priesthood, exegetical method, theological controversies and monasticism.

An important event in the transmission of Theodore's works was their translation into Syriac in the school of Edessa under the directorship of Qiyore (d. c. 437). Before that, the works of Ephraem Syrus had been used for instruction; afterward those of Theodore became normative. Even more important to modern historians, because of this translation a number of Theodore's lost works have been salvaged in Syriac. His commentary on the Fourth Gospel has long been known, but later discoveries have brought to light a disputation held in Anazarbus and commentaries on the Lord's Prayer, the Nicene Creed and the sacraments. His work on the incarnation was discovered in a codex in Seert, Turkey, but unfortunately the collection of manuscripts was destroyed in World War I.

The man who speaks through these works compels admiration. He is a scholar of astounding knowledge. In thoroughness and consistency of thought he is surpassed by none among his contemporaries and predecessors. As an independent inquirer he approached problems with critical standards unheard of in the ancient church. Instead of allegorical interpretation Theodore used scientific, critical, philological and historical methods, anticipating much in modern scholarship. In literary critical analysis he took into account the historical circumstances in which the biblical books were written; thus in regard to the Psalms he anticipated the modern view that many of them belong to the 2nd century B.C., and as a result of these criteria he rejected as uncanonical a number of books, including Chronicles, Esdras and the Catholic Epistles.

In his theology he insisted on the separation of the two natures, divine and human, in the person of Christ, based on his psychological analysis of personality. Since only elements of the same substance can become one, and since the human nature must find its expression hypostatically, Theodore could not conceive of a complete union between the two natures. The only way feasible was the union in terms of some kind of *synapheia* or voluntary and moral union, comparable to that between man and wife or body and soul. At the heart of his Christological definition lies the biblical thought-world with its concrete imagery. As such Theodore's Christology has provided a balance against the wave of ontological conceptions of the Alexandrians, drawn from philosophical abstractions. Through his appreciation of the human nature in Christ, and his keen interest in the biblical evidence, Theodore saved Christendom from falling into pure and shoreless speculation. His merit is that at least in principle the human nature in Christ was secured at the Council of Chalcedon (451).

As the greatest exegete and the spiritual head of the Antiochian school, Theodore became the leader for a number of outstanding spirits of the 4th and 5th centuries. The Nestorian church regards him as "the holy friend of God" and "the Interpreter" (see NESTORIANS). The Monophysite and Orthodox churches saw in him the arch-heretic. However, Theodore died at peace with the church; only once is it recorded that opposition rose against his views, expressed at Antioch in a sermon against the use of the term *Theotokos*, "God-bearer," as a title of the Virgin Mary (see MARY). The wave of controversy rose to its height soon after his death and was eagerly supported by the Alexandrians. Theodore's views and writings were condemned at the council of Constantinople (553; see COUNCIL).

**THEODORET** (c. 386–c. 466, or c. 393–c. 458), bishop of Cyrrhus (in Syria), an important Christian writer in the areas of exegesis, dogmatic theology, church history, and ascetic theology. His chief importance is as a dogmatic theologian—as the most considerable opponent of the Christological views of Cyril and Dioscorus of Alexandria and the friend, though not entirely supporter, of Nestorius. Theodoret was born in Antioch. At an early age he entered the cloister, and in 423 he became bishop of Cyrrhus, a small city in a wild district between Antioch and the Euphrates. There, except for a short period of exile, he spent the remainder of his life.

As an exegete Theodoret belongs to the Antiochene school, of which Diodore of Tarsus and Theodore of Mopsuestia were the heads. He was not actually the personal disciple of either, but he adopted their literal-historical methods, though without the consistency and boldness of Diodore. His extant commentaries (on the Song of Solomon, on the Prophets, on the Book of Psalms and on the Pauline Epistles) are brief.

For more than 20 years Theodoret maintained the struggle against the Alexandrian dogmatic and its formulas and taught that in the person of Christ we must strictly distinguish two natures (*hypostases*), which are united indeed in one person (*prosopon*) but are not amalgamated in essence. For these years his history coincides with that of the Eastern Church from 430 to 451, and for this reason it is impossible to sketch it even briefly here. The issue, not unfavourable to Theodoret's cause, was melancholy enough for Theodoret himself: the Council of Chalcedon (451) condemned Monophysitism, but Theodoret was obliged to take part in pronouncing "anathema upon Nestorius, and upon all who call not the Holy Virgin God-bearer [*Theotokos*], and who divide the one Son into two." (For details about this important theological controversy, see *JESUS CHRIST: The Dogma of Christ in The Ancient Councils*; CYRIL, SAINT; NESTORIUS.)

Some of Theodoret's dogmatic works are no longer extant. Of his five books *On the Incarnation*, for example, directed against Cyril after the Council of Ephesus, only fragments remain. A good deal of what passes under his name has been wrongly attributed to him. Certainly genuine are the refutation of Cyril's 12 anathematisms of Nestorius (later a subject of the Three Chapters controversy and condemned by the second Council of Constantinople in 553); and *The Mendicant (Eranistes)*, or *Polymorphus* (written about 446), consisting of three dialogues, entitled, respectively, "Immutability," "Inconfusibility," and "Apathy," in which the Monophysitism of Cyril is opposed and its Apollinarian character insisted on. Among the apologetico-dogmatic works of Theodoret must be reckoned his ten discourses *On Providence*.

The 30 ascetic biographies of his *Religious History*, which has been widely read, form a pendant to the *Historia Lausiaca* of Palladius; for the East it has had the same importance as the similar writings of Jerome, Sulpicius Severus, and John Cassian for the West. His *Church History* carries the work of Eusebius down to 428. Theodoret's *Therapeutike* is one of the finest Christian apologetic works; and 232 of his letters have survived.

Theodoret's collected works were edited by J. Sirmond, 4 vol. (1642), and afterward completed by J. Garnier (1648). A reprint of this with additions, by J. L. Schulze and J. A. Nösselt, may be found in J. P. Migne, *Patrologia Graeca*, vol. lxxx–lxxiv. The *Church History* was edited by L. Parmentier (2nd ed., 1954). The *Correspondance* (vol. i, 1955) and *Thérapeutique* (1958) were edited with French translations in the "Sources Chrétiennes" series.

**THEODORIC THE GREAT**, Ostrogothic king of Italy from 493 to 526, was born c. 454–455, the son of Theodemir and Ereliva. About the time of Theodoric's birth the Ostrogoths were liv-

ing under the rule of Theodemir and his two brothers in northern Pannonia as federates of the Romans. As a result of a dispute between them and the Eastern Roman government in 461, Theodoric was sent as a hostage to Constantinople, where he received a Roman upbringing, though it is said that he never learned to write. In 469 he was allowed to return to his people, among whom he quickly won fame as a warrior. Theodemir died c. 471, and in that year Theodoric was elected as his successor. Before 475 he had led his people down the Danube from Pannonia to Lower Moesia. A number of Ostrogoths in Roman service at this time were led by one Theodoric Strabo; and in the war between Basiliscus and Zeno (q.v.) Strabo supported the former, while Theodoric upheld Zeno. When Zeno recovered his throne, he gave Theodoric the post of master of soldiers, which Strabo had hitherto held; he also appointed him patrician and even adopted him as a son. In the years following 477 great confusion was caused in the Balkan provinces by the rivalry of the two groups of Ostrogoths and by Zeno's attempts to play off one against the other. Much devastation was caused by the marches and countermarches of the various armies, and several cities were sacked. But in 481 Strabo died as a result of a fall from his horse; and in 483 Theodoric and his people were settled by the Romans in parts of Moesia and Dacia Ripensis. In 484 Theodoric was appointed consul; but hostilities between him and the empire broke out again in 486, and in 487 he almost captured Constantinople itself. Zeno finally rid himself of the troublesome Ostrogoths by appointing Theodoric to supersede Odoacer (q.v.) in Italy. Theodoric set out from Moesia in 488 and arrived in Italy in 489. On Aug. 28 he defeated Odoacer on the Sontius (Isonzo) River and a month later defeated him again near Verona. Odoacer fled to Ravenna but was able to face Theodoric once more in the following year. On Aug. 11, 490, Odoacer was utterly defeated on the Addua (Adda) River and again fled to Ravenna. All the rest of Italy and Sicily now came over to Theodoric, but Ravenna held out against him for 2½ years. It was only on March 5, 493, that Theodoric was able to enter the city after an agreement that the two antagonists should rule Italy jointly. But Theodoric treacherously killed Odoacer with his own hand on March 15 and also had Odoacer's surviving soldiers massacred.

In 497 his position in Italy was defined and recognized by the East Roman government. Italy was to remain part of the Roman Empire. Theodoric still held his post of master of soldiers, which had been confirmed in 483, and, although he was in many ways an independent ruler, he was to recognize the overlordship of the emperor at Constantinople. Thus, although Theodoric could modify existing Roman laws, he could not originate any new legal principle. He was allowed to nominate one consul each year, but he was not allowed to appoint a Goth to this post. The Roman civil administration was retained in Italy, but all Goths were excluded from holding office in it and from sitting in the Roman Senate. On the other hand, the army was exclusively Gothic, and no Roman was liable to military service. Inter-marriage between Roman and barbarian had been forbidden on pain of death by Valentinian I (q.v.); and this law still remained in force. But there was one matter in which the Romans of Italy felt themselves to be wronged: all lawsuits between Romans and Goths were to be heard by Gothic military courts.

Theodoric and his people differed from the Romans in religion, for they were Arian Christians. But Theodoric's religious policy was one of consistent toleration, and he made no effort to fuse the Goths and the Romans in religion or in anything else. His impartiality was such that when two rival popes were appointed in Rome in 498 (see SYMMACHUS, SAINT), the Catholics there actually appealed to him to decide between the two claimants. It is true that there were periods of tension between the Goths and Constantinople, but these were few and unimportant. With the barbarians of the West he remained on friendly terms, and this friendship was confirmed by a series of matrimonial alliances with the various royal houses of the Visigoths, Burgundians, Franks, etc. But he could not save the Visigothic kingdom in Gaul from being overthrown by the Franks in 507, though he saved Narbonne for the Visigoths and annexed Provence for himself.

Theodoric made Ravenna his capital, and there his church, dedicated to St. Martin, still stands, known now as S. Apollinare Nuovo. There still exists, too, the round mausoleum that he built for himself. The peace and prosperity that Italy enjoyed under his rule are highly praised by writers of the time. But the closing years of the reign were clouded by strained relations with Constantinople and with the Vandals of Africa, by tension between the Goths and the Italians, and by the execution of Boëthius (*q.v.*) and other senators on a charge of treason in 524. Theodoric himself died on Aug. 30, 526, having first recommended to the Goths that his grandson Athalaric should succeed him. For events in Italy after his death, see *AMALASUNTHA*; for the German legend, see *DIETRICH VON BERN*. See also references under "Theodoric" in the Index.

**THEODOSIUS**, the name of two Roman emperors and a Byzantine emperor.

**THEODOSIUS I the Great** (347-395), Roman emperor 379-395, was a Spaniard, born at Cauca in Gallaecia, the son of a family of large landowners. His father, also called Theodosius, had served with great distinction under Valentinian I, reconquering Britain in 367-369 from the Saxons, Picts, and Scots, expelling the Sarmatians from Moesia in 371, and crushing the revolt of Firmus in Africa in 375. For unknown reasons, however, the elder Theodosius was put to death at Carthage in 375-376 either by Valentinian or by his son Gratian. The younger Theodosius had distinguished himself in a campaign against the Sarmatians in 374, but on his father's death he retired to his estates in Spain, where he married Aelia Flaccilla *c.* 376. But in 379, after the great defeat and death of Valens (*q.v.*) at the hands of the Visigoths at Adrianople, Theodosius was recalled by Gratian and on Jan. 19 was proclaimed emperor by him at Sirmium. It is not known who suggested the name of Theodosius to Gratian.

Gratian himself undertook the government of the West, leaving Theodosius to deal with the East. His first task was to restore order to the Danubian provinces that had been overrun by the Visigoths following the disaster at Adrianople. He tightened up the army laws so as to bring in more recruits, but despite some minor military victories the Balkan provinces were severely ravaged by the barbarians; it was not until Oct. 3, 382, that he was able to sign a peace treaty with the Visigoths. By the terms of this treaty the Goths were allowed to settle between the Danube and the Balkan mountains, living under their own laws and rulers and united with the Romans only by a military alliance, though they recognized the overlordship of the emperor. This seems to have been the first more or less independent Germanic state to be set up inside the frontiers of the Roman Empire, and the arrangement worked fairly well for the rest of Theodosius' life.

The emperor was much occupied early in his reign with religious matters. He was the first Roman emperor to dispense with the old pagan title of *pontifex maximus*, and he appears immediately to have determined to establish Catholicism as the state religion of the empire. A law issued on Feb. 28, 380, ordered all the peoples of his realm to subscribe to the dogmas of Nicaea.

Arians, Manichaeans, and pagans were assailed in turn. Both legislation and the three Councils of Constantinople were used to establish the power of Catholicism and to define its doctrines (see *COUNCIL*). These measures finally smashed Arianism.

After the suppression of the revolt of Magnus Maximus (see *MAXIMUS*), Theodosius visited Rome in 389. In 390 he had about 3,000 persons massacred at Thessalonica as punishment for a riot; as a result, when he visited Milan, St. Ambrose refused to meet him until he did public penance for his cruelty. In 391 he renewed his attacks on paganism. When Valentinian II died suddenly at Vienne on May 15, 392, a rebellion broke out in Gaul headed by a pagan Frank named Arbogast, who had been Valentinian's leading general. On Aug. 22 Arbogast proclaimed as emperor a Roman professor of rhetoric called Eugenius. The revolt had a decidedly pagan character, although Eugenius personally was a Christian. At first he tried to reach an accommodation with Theodosius, and, while the negotiations were still going on, Arbogast inflicted a severe defeat on the Franks beyond the Rhine in order to secure his rear. Theodosius refused to recognize Eugenius, and the latter occupied Italy in 393; Spain was also in his hands.

In 394 war broke out between the emperor and the usurper. Theodosius aimed at marching to Aquileia, and Arbogast decided to engage him in the valley of the Frigidus (Vipacco) River, a tributary of the Isonzo. On Sept. 5 Theodosius' Gothic troops were repulsed with heavy losses, but the battle was resumed the following day and resulted in a complete victory for the emperor. Eugenius was beheaded, and Arbogast committed suicide. Theodosius then visited Rome once again; but on Jan. 17, 395, he died at Milan. He was succeeded by his sons Arcadius and Honorius (*qq.v.*).

**THEODOSIUS II** (401-450), Eastern Roman emperor 408-450, was born at Constantinople on April 10, 401, the son of Arcadius (*q.v.*) and Eudoxia. He was crowned Augustus on Jan. 10, 402, and became sole ruler of the East when his father died on May 1, 408. His first regent was the able administrator Anthemius, praetorian prefect of the East. On July 4, 414, Theodosius' sister Pulcheria (*q.v.*) was created *Augusta* and soon became her brother's regent; it is not known what became of Anthemius. Pulcheria paid particular attention to her brother's upbringing, and her court was one of great piety. Theodosius, who was of a studious character, was deeply interested in theology and grew into a man of kind and gentle ways.

The chief political problems he had to face were the occupation of Africa by the Vandals in 429 and the accession to power of Attila (*q.v.*) beyond the Danube in 434. The East Roman campaigns against Africa in 431 and 441 were failures, and Theodosius' policy of appeasing Attila did not prevent the great Hun invasions of the Danubian provinces in 441-443 and 447. The reign was also troubled by the heresy of Nestorius (*q.v.*), whom Theodosius appointed patriarch of Constantinople in 428 and who was deposed as a result of the Council of Ephesus in 431. Other important events of the reign were the refortification of Constantinople in 447, the foundation of the University of Constantinople in 425, and the publication of the Theodosian law code in 438 (see *ROMAN LAW*). Nine years were spent in compiling the code, which is a collection of laws issued by the emperors from the time of Constantine the Great to that of Theodosius himself. Theodosius died on July 28, 450, after a hunting accident. He married Eudocia on June 7, 421, and had two daughters, Eudoxia (who married the Western emperor Valentinian III) and Flaccilla, and a son named Arcadius, who died in infancy. (E. A. T.)

**THEODOSIUS III** (d. after 717), Byzantine emperor from 715 to 717, was an obscure tax collector of southwestern Asia Minor who against his will was proclaimed emperor by the troops of the Opsikion theme rebelling against Anastasius II. His supporters successfully captured Constantinople after a six months' siege, and Anastasius was deposed and entered a monastery. Theodosius was quite unsuited to imperial office and in 717 was forced to abdicate by the able commander of the Anatolikon troops Leo III (*q.v.*) the North Syrian and ended his life in a monastery at Ephesus. (J. M. Hv.)

**THEODOTIOT** (fl. 2nd century A.D.), the author of a Greek translation of the Old Testament extant only in parts. Nothing is known of his life; according to Irenaeus (late 2nd century) and Eusebius (4th century), he was a Jewish proselyte of Ephesus. Theodotiot's version, which appeared in the sixth column of Origen's Hexapla, is not so much an independent translation as a revision of the Septuagint (*q.v.*), supplying its omissions. Theodotiot's version shows acquaintance with Aquila's version (see *AQUILA*). Peculiar Hebrew words are not translated but transliterated into Greek letters, either in order to avoid conjectural readings or to give an authentic colour to the version. Its popularity in the early church can be deduced from its fragments that fill gaps in the Septuagint text of Jeremiah and from its version of Daniel that replaces the Septuagint translation, as well as from its quotations in the New Testament, the *Shepherd of Hermas*, and Justin Martyr. The replacement of Daniel was so thorough that only two manuscripts (Chester Beatty Papyrus IX, of about the 3rd century; and the Codex Chisianus, of the 11th century) of the Greek Old Testament contain the Septuagint version. Theodotiot's version of Daniel may go back to an older translation.

(P. A. H. DE B.)

**THEODULF** (*THEODULFUS*, *THEUDULFUS*) (c. 750–c. 821), bishop of Orléans, poet, abbot of Fleury and Saint-Aignan, and one of the leading theologians of the Frankish Empire, was born in mid-8th century, probably in Spain, though some authorities suggest Lombard or Ostrogothic origins. Brought to Charlemagne's court by the emperor, Theodulf became bishop of Orléans in 775 and abbot of Fleury in 781. In 800 he was with Charlemagne in Rome, and in 802 he was involved in dispute with the monastery of St. Martin of Tours and with Alcuin, after whose death he became Charlemagne's chief theological adviser. In 809, before the Council of Aix-la-Chapelle, the emperor consulted him on the procession of the Holy Spirit, and in 811 Charlemagne commanded him to write a treatise on baptism ceremonies, which survives. Theodulf received the pallium from Pope Stephen IV in 816. In 818, after Charlemagne's death, his son Louis I the Pious deposed Theodulf, imprisoning him in a monastery in Angers, for supposed participation in the conspiracy of Bernard of Italy. Theodulf died either in prison or shortly after the amnesty of 821. Legend relates that Louis, riding through Angers, heard Theodulf singing his Palm Sunday sequence through the bars and pardoned him.

Theodulf's poem *Ad Carolum Regem* gives a lively but romanticized picture of Charlemagne surrounded by children, grandchildren, and courtiers. Theodulf, a reformer, established a *hospitium* for travelers and the poor; he was also a patron of the arts and a builder and restorer of churches.

Theodulf's works, edited by J. Sirmond (1646), are reprinted in J. P. Migne, *Patrologia Latina*, vol. cv, 191-390 (1851); see also C. Cuissard, *Théodulpe évêque d'Orléans* (1892). (A. Fe.)

**THEOGNIS**, Greek elegiac poet, active at Megara in the late 6th and early 5th century B.C. (the tragedian Theognis, mocked by Aristophanes in *Acharnians*, line 11, was a different person). Plato calls the elegiac poet Theognis a citizen of Sicilian Megara (*Laws*, I, 630 A); allusions in his poems make it more likely that he came from Megara in mainland Greece (as some ancient authorities also say). He is said to have written a poem on an unidentifiable episode in the history of Syracuse, and 2,800 lines of admonitory verse, together with (or perhaps including) a collection of maxims, to his beloved, Cynurus. Fewer than 1,400 lines survive, very unequally divided into two books, each containing a number of short poems in elegiac couplets, many of which are addressed to Cynurus, son of Polypaüs. Most of the poems in the first book are on admonitory themes, being especially concerned with the advantages and disadvantages of good breeding (both physical and social) in a sadly degenerate world; these are treated sometimes in satirical and sometimes in convivial terms.

The poems in Book II—and some of those in Book I—are erotic, with a marked leaning toward pederasty.

The poems ascribed to Theognis provide more than half the surviving evidence for Greek elegiac poetry of the classical period, they are important also for the picture they give of an aristocratic society in a changing world. They have therefore been much studied, and not least because they were very vulnerable to 19th-century "critical" scholarship: the divisions between the poems are clearly marked, and some passages closely resemble passages attributed elsewhere to other authors. Hence it has been found possible to deny the Theognidean authorship of nearly every piece in the collection; some poems are condemned as plagiarisms, and others because they are thought to be inconsistent in style or argument with those poems that the critic is willing to accept as genuinely Theognidean. Theognis feared both plagiarism and interpolation; a "seal" is to be set upon his verses, to mark the genuine ones (lines 19 ff.)—but the nature of that seal is disputed, and the "Theognidean question" is still open.

## THEOLOGICAL EDUCATION, CHRISTIAN.

The Christian church has always been a teaching church, for it began with the life and work of a teacher. Christian theological education, therefore, owes its origins to his remembered command: "You shall love the Lord your God . . . with all your mind."

By the 3rd century Christian schools not only maintained the learning of Greece—dialectics, physics, geometry, astronomy, philosophy, ethics—but added to these the study of the Scriptures, of God himself (or theology) and of piety. Such were the subjects taught in Origen's schools, first at Alexandria, then (A.D. 232) at Caesarea. The school of Lucian at Antioch became known for its historical emphases, that at Edessa for its concern for the Bible. The Nestorian school at Nisibis anticipated the medieval universities in holding its own property, enforcing its own disciplines under its own rules of behaviour and showing other signs of independence, including the exacting of a promise from students to reside at the school and to study. At Constantinople, although theological education in the east always kept itself free from state control, the patriarchal school maintained a friendly reciprocal relation with the state university which had no faculty of theology.

Following the collapse of Rome and its culture in the 5th century, monastic and episcopal (later cathedral) schools, providing for education from childhood to priesthood, not only preserved the heritage of the ancient world through the dark ages but also led to the establishment of over 50 universities in slightly more than three centuries prior to 1400, among them Bologna (the oldest, 1088), Paris, Oxford and Cambridge.

**The Reformation and After.**—Education in medieval times included grammar, rhetoric and dialectic (the trivium) and mathematics, music, geometry and astronomy (the quadrivium). In the 16th century Philipp Melancthon enlarged the trivium with Hebrew, Greek and Latin; the inclusion of theology followed. For the Reformers, as earlier for St. Thomas Aquinas, learning was of great importance. The Scriptures were their source of doctrine. The "priesthood of believers" opened the way to individual judgment which needed to be informed and the faithful required instruction to fulfill their new sense of obligation to preach to those outside the church.

Meanwhile the Church of Rome recognized that the Reformation had been caused partly by ignorance, superstition and lack of education among the clergy. At the Council of Trent, therefore, in 1546, legislation was enacted which provided for a liberal education plus professional priestly training for each diocese, permitting poor dioceses to combine, large dioceses to establish more than one seminary, but taxing the church to ensure a sound preparation for the clerical calling.

On the North American continent Harvard college, founded

in 1636, was designed to provide training for responsible service in both church and state but especially in the former. Modeled after Cambridge university, its course of study reflected medieval and Renaissance practices and continued the Reformation stress on biblical teaching and preaching. Thus, the high level of Reformation education was maintained in the new world.

**Changing Patterns.**—During the 18th century a candidate for the Protestant ministry in the British Isles or North America received little education beyond the arts degree to prepare him for his calling. If he did not attend college he would study privately in the home of a parish minister. Or he might pursue theological training in the Protestant universities on the continent of Europe. In 1721 Harvard began in America the differentiation of theological training from general education by the establishment of the Hollis chair of divinity. Yale followed with a similar step in 1756. However, a theological student usually took his "divinity" after completion of his A.B.; the A.B., intended for all, remained the most important part of his training. To the 20th century, both in Protestantism and Catholicism, a sound education in the liberal arts remained a proper foundation for ministerial and priestly studies. "We urge," said Pius XII in the encyclical *Menti Nostrae*, "that the literary and scientific education of future priests be at least not inferior to that of laymen who take similar courses of study."

Toward the close of the 18th century, however, various forces operated strongly further to separate education for the ministry from education for other callings. One of these was the differentiation of occupations in a more highly organized society, leading to the organization of medical schools (King's college [Columbia university], New York, 1767) and schools of law (Litchfield, Conn., 1784) which did not require a previous A.B. The age of reason had run its course and some theological schools were founded in reaction against the influences of 18th-century rationalism upon the universities. Revivalism, the expansion of frontiers, the growth of denominational consciousness accompanying rapid immigration and social stratification, and lively theological controversies all combined to produce a new movement, the creation of independent or separately organized theological schools.

In England, also, medical and legal studies were separated from the undergraduate universities and centred in London. For a time, academies designed for the preparation of Dissenting ministers who were barred from schools of the established church flourished. By the middle of the 19th century, however, these academies had declined and ministerial training became concentrated in theological colleges, many affiliated with universities. It was this pattern that prevailed in the British Isles after 1850. On the continent theological studies, almost entirely pursued in universities, tended to become more concerned with the scientific study of religion and, in Protestant circles, less involved in the equipment of the students for their special ministries.

In North America a school of the Dutch Reformed Church, begun in New York city in 1784, subsequently became the New Brunswick Theological seminary. The reasons for this important departure in theological education were most clearly stated in 1805 by John Mitchell Mason, founder of a less permanent seminary of the Associate Reformed (Presbyterian) Church. Anticipating emphases of a much later day, Mason insisted that the Scriptures be studied in their original languages; that students be encouraged to form independent judgments; that the whole person—body, mind and spirit—be simultaneously strengthened; and that the highest standards of comprehensive thoroughness and intellectual creativity be maintained against all hardened dogmatisms and considerations of expediency. By 1890 about 170 Protestant seminaries had been established, all to some extent indebted to Mason's ideas. Many of these insisted on at least a measure of administrative independence, a college course leading to a B.A. or its equivalent as a requirement for admission, and attendance at the seminary for three academic years of approximately 40 weeks each.

Meanwhile, beginning in 1791 when Archbishop John Carroll established St. Mary's seminary in Baltimore, Roman Catholicism developed new seminaries with the formation of new dioceses. By

1833 there were 7, by 1866 approximately 20 more and by 1945 over 250, some conducting studies at the high school and junior college level (six years), some at the senior college and specifically theological level (another six years), some working in both divisions. Some were under diocesan control, others were under religious orders, but all prepared young men exclusively for the priesthood.

The similarities between Roman Catholic and Protestant seminaries in the early 19th century are striking. Many, both Roman Catholic and Protestant, began as house schools in the home of the teacher or teachers. Gradually separate buildings and increased faculties appeared. Many were connected with a college or school. Plagued by inadequate financial resources, scarcity of students, lack of books and generally low intellectual standards and achievement, many survived for only a short time.

**After 1860.**—Although theological education tends to cling to the past more tenaciously than other disciplines do, it could not escape the influence of the vast changes that have made the modern world. The enormous increase in the study of the physical sciences, the historical-critical method of investigating ancient documents, the economic interpretation of history, the new psychology, the growth of secularization, the rapidly increasing population, the enlarged possibilities of communication, the practical interests of the western world, the threat of atomic warfare—all these and many more had their effect on seminaries and schools of theology that once were isolated from such concerns.

Two main purposes characterizing these schools were summarized in the distinction Edward Pusey made in 1832 when he said that the British educational system was best calculated to form ministers of the church while the German system could best impart knowledge. The priest or minister is taught to be a "parson" or person worthy to represent his calling and to be respected as an ambassador of Christ, a father to a family with which he has close touch. At the same time he is a "cleric" or one who can write—one who possesses the general and special professional knowledge that enables him to maintain and advance understanding of God's ways with man.

Partly, therefore, the problem of theological education is to meet the needs of the churches and of the "coming great church." In response to the expansion of the Christian movement, the increase of population and the interests of great ecclesiastical organizations, seminaries sprang up all over the world in great profusion. In Europe, where theology has been traditionally connected with a university faculty, the number of seminaries remained relatively constant, but in Asia, Africa and Latin America more than 200 Protestant and over 350 Roman Catholic seminaries, plus about a dozen Eastern Orthodox, had emerged by the mid-20th century. In the United States the 15 years after 1945 saw an increase in the number of Roman Catholic seminaries of more than 50% and in the United States and Canada the number of Protestant theological students more than doubled in the second quarter of the 20th century.

For Protestant theological schools, more than for Roman Catholic or Eastern Orthodox, there was in the 20th century, as in the 16th, a considerable expansion of the curriculum, which was generally divided into four main fields: biblical, theological or doctrinal, historical and practical. Although in Europe relatively few courses were introduced, in North America the wide diversity characteristic of the universities' offerings affected the seminary, especially in the fourth or practical field. Frequently courses were offered in the interpretation of culture and the arts, in the nature of the modern world in which the Christian church is set, in rival philosophies and in the understanding of human behaviour. Attempts were made to bring Christian insights of Scripture, theology and history to bear upon the pressing ethical problems of the modern era. Men were trained in the conduct of public worship, in the use of modern methods of communication, in the art of teaching and in the preparation and delivery of various forms of public address. To encourage the maintenance of high standards of theological education, Protestant seminaries in the U.S. and Canada began to meet in biennial conferences in 1918, and in 1936 organized the American Association of Theological Schools.

In reaction to the secularization of modern society, numerous Bible colleges or Bible schools appeared, only a few of which maintain studies at a predominantly postgraduate level. Bible schools generally do not provide the general education that the seminaries require and thus sometimes offer a short cut to the ministry; but not a few seminaries began as Bible schools.

Where theological education is under the control of the state or of a state church, as in Germany, Greece, Scandinavia, the Netherlands and England, the curriculum tends to be more traditional, with a heavy emphasis upon Scripture, its languages and the classical formulations of Christian theology. In Greece and in Sweden the majority of those enrolled in the theological faculties of the universities tend to become lay teachers rather than ordained ministers. Consequently, Greek Orthodoxy, for example, finds most of its theologians among the laity.

The government of theological schools or colleges varies widely from complete independence to direct control by a university, church or department of the state. Roman Catholic schools may be under the direction of diocesan authorities or of religious orders. In the United States and the countries of the "younger churches," there are a few Protestant interdenominational seminaries, and numerous schools in one way or another co-operate with each other. The pattern of a yoked college and seminary is receding in favour of an institution with its own board of trustees and a faculty which determines academic policy. Efforts are being made in many churches to acquaint the membership with the acute problems of the seminaries, their importance as intellectual centres of the church's life and the need to support them generously. Despite denominational rivalries, there are signs of increasing care in the location of new and the removal of older seminaries to ensure co-operation with other seminaries and universities.

Although the dual responsibility of theological schools to provide ministers for rapidly expanding churches and to maintain high standards of theological learning often causes tensions, on the whole this concern for both life and thought, both peoples and principles, both practice and knowledge is healthy. When the demands of the church are uppermost, seminaries tend to be located in places where a strong community life can be fostered and individuals nurtured in prayer, personal discipline, the church's lore and ritual and the denominational program. When the intellectual standards for the ministry are uppermost, preparation for the ministry is likely to be concentrated in university centres and in some way connected with the acquisition of an academic degree. Even in the schools with the strongest denominational ties, however, isolation is diminishing.

On the continent, where theology long insisted on its position as queen of the sciences and theologians were entrenched in university faculties, there has been a movement to establish church high schools, preacher seminars and other forms of auxiliary institutions designed to equip the ministry for its task. Throughout the world increasing stress is being put upon the theological education of the laity, reflected in the German *Kirchentag*—the annual meeting, since 1949, of the Evangelical church laity—and the establishment of over a score of lay academies, the majority in Germany.

**BIBLIOGRAPHY.**—The traditional prescriptions of the Holy See on clerical education are summarized in *Deus Scientiarum Dominus* (1931) and *Sedes Sapientiae* (1956). **THEOLOGY (ARTICLES ON):** see RELIGION (ARTICLES ON).

**THEOLOGY, CHRISTIAN**, a disciplined reflection upon the truth of Christian revelation, "the science of things divine" (Richard Hooker). The earliest use of the word "theology" in Greek referred to the critical interpretation of the classical myths—a sense that the word has sometimes had in Christian usage as

well. Therefore the history of the term "theology," which has engaged the attention of scholars during the 19th and 20th centuries, is, despite its interest, no reliable guide to the meaning of theology; in Thomas Aquinas, for example, "sacred science" is the common term for theology. A more useful introduction to the nature of theology can come from a general analysis of its place as a science, of its sources, and of its functions, followed by a brief delineation of how these three issues are understood in the major Christian groups.

### THEOLOGY AS A SCIENCE

An age that has become accustomed, so rapidly and so completely, to the use of the term "science" exclusively for the empirical investigation of the data of the natural world finds the application of this term to religion an anomaly. Nonbelievers regard such application as presumptuous, believers see it as a betrayal of the uniqueness of religious experience. Yet theology is fully entitled to be called "scientific" if by this one means that it has a prescribed function, a disciplined methodology and a rational structure.

The two other disciplines with which Christian theology has most often been compared and contrasted are philosophy and history. An obvious and common distinction between theology and philosophy is derived from the more basic distinction between reason (or experience) and revelation. Philosophy is a product of the natural reason and deals with the realms of reality that are accessible to reason; theology is charged with the interpretation of a truth that is revealed supernaturally. "Hence there is no reason why those things which are treated by the philosophical sciences, so far as they can be known by the light of natural reason, may not also be treated by another science so far as they are known by the light of the divine revelation. Hence the theology included in sacred doctrine differs in genus from that theology which is part of philosophy" (Thomas Aquinas).

But the very theology of Thomas Aquinas shows that this formal distinction between the tasks of theology and philosophy does not prevent a theologian from interpreting the data of revelation in one particular way because of his commitment to a particular philosophy. Dealing as it does with the nature of being and the rules of human thought, philosophy affects the work of the theologian throughout his system (and there were philosophical "systems" before there were theological ones). Therefore Christian theology has not been able to avoid philosophy even when it wanted to; although Tertullian and Martin Luther denounced the incursion of philosophy into Christian thought as a perversion, both found themselves obliged to draw upon philosophical sources for their exposition of Christian thought. But even the most philosophically inclined of theologians have been unable to bend the facts of Christian revelation into comfortable harmony with their metaphysics, for Christianity as a history, as a proclamation and as a sacramental life has refused to become completely malleable even in the hands of ancient Neoplatonists or modern Hegelians.

An awareness that the "Hellenization of the gospel" (Adolf von Harnack) resulted when theologians were overly attentive to the claims of philosophy has caused Christian thought in the 19th and 20th centuries to tie the work of theology more closely to that of history. Thus when Friedrich Schleiermacher defined dogmatic theology as "the science which systematizes the doctrine prevalent in a Christian Church at a given time," he made the task of the dogmatic theologian primarily a historical one; viz., of determining the doctrines that are prevalent and then of reflecting upon them in a systematic fashion.

The very concentration of Christian theology upon revelation—the account of God's dealing with the world through the history of Israel, through the saving career of Jesus Christ and through the establishment and development of the church—makes it a historical discipline. Yet the outcome of the historical preoccupation of theology has raised some fundamental questions about the propriety of identifying it so closely with historical research. For historical research has the result of making its data relative—relative to the processes of research themselves and relative to the age and culture in which they occurred. Historical study of the Bible,

for example, has related central elements of the creed, such as the virgin birth and the ascension of Christ, to the religious and mythological conceptions of the ancient world. The outcome has been to discredit the biblical narratives in the eyes of many, and even those who continue to regard these narratives as basically trustworthy have learned to recognize the historically conditioned character of biblical language and imagery. A simplistic equation of theological science with historical methodology is thus an absurdity on the face of it.

Equally absurd is the assertion that because theology does not conform to either philosophy or history it is fundamentally irrational and intuitive, more akin to poetry or song than to the orderly work of the intellect. As a protest against the excessive intellectualism of some theologians or periods in history, such a "theology of the heart" makes a valid point, but it is incapable of going on to do the work of theology, which is thus assigned by default to other disciplines, especially to philosophy and history. Ironically, the pietistic attack upon theology in the name of true religion may thus bring on the loss both of scientific theology and of true religion. Conversely, a scientific theology that knows its limits and that is open to the discipline that philosophy, history and other sciences can provide for it, even as it pays primary attention and yields fundamental loyalty to the data of revelation, may serve the cause of the "religion of the heart" more faithfully than does the anti-intellectualism of the enthusiast.

### SOURCES OF THEOLOGY

Because Christianity is a religion of revelation (however that term may be interpreted), Christian theology is derived from the sources of revelation. But the specification of these sources and of the connection among them has been the occasion for longstanding controversy both among the several Christian traditions (see below) and within them. Yet it is possible to describe some areas of agreement before charting the principal points of disagreement.

All Christian theologians would agree that the chief source of revelation, and therefore of theology, is the history of God's dealing with men, whose climax was the life, death and resurrection of Jesus Christ. Not only does this preclude any identification of Christian revelation with metaphysics and compel Christian thought to take history with utmost seriousness, as we have said, but it also determines the very structure of the response that theology gives to divine revelation. Christian doctrines are historical in their point of reference even when they are metaphysical or moral or liturgical in their subject matter and intent.

In Christian revelation, therefore, the career of Jesus does not consist in the disclosure of ontological structures that any intelligent man could have discovered for himself, nor in the pronouncement of home truths about life that belong to the common ethical heritage of the race. Christian revelation is basically an event: "And the Word became flesh and dwelt among us, full of grace and truth; we have beheld his glory, glory as of the only Son from the Father." The phrase "we have beheld his glory" is centrally relevant to the definition of the sources of theology. For the history of Jesus Christ is not directly accessible to those who were not his contemporaries; for that matter, even his contemporaries could not make sense of it. It was remembered and recited, celebrated and obeyed, by a community that believed itself called into existence by what Jesus Christ had been and done. Literary and historical research into the development of this collective remembrance has distinguished among various forms of narrative and recitation. Similarly, the history of the people of Israel was not set forth with the purpose of satisfying the curiosity of historical scholarship but for the edification and education of the people of the covenant. Any effort by theology to make use of this history must be sensitive to the processes by which the Jewish people and the Christian community assembled their recollections of the events by which they knew themselves to have been constituted.

The principal repository of the history of revelation, to which theology looks as its source, is the Bible. All Christian theologians are concerned in one way or another to make their theologies bib-

lical, vary though they do in the content and intent of their interpretation of Scripture. So divergent are these renditions that the reader of theology is often led to the conclusion that a mere acknowledgment of the biblical basis of theology is meaningless, since everyone finds in the Bible what he pleases. In fact, however, such a counsel of despair ignores the concrete influence of the Bible upon the teaching and the language of an astonishing variety of theologians. Often—not always, but often—their divergences are not between *the* theology of the Bible and an antibiblical theology but between one aspect of biblical teaching and another. The Bible is more comprehensive than the systems of the theologians. At the same time, the faithfulness of a particular theology to its biblical source cannot be gauged statistically, for it is just as possible to express biblical doctrine in nonbiblical language as it is to use the terminology of the Bible for expressing notions that are utterly foreign and even hostile to the message of the Old and New Testaments.

From the history of Christian theology it is also evident that although all theologians have appealed to the Bible as a source for their theology, the directness and the freshness of their use of it have fluctuated considerably. Both Roman Catholic and Protestant theologians in the 17th century, for example, claimed the authority of the Bible for their systems, but the systems of both were in fact shaped by the controversies of the Reformation and Counter-Reformation. The resurgence of biblical theology during the 20th century in both traditions transformed both Roman Catholic and Protestant theology, creating noticeable areas of new agreement amid continuing and often deepening disagreement.

No disagreement has been more pervasive than that over the relation of the Bible to other possible sources of theology, particularly the teaching of the church and the doctrines of the natural reason. Although Protestant theology came to acknowledge that there was a church before there was a Bible and that the Bible is intended to be read and studied in the context of the church, it regarded the idea of an infallible living magisterium as an affront to the authority of the Bible. Roman Catholic theology meanwhile came to acknowledge the primacy of the authority of Scripture more clearly than it had during the controversies that followed the Protestant Reformation, but it still insisted that the only solution to the confusion of theological voices brought on by the anarchy of an appeal to "the Bible and the Bible alone" is the acceptance of a normative tradition in the church, embodied in the ongoing life and teaching of the entire body of the faithful but safeguarded and articulated in the teaching authority of the pope.

Debates within Protestant theology made the dispute over the place of reason in theology much more confusing than the controversy over tradition. Protestant liberalism made more substantive use of reason and of philosophy than Roman Catholic theology ever had, but the theological movement associated with the name of Karl Barth attacked even the Thomistic interpretation of natural theology as a menace to truly biblical teaching. (See BARTH, KARL; NEO-ORTHODOXY; LIBERALISM, THEOLOGICAL.)

Yet even on the question of the place of reason in theology the differences tend to be differences of degree and of emphasis, for no theologian who lays claim to the name "Christian" would assign the central and normative place in his theology to any source of knowledge about God except divine revelation, and none would assign to the Bible a subordinate role in the determination of what the revelation means.

### FUNCTIONS OF THEOLOGY

As a churchly science, theology is intended to interpret and to serve the life of the church. This does not mean that it is directed only at those who are professing members of the Christian community, for since it claims to be based upon the revelation of the God who is the Giver of every good and perfect gift, it includes in its purview all the creatures of God and in its address all who are created in the image of God. Simply as an exercise in rational thinking and systematic exposition, Christian theology deserves the attention of any serious student. Yet even in its address to "those without," Christian theology speaks for the community of the church. While there has been great variation among

theologians in their enumeration of the branches of theology, most theologians would find it possible to make their point under one or more of the following rubrics: speculative theology, historical theology, systematic theology, practical theology.

**Speculative Theology.**—By "speculative theology" is meant the whole effort of classical Christian theologians to measure as precisely as possible the capacities and the limits of the unaided human mind in relation to the truth of revelation. One purpose of this effort has traditionally been the apologetic one of refuting objections to the Christian faith and of demonstrating its harmony with human knowledge and thought. Despite this obvious evangelistic purpose, speculative theology has in fact been directed more to believers than to nonbelievers. It is, in the classic phrase of Augustine and Anselm, "faith in search of understanding." Thus Anselm set out to prove the existence of God to readers who were baptized members of the church, and Thomas Aquinas wrote a *Summa contra Gentiles* when there were very few *Gentiles* (i.e., pagans) who could or would read his treatise. The Protestant Reformers were critical of the role that speculative theology had played in the middle ages, not because they denied that even without revelation something about God is knowable but because they accused this natural, speculative theology of watering down the biblical and evangelical content of theology. In the period of the Enlightenment, however, both Protestant and Roman Catholic theology were obliged to reopen the question of speculative theology, and the consequences of Kant's critiques and of modern science made the issue a live one again. The theological history of the first two-thirds of the 20th century persuaded most theologians that if they were ever to find an audience again, either within or without the church, they would have to interpret the relation between natural and revealed theology in a way that took account of the discoveries and the conclusions of modern thought.

**Historical Theology.**—Although the term "historical theology" is usually confined to the study of church history or even of the history of Christian thought, both the subject matter and the methods of biblical study qualify it for inclusion under this title. The specialization of modern scholarship has led to a division of labour also among theologians, especially in biblical and historical research. Each branch of this research has its counterpart in the nontheological disciplines. Thus biblical scholarship has been shaped by the methods and results of research in classical and near eastern history and philology, and some of the most important discoveries in church history have come from scholars working in political, social and literary history.

One consequence of the division of Christendom has been the concentration of theologians from certain Christian groups upon certain bodies of historical material. Not only are the founders of the several denominations almost exclusively the concern of the theology of those denominations—so that, for example, Lutherans often write systematic theology under the guise of historical research on Luther—but even the periods of church history that are presumably the common property of several traditions are often neglected by some of them. Until the end of the 19th century, the study of the Hebrew and Greek Scriptures in Roman Catholic theology was often an imitation of Protestant scholarship, while among Protestant theologians the study of the Church Fathers was largely confined to Anglicans and Lutherans, both of whom fell behind their Roman Catholic colleagues during the first half of the 20th century. Because of the decisive role of Scripture and tradition in Christian theology, historical theology in one generation may frequently determine the course of systematic theology in the next, just as historical theology often receives its initial stimulus from dogmatic theology or from church life and worship.

**Systematic Theology.**—No branch of theology is less uniformly designated than the one charged with the exposition and systematization of Christian doctrine. Sometimes it is simply called "theology" in a narrower sense than the one employed here (although in a still narrower and stricter sense "theology" means only the doctrines about God and Jesus Christ). Roman Catholics often refer to systematic theology as dogma; the older Protestant term, revived by Karl Barth, was *dogmatics*. (See *DOGMA*.) Protestants generally speak of systematic theology, sometimes of

constructive theology. These variations reflect both the influence upon theological work of the divided state of Christendom and the uncertainty of many theologians about dogma and tradition.

The method of systematic theology is no more a matter of general agreement than is its content. Even where the tradition of the church is accorded a normative function, the method of systematic theology must still choose from among several options, including a predominantly biblical, a more explicitly dogmatic and an apologetic or speculative method of giving structure to the stuff of tradition. Of itself, this stuff does not yield a systematic structure from which theology can acquire the architectonic balance and precise formulation that are so admirable in the *Summa* of St. Thomas or the *Institutes* of John Calvin. To the familiar triad of Scripture, tradition and philosophy must be added a fourth component: Christian experience. Both in the mystical theology of the Orthodox and Roman Catholic traditions and in the theology of feeling made famous by the Protestant theologian Schleiermacher, the personal relation of the theologian to God becomes a fundamental part of his theological procedure, although neither the great Christian mystics nor Schleiermacher claimed that experience could displace Scripture and tradition as the norms of the authentically Christian in Christian theology.

**Practical Theology.**—Each branch of theology points beyond itself to the Christian church, out of whose life it emerges and to whose edification it is devoted. In this sense all theology is "practical theology," for no theology is an end in itself. Yet the location of most theological work in the seminaries of the church, where it supports the training of the Christian clergy, and the demands of the liturgical, educational and evangelistic life of the church, have made it necessary for faculties of theology to develop departments that specialize in the application of theology to the practice of the ministry. Preaching, teaching, worship and pastoral counseling may all claim a place in the study of theology.

It would be an oversimplification, however, to dismiss these areas as "mere techniques," whose intellectual content is less demanding and whose methodology is less rigorous than those of the "content disciplines." For it is a fact substantiated by the history of theology that some of the most profound insights into the meaning of the Bible and the mysteries of the Christian faith have come not from the abstractions of the academicians but from the practical work and experience of the pastor, bishop and missionary. Neither Paul nor Athanasius nor Augustine was a professor; all were engaged in the proclamation of the faith to believers and nonbelievers and in "the care of all the churches." Characteristically, Protestant theology is ready to admit this especially about the preaching ministry of the church, while Orthodox and Roman Catholic theology will stress the great contributions made by the liturgy to the development of dogma. Both would acknowledge, in the words of a Greek Church Father, that "practice is the basis of theory," and both would insist that this does not invalidate, but only reinforces, the function of the theological scholar.

## THEOLOGY IN THE CHRISTIAN CHURCHES

**Roman Catholicism.**—When Roman Catholic thought, following Thomas Aquinas, refers to theology as "sacred science," it speaks out of the conviction that theology is not merely one science among others but is the queen of the sciences. Within its assigned area of responsibility it addresses the other sciences and retains its independence of them. Because Roman Catholic theology worked out its most impressive definition of theology as a science in a vigorous debate over the philosophy of Aristotle during the 13th century, it has sometimes been reluctant to consider the implications of more recent systems of thought for the scientific character of theology. An immensely productive advantage of Roman Catholic theology over Protestant thought has been its conviction that theology is indeed a *scientia*, a way of knowing, and that therefore the intellect has a legitimate and a necessary place in the life of faith, both for the church and for the individual. From this conviction has come the readiness, in spite of some initial hesitation, to correlate the knowledge given by the faith with other forms of knowledge, as well as the confidence that theology does not have to apologize for its claims. This does not mean that

according to Roman Catholicism revelation is "propositional" in its primal content; it does mean that language about revelation must be as precise and in this sense as rational as language about the Homeric epics or about nuclear fission.

In part this confidence stems from the Roman Catholic view of the sources of theology. The doctrine of the infallibility (*q.v.*) of the pope is sometimes interpreted by its critics and even by its proponents as though the pope were the only real theologian in the church. What it implies is rather that Jesus Christ did not leave his church bereft of the teaching authority that he himself had exercised in the days of his presence on earth, but he established the office of the apostles in and for the church, with the apostle Peter and his successors as the first among the incumbents of the apostolic office. Through this apostolic office he continues to rule and to instruct the church.

Roman Catholic theologians formulate the relation between this ongoing office and the Bible in different ways, but the consensus of the tradition itself is on the side of the contention that revelation closed with the death of the last apostle, that all revelation is contained implicitly in the Bible and that the task of the teaching office of the church is to make the revelation explicit. The dogma of the church is not a second source of revelation in the sense that it discloses something not given to the apostles and not set down in Scripture, but it is the authoritative interpretation of the revelation in Scripture; to Roman Catholic theology it is unthinkable that the interpretation of the Bible should conflict with the authoritative teaching of the church, whose spokesman is the pope.

Because of its distinctive conception of the nature of the church, Roman Catholic theology also interprets the functions of theology in a special way. For example, ascetical theology, which deals with the nature and the implications of discipline in Christian life and thought, becomes a special field. There is also a special function for "mystical theology," which examines the uniqueness of Christian contemplation and analyzes the connections between the vision of God granted to the experience of such contemplation and the doctrines set forth in Scripture and dogma. The Roman Catholic understanding of moral theology sets down the teachings of both natural law and revelation about ethical issues and applies them within the framework of the teaching church. In some periods of Roman Catholic history, this application has been responsible for the development of an elaborate casuistry (*q.v.*) in the handbooks of Roman Catholic moral theology, but it is a mistake to identify this detailed weighing of moral alternatives as the Roman Catholic idea of Christian ethics. An even more common mistake is to identify Roman Catholic theology exclusively with the speculative and philosophical doctrines of Thomism (*q.v.*), without giving proper due to the biblical and the liturgical components of all Roman Catholic theology, even and especially the theology of Thomas Aquinas. Not because of its formidable philosophical apparatus, but because of its content as the exposition of divine revelation, Roman Catholic theology claims the right to be regarded as "sacred science."

**Eastern Orthodoxy.**—The Eastern Orthodox view of the scientific character of theology, the Orthodox definition of the sources of theology and the Orthodox conception of the functions of theology are all determined by the place that Orthodoxy assigns to the tradition of the church. Therefore the scientific work of theology in Orthodoxy consists largely in the study of the Fathers of the Church. At times this has meant nothing more than the compilation of apposite quotations from the Fathers and the councils on the various topics of Christian teaching; such a compilation was intended to serve as the basis for oral instruction and exposition. But in part through the application of methods of research developed in the west, Eastern Orthodox scholarship has also given theology a systematic character. Sometimes under the influence of Thomism and sometimes because of the writings of Protestant theologians and philosophers, Russian Orthodox theology during the 18th and 19th centuries created systems of doctrine that strove to be faithful to Orthodox tradition while recasting it in a Protestant mold; none of these systems achieved permanent recognition among Orthodox theologians. Like Roman Catholicism, Orthodoxy designates tradition as a source and norm of theology, but it

is less definite in its specification of the locus of authoritative tradition. The ancient Fathers and the councils of the undivided church belong to tradition, but so does the liturgical piety of the church. No one national and autocephalous church, whether Greek or Russian, and no one see or patriarchate has the right to determine for all of Orthodoxy what is the authentic tradition.

The severe restrictions placed upon the Orthodox churches during the modern history of eastern Europe and Asia Minor drastically curtailed their theological productivity. The flowering of a "lay theology" in the Russian Orthodoxy of the 19th century came to an end with the Russian Revolution, while the emancipation of the Greek and Balkan churches early in the 19th century did not serve to stimulate any large-scale renaissance of work in theology. In the United States and in France, Orthodox communities of Russian and Greek origin were beginning at the middle of the 20th century to take up serious theological research and writing.

**Protestantism.**—The place of the theological faculties in the universities of Germany and Great Britain has perhaps done more than any other single factor to shape the Protestant interpretation of theology as a science. The very term *wissenschaftliche Theologie* ("scientific theology") as a designation for theological research is an index of the equation of "scientific" with "scholarly." As has been pointed out earlier in this article, philosophy and history are the two disciplines that have done most to make theology a *Wissenschaft*. The systematization of the theology of the Protestant Reformers, which began during their own time but achieved massive proportions in the 17th century (*cf.* ORTHODOXY, PROTESTANT), was accomplished with the aid of Aristotelian philosophy. The philosophies of Descartes, Leibniz and especially Christian Wolff were widely held during the 18th century, but the influence of Immanuel Kant upon Protestant theology was so pervasive throughout the 19th century that he has been termed, not without justification, "the philosopher of Protestantism," at least of German Protestantism and of the American Protestant theology that has been patterned after German models.

Less generally recognized than Kantian philosophy as a presupposition of Protestant theology during the 19th century is the rise of the historical method, by means of which much of Protestant theological work sought simultaneously to draw upon the resources of the Christian past and to justify itself within the university as genuinely *wissenschaftlich* discipline. From this came, for example, the permanent achievements of Protestant scientific theology in the field of the textual criticism of the Bible.

Another motivation for textual criticism was, of course, the Protestant principle of biblical authority. From the writings of the Reformers and from the confessional statements of the several branches of Protestantism it is possible to construct the theory that "the Bible, and the Bible alone, is the religion of Protestants." Tradition, creed and dogma are all said to be derived from the Bible and therefore not to be put on a par with it. The practice of the Reformers, of the Reformation confessions and of subsequent Protestant theology is not, however, a unilinear application of this principle. For the theology that was derived from Scripture bore a striking resemblance to the tradition of the orthodox creeds. Both the ecumenical movement and the results of scholarly research into the Bible and church history caused Protestant theology during the first half of the 20th century to restate its traditional opposition to tradition in a way that allowed to tradition a positive (if not, in the Orthodox or Roman Catholic sense, an authoritative) place as a source of Christian doctrine. As has already been pointed out, the theology of Schleiermacher put into formal statements the conviction of many Protestants that the experience of Christians and of the truly Christian community should be a decisive factor in theology also. The multiplicity of Protestant denominations and of theological trends within those denominations meant that this formal agreement among Protestants about the sources of theology did not produce any consensus, at least until the rise of the ecumenical movement (*q.v.*).

The denominational context of Protestant theology also helps to explain how the functions of theology are interpreted. Thus the theological controversies of the Reformation and post-Reformation periods imposed upon the systematic theology of the age a

strongly polemical orientation. Even the biblical and historical scholarship of Protestant theology has had a share in polemics; thus the *Magdeburg Centuries*, one of the earliest works of Protestant historiography, were intended to prove that Roman Catholic claims to continuity with the early church lacked historical ground.

With the coming of the ecumenical movement, the atmosphere of polemics changed drastically. Shaped by the same biblical and historical research and confronted by the same existential situation both within and without the churches, theologians of various denominations discovered that they had more in common than the polemical stance of their several traditions had acknowledged. In the area of practical theology, the needs of the churches and the rise of new secular disciplines (especially of the social sciences) called forth a reappraisal of the conventional categories. New fields like the psychology of religion and the sociology of religion came out of this reappraisal, with consequences that reached far into the traditional fields like church history and systematic theology. Philosophy of religion or even philosophical theology became the characteristically Protestant way of handling the material of speculative theology. In the 19th and 20th centuries the study of non-Christian religions became a permanent part of the corpus of theological research in many Protestant centres.

**Theology in the Present and the Future.**—The general decline in the prestige of the Christian church during the modern and "postmodern" eras affected theology as well, causing it to put forth its claims with greater modesty and to construct its systems with less boldness. Impatience with the details of theology, expressed so often by both clergy and laity in the name of "the real business of the church," was sometimes replaced by the recognition that the only alternative to theology is bad theology. If the church found theology desirable when Christianity counted for much in the western world, it would find theology indispensable when Christianity had lost its place as the dominant ethos of its culture. In this sense, many Christian theologians at the middle of the 20th century believed that the most productive age of Christian theology still lay in the future. See also references under "Theology, Christian" in the Index.

**BIBLIOGRAPHY.**—At least some of the writings of most major theologians of Christian history have been translated into English; these translations are listed in the bibliographies of the articles on theologians and denominations. *The Library of Christian Classics* contains many such translations from the earliest Fathers to the Protestant Reformers. Histories of Christian doctrine, such as those by Joseph Tixeront, A. von Harnack and Reinhold Seeberg, often provide a helpful introduction to the study of theology. Books such as John Macquarrie, *Twentieth-Century Religious Thought* (1963), summarize many different trends, and sets like *The Twentieth Century Encyclopedia of Catholicism* and *The Library of Constructive Theology* make possible a study of particular issues and problems. (J. J. P.N.)

**THEOPHANES** CONFESSOR (c. 752–817), canonized by the Orthodox Church, Byzantine historian whose work is particularly valuable for the sparsely documented 7th and 8th centuries, as it draws on sources no longer extant, belonged to a noble and wealthy family. He married and later entered the monastery *tou megalou Agrou*, which he had founded at Sigriane in Bithynia. A vigorous opponent of the iconoclast policy of Leo V (813–820), he was imprisoned on Samothrace, where he died. His *Chronographia* covers the period from Diocletian's accession (284) to that of Leo V (813), and it was written at the instigation of his friend George the Syncellus to continue the latter's own unfinished chronicle. It is arranged by years, giving tables of Byzantine rulers, and also of the Persian kings, the Muslim caliphs, and the ecclesiastical heads of Rome, Constantinople, Antioch, Alexandria, and Jerusalem. It was translated into Latin (c. 873–875) by Anastasius, the papal librarian, and was used extensively by later Greek and Latin chroniclers.

*Theophanes Continuatus*, a work by various hands known also as the *Scriptores post Theophanem*, was originally commissioned by Constantine VII Porphyrogenitus (q.v.), and this part consists of four books (813–867), together with a fifth on Basil I (867–886) written by Constantine VII himself. The work was subsequently enlarged by a sixth book, which probably covered the period 886–963 (book vi in its present state breaks off at 961).

**BIBLIOGRAPHY.**—Critical edition of *Theophanes Confessor* by C. de

Boor, 2 vol. (1883–85), including Anastasius' version. *Theophanes and Theophanes Continuatus*, ed. by I. Classen—I. Bekkerus in the *Bonn Corpus*, 3 vol. (1838–41) and in J. P. Migne, *Patrologia Graeca*, vol. 108–109 (1861–63). German trans. for years 717–813 by L. Breyer, *Bilderstreit und Arabersturm in Byzanz* (1957). See also K. Krumbacher, *Geschichte der byzantinischen Literatur*, 2nd ed., pp. 342–349 (1897); G. Moravcsik, *Byzantinoturcica*, vol. 1, 2nd ed., pp. 531–537, 540–544 (1958); G. Ostrogorsky, *History of the Byzantine State*, pp. 79–80, 130, 187 (1956). (J. M. Hy.)

**THÉOPHILE**; see VIAU, THÉOPHILE DE.

**THEOPHILUS, SAINT**, bishop of Antioch about A.D. 180 (his chronological sketch of the history of the world ends with the death of Marcus Aurelius in that year), is known from his three apologetic treatises *To Autolytus*, preserved in a single 11th-century Greek manuscript. The first deals with Christian faith in God and in the resurrection of the dead; it may be based on catechetical instructions. The second contains theological criticism of Greek religion, philosophy and poetry, followed by a "typological" commentary on Gen. i, 1–iii, 19. The third attacks pagan writers and "proves" that Christian teaching is both better and older than that of all other peoples.

Theophilus tried to create a theology by interpreting the Bible (especially the Old Testament) in relation to contemporary rhetoric and eclectic philosophy. He gives extensive quotations from Hellenistic anthologies of poetry and philosophy, as well as from the Jewish Sibylline Oracles. Theophilus is the first Christian known who defined faith as necessary in any human activity (i, 8; cf. Cicero, *Lucullus* 109); the first to use Skeptical "modes" in attacking pagan religion; and the first to speak of the dignity of man (ii, 18). He is the earliest writer who mentions the inspiration of New Testament writings (iii, 12; cf. ii, 22), the triad of God, his Word and his Wisdom (though with man they form a tetrad; ii, 15), and the (Stoic-Philonic) immanent and expressed Word of God (ii, 10, 22; see *Logos*).

Theophilus emphasizes man's free will and his duty to keep God's law; thus he stands between the older Jewish Christianity and Greek patristic thought. Theophilus influenced Irenaeus, Tertullian and Novatian, but was later forgotten.

Nothing is known of his life, though in the 4th century he was mentioned by Lactantius and by Eusebius. His work was first published by Johannes Frisius in 1546. The best edition is that of J. C. T. Otto (1861). (R. McQ. G.)

**THEOPHILUS** (d. 842), Byzantine emperor from 829 to 842, son of the Amorion Michael II, was a cultured man whose tutor was the iconoclast scholar John the Grammarian. He was strongly opposed to those who venerated icons, and they were persecuted when John the Grammarian became patriarch in 837. Throughout his reign Theophilus was engaged in war with the Muslims. He failed to drive them out of Sicily, and in 831 Palermo fell. On the eastern front intermittent warfare for several years was followed by a determined drive by Muslims led by Caliph Mutasim into the heart of Asia Minor. In 838 Ankara was taken, followed by the capture of Amorion, and only after Theophilus' death on Jan. 20, 842, were the Byzantines able to retrieve their position. Nevertheless Theophilus' reign saw administrative reorganization both north of the Black Sea (the theme of Cherson) and in Asia Minor. He was much influenced by the contemporary civilization of Baghdad, and like Harun al-Rashid he was said to have wandered about his capital informally, listening to his subjects' complaints. In spite of his heretical iconoclast views, he was a popular figure who survived in later Byzantine literature as the type of the just ruler.

**BIBLIOGRAPHY.**—G. Ostrogorsky, *History of the Byzantine State* (1956); J. B. Bury, *History of the Eastern Roman Empire* (1912); A. A. Vasiliev, *Byzance et les Arabes*, vol. 1, ed. by H. Grégoire and M. Canard (1935); H. Grégoire in *Cambridge Medieval History*, vol. 4, ch. 3, new ed. (1966). (J. M. Hy.)

**THEOPHILUS** (probably also ROGER OF HELMARSHAUSEN) was the author of *De diversis artibus*, an exhaustive account (probably written in northwest Germany between 1110 and 1140) of the techniques of almost all the contemporary crafts of the first half of the 12th century.

From his writings it can be deduced that Theophilus was a German monk of the Benedictine Order and that he was a practis-

ing craftsman. In one manuscript (Vienna, Nationalbibliothek Hs.2527) he is designated "Theophilus qui est Rugerus," and he may have been the celebrated German metalworker Roger of Helmarshausen (also a monk), who was responsible in 1100 for a portable altar now in the cathedral treasury at Paderborn. Considerable interest is shown by Theophilus in the techniques of metalwork, but he also discusses the crafts of wall painting, manuscript illumination, stained glass, and ivory carving. The work is divided into three books, and the introduction to each is of interest in reflecting the attitude to his art of a 12th-century practising craftsman who was also an educated person. It contains the earliest references in Europe to paper and to oil painting.

**BIBLIOGRAPHY.**—Definitive Latin text with English translation and general discussion in C. R. Dodwell's edition (1961); translation with useful illustrations by J. Hawthorne and C. S. Smith (1963); for technical information on the metalwork, W. Theobald's edition of Book 3 (1933) is still invaluable. (C. R. D.)

**THEOPHRASTUS** (371/370–288/287 B.C.), Greek Peripatetic philosopher, was born at Eresus on the island of Lesbos and went to Athens to study under Aristotle. The latter designated him as head of his school, the Peripatos, when he himself retired to Chalcis (322/21). It was under Theophrastus that the Peripatetic school was frequented by the highest number of pupils and auditors.

Apart from Eudemos of Rhodes, Theophrastus was the only Peripatetic who embraced Aristotle's philosophy to its full extent—metaphysics, physics, physiology, zoology, botany, ethics, politics, the history of culture, etc. His general tendency was to strengthen the systematic unity of those subjects and to reduce the transcendental or Platonic elements of the whole doctrine.

Little has been preserved of Theophrastus' works. The principal remains are nine books *On the History of Plants* and six *On the Causes of Plants*. Smaller treatises extant under his name deal with fire, winds, signs of weather, scents, sensations, and other subjects; but their authenticity is in part contestable. The famous *Characters* consists of brief and vigorous delineations of moral types developed from studies that Aristotle had made for ethical and rhetorical purposes; this is the work on which La Bruyère's masterpiece was based. In his *Ethics*, known from the assaults of the Stoics, Theophrastus distinguished, as Aristotle had done, a plurality of virtues with their relative vices and acknowledged a certain importance to external goods.

Theophrastus' *Doctrines of the Natural Scientists*, as reconstructed by H. Diels in *Doxographi Graeci* (1879; reprinted 1929), provides the foundation of all history of ancient philosophy.

The works of Theophrastus were edited by F. Wimmer (1854–62); the *Characters*, by H. Diels (1909). There is an English translation of the *Characters* by Sir R. Jebb, with introduction and notes (1870; new ed. by J. E. Sandys, 1909); another edition and translation, by J. M. Edmonds, is in the "Loeb Classical Library" (1946). For the extant fragments of the *Metaphysica* of Theophrastus, see the edition by W. D. Ross and F. H. Fobes (1929). See also references under "Theophrastus" in the Index.

(F. Wl.)

**THEOPHYLLINE:** see PURINES.

**THEOPOMPUS** OF CHIOS (b. c. 380 B.C.), Greek historian and rhetorician, whose *Philippica*, though lost in original, has survived through the work of later writers to form one element in the tradition concerning the reign of Philip II of Macedonia. He was born at Chios and in early youth seems to have spent some time at Athens, along with his father, who had been exiled because of his sympathies with Sparta. There he became a pupil of Isocrates, and rapidly made great progress in rhetoric. According to Cicero, Isocrates said that Ephorus required the spur but Theopompus the bridle: he once won a prize for oratory in a contest in which Isocrates himself was taking part. It is said to have been the advice of his teacher that determined his career as a historian—a career for which he was peculiarly qualified by his inherited wealth and his wide knowledge of men and places.

Through the influence of Alexander the Great, he was restored to Chios about 333, and figures for some time as one of the leaders of the aristocratic party in his native town. After Alexander's death he was again expelled and took refuge with Ptolemy in

Egypt, where he appears to have met with a somewhat cold reception. The date of his death is unknown.

The works of Theopompus were chiefly historical. They included an epitome of Herodotus' *History* (the genuineness of which is doubted), the *Hellenica*, the *Philippica* (history of Philip of Macedon), and several panegyrics and hortatory addresses, the chief of which was the letter to Alexander. The *Hellenica* treated of the history of Greece, in 12 books, from 411 (where Thucydides breaks off) to 394—the date of the Battle of Cnidus. Of this work only a few fragments survive: the attribution to it of the important historical fragment known as *Hellenica Oxyrhynchia* or "the Oxyrhynchus historian" (first published by B. P. Grenfell and A. S. Hunt, *The Oxyrhynchus Papyri*, vol. v, no. 842, 1908) did not win acceptance. A far more elaborate work was the *Philippica* in 58 books. In this Theopompus narrated the history of Philip's reign (359–336). His narrative included not only moral and political discussions but also digressions on the names and customs of the various races and countries of which he had occasion to speak, which were so numerous that Philip V of Macedon reduced the bulk of the history from 58 to 16 books by cutting out those parts which had no connection with Macedonia. It was from this history that Pompeius Trogus (of whose *Historiae Philippicae* the epitome by Justin is extant) derived much of his material.

In spite of some extravagance both of style and judgment, examples of which can be seen in the extant fragments, it seems likely that Theopompus was the most interesting and considerable of all the Greek historians who are "lost."

**BIBLIOGRAPHY.**—Fragments in F. Jacoby, *Die Fragmente der griechischen Historiker*, vol. ii, B and D, no. 115 (1929–30) and vol. ii, A, no. 66, for the text of *Hellenica Oxyrhynchia*. On the attribution of the "Oxyrhynchus historian," see, besides Grenfell and Hunt cited in text, E. Meyer, *Theopomps Hellenika* (1909); F. Jacoby in *Nachrichten der Gesellschaft der Wissenschaften Göttingen* (1924); H. Bloch in *Harvard Studies in Classical Philology*, suppl. vol. i (1940). See also A. Momigliano, in *Rivista di filologia* (1931 and 1935); K. von Fritz, in *Antike und Abendland* (1954); H. D. Westlake, in *Historia* (1954); R. Laqueur in Pauly-Wissowa-Kroll, *Real-Encyclopädie der classischen Altertumswissenschaft*, vol. v, 2nd series, col. 2176 ff. (1934).

(G. T. Gh.)

**THEORELL, AXEL HUGO TEODOR** (1903– ), Swedish biochemist, was awarded the 1955 Nobel Prize for Medicine for his discoveries concerning the nature and mode of action of oxidation enzymes. He was born at Linköping on July 6, 1903. After taking his M.D. degree at Stockholm in 1930, he began general practice; but an attack of poliomyelitis left him crippled, and he decided to devote himself to research. He worked at Uppsala University (1932–36) and also studied in Germany while holding a Rockefeller fellowship. In 1937 he was appointed director of the biochemical department of the Nobel Institute, Stockholm.

In 1934 Theorell produced in pure form the so-called old yellow enzyme (i.e., the first known of this group), which influences combustion in living cells. He later divided the enzyme into the coenzyme (riboflavin phosphate) and the apoenzyme (pure protein). He was the first to produce pure myoglobin, the red colouring substance of muscle, and he devised a method of blood examination that came to be widely used in Sweden as a test for drunkenness.

(W. J. Br.; X.)

**THEOREM**, a term used in mathematics to represent a proposition (*q.v.*) that is to be demonstrated. In geometry, a proposition is commonly considered as a problem (a construction to be effected) or a theorem (a statement to be proved). For example, the statement: "If two lines intersect, each pair of vertical angles are equal" is a theorem. The so-called fundamental theorem of algebra asserts that every rational integral equation has at least one root. The Greeks also recognized a proposition lying between a theorem and a problem, the *porism* (*q.v.*).

See BINOMIAL THEOREM; FERMAT'S LAST THEOREM; REMAINDER THEOREM. For related terms see also AXIOM; HYPOTHESIS; POSTULATE.

**THEORY** has various meanings in ordinary speech and in science. It may be contrasted with practice as unverified speculation. It may also be used to signify any hypothesis, whether confirmed or not, or may be restricted to hypotheses that have been so strongly confirmed as to become part of the accepted doctrine

of a particular science. In its best use, it signifies a systematic account of some field of study, derived from a set of general propositions. These propositions may be taken as postulates, as in pure mathematics (theory of functions, etc.), or they may be principles more or less strongly confirmed by experience, as in natural science (theory of heat, electromagnetic theory). There may be rival theories in a particular field (e.g., in psychology) differing in their selection of principles or in the emphasis laid on particular principles.

As a science develops, the part played by deductive theory in it tends to become more and more important. See *HYPOTHESIS*; *SCIENTIFIC METHOD: The Role of Hypothesis*; *EXPLANATION*; *INDUCTION: Induction and Hypothesis*. (L. J. R.)

**THEOSOPHY**, those forms of philosophic and religious thought which claim a special insight into the divine nature and its constitutive moments or processes (from Greek *Theos*, "god," and *sophia*, "wisdom"). Sometimes this insight is claimed as the result of the operation of some higher faculty or some supernatural revelation to the individual; in other instances the theosophical theory is not based upon any special illumination but is simply put forward as the deepest speculative wisdom of its author. But in any case it is characteristic of theosophy that it starts with an explication of the divine essence and endeavours to deduce the phenomenal universe from the play of forces within the divine nature itself.

**General Theory.**—Theosophy claims to derive its significant data by way of intuition or through revelation from seers or masters. Thus it does not rely on ordinary observation or logical reason to the same degree as does most philosophical thought. Yet it often appeals to the "superior" or "higher" reason, and it should not be thought of as antirational. It is more closely related to religion than to philosophy in the usual Western sense of the term philosophy and is more at home with traditional Indian modes of thought than with Greek-European, since Indian thinkers as a rule do not draw sharp lines between religious and philosophical inquiry.

Theosophy generally arises in connection with deeply felt religious needs (for wholeness, blessedness, vision of God, etc.) and is thus one expression of religious aspiration. Accepting the testimony of religious experience that the present world lies in a state of imperfection, if not "fallenness," theosophy seeks to give an account of this state of things while pointing the seeker on to an experience of actualization on a higher plane of his being. Theosophical systems are thus concerned with the problems of metaphysical, natural, and moral evil, and in general find it possible to subordinate evil to good in a monistic frame of reference or in a philosophy of nondualism. (The Sankhya philosophy, one by-product of ancient brahmanical speculations in India, is an exception to this rule, since it posits an ultimate metaphysical dualism of *purusha*, or spirit, and *prakriti*, or nature.)

India has been the mother of most theosophical speculations. They are reflected in the systems known as Brahmanism, upanishadic thought and the Vedanta, Sankhya, and Yoga systems (see *INDIAN PHILOSOPHY*). These systems, along with the more popular sectarian movements of Hinduism (*q.v.*), are appealed to in a variety of ways by those theosophists who have lived after the period when knowledge of Indian religious and philosophical systems became known to thoughtful circles in Europe and the West generally. In Indian thought the *rishis* are those who have "seen" the inner wisdom and have communicated it to faithful disciples. Such communication traditionally has often been purely oral, though scriptural writings have been accepted as giving part of the divine wisdom. The distinction between esoteric wisdom, available only to the few, and exoteric wisdom, available to the masses, is often implicit in theosophical thought and practice.

There are many affinities between mysticism (*q.v.*) and theosophy. Many of the speculations in the sermons and writings of Meister Eckhart (*q.v.*) could be considered as much theosophical as mystical. Yet Eckhart is considered one of the great mystics in the Roman Catholic tradition of Christianity, though in his later years he fell under suspicion of heresy. Eckhart's doctrine asserts behind God a predicateless Godhead, which, although unknowable not only to man but also to itself, is, as it were, the essence or potentiality of all things. From it proceed, and in it

exist, the three Persons of the Trinity, conceived as stages of an external self-revealing process. The eternal generation of the Son is for Eckhart equivalent to the eternal creation of the world. But the sensuous and phenomenal, as such, so far as they seem to imply independence of God, are mere privation and nothingness; things exist only through the presence of God in them, and the goal of creation, like its outset, is the repose of the Godhead. The soul of man, which as a microcosmos epitomizes the nature of things, strives by self-abnegation or self-annihilation to attain this reunion (which Eckhart calls being "buried" in God). Regarding evil simply as privation, Eckhart does not make it the pivot of his thought as Böhme later did; but his notion of the Godhead as a dark and formless essence is a favourite thesis of theosophy.

Jakob Böhme (*q.v.*), called the theosophist par excellence, was indebted not only to mystical theology but also to the writings of Paracelsus. The nature-philosophers of the Renaissance, such as Nicholas of Cusa, Paracelsus, Geronimo Cardano, and others, curiously blend scientific ideas with speculative notions derived from scholastic theology, from Neoplatonism (*q.v.*) and even from the Cabala (*q.v.*). Hence it is customary to speak of their theories as a mixture of theosophy and physics or chemistry.

Böhme offers a natural philosophy of the same sort. His speculation turns upon the necessity of reconciling the existence and the might of evil with the existence of an all-embracing and all-powerful God, without falling into Manichaeism (*q.v.*) on the one hand, or, on the other, into a naturalistic pantheism (*q.v.*) that denies the reality of the distinction between good and evil. He faces the difficulty boldly, and the eternal conflict between the two may be said to furnish him with the ground-principle of his philosophy. It is in this connection that he insists on the necessity of the Nay to the Yea, of the negative to the positive. Eckhart's Godhead appears in Böhme as the abyss, the eternal nothing, the essenceless quiet (*Urgrund* and *Stille ohne Wesen* are two of Böhme's phrases). But, if this were all, the divine being would remain an abyss dark even to itself. In God, however, as the condition of his manifestation, lies, according to Böhme, the eternal nature or the *mysterium magnum*, which is as anger to love, as darkness to light, and, in general, as the negative to the positive. This principle (which Böhme often calls the evil in God) illuminates both sides of the antithesis, and thus contains the possibility of their real existence. By the *Qual* or torture, as it were, of this separation, the universe has qualitative existence and is knowable. Even the three Persons of the Trinity, though existing *idealiter* beforehand, attain reality only through this principle of nature in God, which is hence spoken of as their *matrix*. It forms also the matter, as it were, out of which the world is created; without the dark and fiery principle, we are told, there would be no creature. Hence God is sometimes spoken of as the father and the eternal nature as the mother of things. Creation (which is conceived as an eternal process) begins with the creation of the angels. The subsequent fall of Lucifer is explained as his surrender of himself to the principle of nature, instead of dwelling in the heart of God. He sought to place anger above love; and he had his will, becoming prince of hell, the kingdom of God's anger, which remains, however, an integral part of the divine universe.

F. W. J. von Schelling's *Philosophical Inquiries Into the Nature of Human Freedom* (1809) is almost entirely a reproduction of Böhme's ideas, and forms, along with Baader's writings, the best modern example of theosophical speculation. Emanuel Swedenborg (*q.v.*) is usually reckoned among the theosophists.

**The Theosophical Society.**—The term theosophy in later years obtained wide currency as denominating the beliefs and teachings of the Theosophical Society, founded in the United States in 1875 by Helena Petrovna Blavatsky (*q.v.*), in connection with Col. H. S. Olcott and others. Colonel Olcott remained president of the original society till his death in 1907, when he was succeeded by Annie Besant (*q.v.*). Soon after the death of Madame Blavatsky (1891) a split took place which led to the formation of a separate organization under the leadership of William Q. Judge. The parent organization, now called the Theosophical Society in America, has its headquarters at Wheaton, Ill.

The founders of the Theosophical Society assumed their con-

timidity with the ancient esoteric tradition of occultism and were ready to make the "secret doctrine" available to humanity at large. According to Madame Blavatsky's original statements, this wisdom has been transmitted through the ages as a secret doctrine by a brotherhood of adepts or mahatmas scattered through the world but in connection with one another. With a certain group of these in Tibet she claimed to be in communication. A Master Morya is supposed to have taken on Madame Blavatsky as his personal pupil, or chela. In adepts such as Morya the spiritual nature is supposed to have been so developed that the body has become the ductile instrument of the intelligence, and they have thus gained a control over natural forces which enables them to bring about results that appear to be miraculous. Many theosophists have had great interest in occult phenomena, and theosophical language includes references to astral bodies, guardian angels, and the like.

In one of her important books, *Isis Unveiled*, Madame Blavatsky seeks to establish that the one source of all the wisdom of the past is India. Christianity, according to the same volume, "copied all its rites, dogmas and ceremonies from paganism" with the exception of the doctrine of eternal damnation and the custom of pronouncing anathemas. The Indian doctrines which are often treated in theosophical writings are the identity of the human and the divine, the concept of reincarnation (see *METEMPSYCHOSIS*) and transmigration (more properly termed *samsara*), and the concept of *karma* (*q.v.*; the law of action-influence). Theosophy holds that life is a continuum, with reincarnation its evolutionary method and *karma* its determinant. *Karma* has played a prominent part in Indian thinking from the time of the late brahmanic commentaries and the Upanishads, but its operation has been interpreted in different ways. For the modern theosophist, reincarnation is the method by which the individual reaps what he has sown, and *karma* is the principle behind the method. It is used to explain the inequalities in the present life of the distribution of happiness and misery, wisdom and ignorance, and is a doctrine of hope, not of pessimism. The goal of the struggle to achieve wisdom which leads to self-actualization is Nirvana (*q.v.*), when the lower self or selves is annihilated and the true self liberated.

**THEOTOCOPULI, DOMENICO:** see GRECO, EL.

**THERA** (modern Greek THIRA; formerly SANTORIN or SANTORINI), a volcanic island in the Aegean Sea, 29 sq.mi. (75 sq.km.) in extent, one of the southernmost of the Cyclades (*q.v.*). Pop. (1961) 7,751. The eparchy of Thera, part of the Greek *nomos* (department) of the Cyclades, includes the islands of Therasia (Thirasia), Ios, Amorgos, and Anaphe (Anafi). Thera is both a Greek Orthodox and a Roman Catholic episcopal see.

In shape Thera forms a crescent, enclosing a bay on the north, east, and south; on the western side lies the smaller island of Therasia. The encircling wall thus formed, elliptical, and 18 mi. (29 km.) round its inner rim, is broken in two places: toward the northwest by a strait one mile across, where the water is not less than 1,100 ft. (335 m.) deep, and southwest by an opening about three miles wide, shallow, with Aspronisi ("white island") in the middle. From the bay, horizontally banded cliffs rise perpendicularly to as much as 1,000 ft.; but toward the open sea, both in Thera and Therasia, the ground slopes and has been converted into broad level terraces of tuffaceous agglomerate, which though bare and ashen produce the famous Thera wine. Powdered tufa is exported as cement.

Toward the southeast, the limestone peak of Mt. Profitis Ilias (1,858 ft. [566 m.]) existed before the volcano was formed. In the middle of the bay lie two small volcanic islands, Neokaimeni and Palaioikaimeni ("new" and "old burnt island"). The number and size of these islands has changed with successive eruptions of the volcano. The modern town of Thera (pop. [1961] 1,481) is built at the edge of the cliffs, overlooking the bay at a height of 900

ft. (270 m.). Other modern settlements include Emborion and Pargos inland in the south of Thera, and Oia by the northern entrance to the bay.

Most geologists agree that the whole of the bay was once covered by a single volcanic cone, represented by the outward slope of Thera and Therasia, with its crater at the Kaimeni Islands; and that the bay results from explosion and subsidence. The main eruption, which gave the island its present form, can be dated archaeologically. Beneath the layer of tufa which covers the island are remains of a town, perhaps settled from Minoan Crete, which was overwhelmed by the disaster soon after 1500 B.C. Since then Thera has been laid waste many times by eruptions and earthquakes.

In Greek legend the island of Thera originated from a clod of earth presented to the Argonauts by Triton. By the 8th century a colony from Sparta, including Minyan refugees from Lemnos, was brought by Theras, who gave the island his own name. But the chief event in Thera's history was the planting of its famous colony of Cyrene on the north coast of Africa by Battus c. 630 B.C., in accordance with a command of the Delphic oracle (see CYRENE). Thera, as a member of the League of the Cyclades, was from 308 to 145 B.C. under the protectorate of the Ptolemies.

The name Santorin (a corruption of St. Irene, patron of Thera) was known to the Arab geographer Idrisi by 1154. The Venetians occupied the island from 1207 to the Turkish conquest in 1537; for much of this time it was part of the duchy of Naxos. It declared its independence of Turkey in 1821.

The ancient capital occupied a site on the eastern coast now called Mesa Vouno, between Profitis Ilias and the sea. It was excavated in 1895–1903 by Baron Hiller von Gärtringen. There are extensive cemeteries; a heroum of Artemidoros; an agora; a royal portico; a temple of Dionysus and the Ptolemies, later dedicated to the Caesars; the Ptolemaic barracks; and a gymnasium. The main street has narrow lanes to right and left, one leading to the sanctuary of the Egyptian gods. Near the street is a small theatre, beneath the seats of which is a cistern into which rainwater drains from the auditorium; water was evidently scarce then as now. Farther southeast are the temples of Ptolemy III Euergetes and of Apollo Carneius; finally, where the rocks fall precipitously, a gymnasium of the ephebi. Several archaic *kouros* statues have been found, including some of the earliest type. Numerous rock carvings and inscriptions were also discovered. Near the west foot of Profitis Ilias is the temple of Thea Basileia, perfect even to the roof, now dedicated to St. Nicholas Marmarites.

**THERALITE**, in petrology, a group of plutonic rocks built up of basic plagioclase (labradorite), nephelite, and a titaniferous augite. The name is derived from the Greek *theran*, "to pursue," since it was believed that its discovery would complete the series of basic rocks containing nephelite as an essential constituent. They are classified in the nephelite-tephrite group in this series (see NEPHELINITE).

Olivine, an alkali-amphibole, biotite, and orthoclase may be present as subordinate constituents. With the exception of nephelite and orthoclase, the minerals of theralites are usually in well-shaped crystals. Nephelite itself may be largely represented by secondary zeolites.

Theralites are of comparatively rare occurrence. They are found in Bohemia in association with shonkinite, in Odenwald (Mt. Katzenbuckel), Ger., together with pulaskite and foyaite in the Serra de Monchique, Port., in the Kola peninsula, U.S.S.R., and among the Carboniferous intrusions of Ayrshire, Scot.

Closely related to the theralites are the teschenites (from Teschen, Czech.). In place of nephelite these rocks contain primary analcime, but types containing both nephelite and analcime are known. In central Scotland, around Edinburgh and Glasgow, teschenites are abundant, forming thick sills intrusive into the Carboniferous rocks. Teschenites are sometimes ophtic, *i.e.*, with

augite enclosing crystals of plagioclase, and show transitions to olivine-dolerite on the one hand and to picrite on the other.

The rock known as lugarite (from Lugar, Ayrshire) is a related type containing small amounts of plagioclase but abundant analcime; nephelite is present in subordinate amounts.

Other rocks related to the theralites are the essexites and shonkinites. The former are characterized by dominant plagioclase, subordinate orthoclase, and green augite, hornblende, biotite, and olivine. Nephelite also occurs commonly. By an increase in the proportion of nephelite the essexites pass into theralites. Essexites occur, together with nephelite-syenite, in Essex County, Mass., at Mt. Royal near Montreal, in southern Norway (Oslo District), at Rongstock, Czech., and among the Carboniferous teschenites of Scotland near Edinburgh and in the Campsie Fells (hills), Stirlingshire. The shonkinites are dark-coloured, igneous rocks of much rarer occurrence. Augite and orthoclase are the prime constituents, but plagioclase, barkevikite, olivine, biotite, and variable amounts of nephelite are present.

At Shonkin Sag, in the Highwood Mountains of Montana, shonkinite forms the greater part of a stratified laccolith passing at the border into a peculiar basic rock described as a leucite-basalt porphyry.

Shonkinites are also found in Ontario, British Columbia, and Indonesia (Celebes, Timor). (C. E. T.; X.)

**THERAMENES** (d. 404/403 B.C.), Athenian general and statesman who played an important part in the internal political conflicts during and after the Peloponnesian War (q.v.). He was the son of Hagnon, of the deme (township) Steiria. In the course of his controversial career Theramenes made many enemies, including the orator Lysias, while the more conservative authors of the 4th century, including Ephorus and Aristotle, tended to idealize him. Thus, it is true that Hagnon was one of the ten commissioners (*probouloi*) appointed in 413 after the disastrous Athenian defeat in Sicily to keep control over the people and their expenditure, but it is not necessary to follow Lysias when he hints that Hagnon favoured oligarchic revolution in 411. Hagnon was an old associate of Pericles (q.v.), and Xenophon is probably right to say that Hagnon's record recommended his son to the people at the start of his career. On the other hand, Ephorus certainly exaggerated Theramenes' popularity at Athens.

Nothing is known of his early career except that he was a pupil of the sophist Prodicus. He first appears in 411 as one of the leaders in the revolution of the Four Hundred. These included some extreme oligarchs, such as Antiphon, Phrynichus, and Peisander, but also many who would have been content with a moderate oligarchy, on the lines of the program published before the revolution—abolition of state pay and restriction of the franchise to those who could serve the state in person or with their money, to a maximum of 5,000. A commission of the 10 *probouloi* with 20 new members was appointed to make constitutional proposals; Cleitophon's supplementary proposal, that they should consult the old laws of the democratic founder Cleisthenes (q.v.), illustrates another line of "moderate" thought. Aristotle's *Constitution of Athens* (ch. 30) gives a "constitution for the future," ascribed to a committee of the Five Thousand, with a complicated system of four rotating councils on the Boeotian model; it contains practical proposals, some of which were later adopted, but it was certainly never effective as a whole and is probably a draft composed by a moderate at some stage of the revolution.

In the event, the commissioners, reporting to an assembly held at Colonus outside the walls of Athens (which unarmed men would not be likely to attend), only proposed the lifting of all normal constitutional safeguards. Then the oligarch Peisander pushed through a motion by which full powers were to be given to a council of 400, elected on the spot by a somewhat irregular method; they were to summon the Five Thousand only when they thought fit. The oligarchs thus took charge of the revolution that the moderates had helped make. They were soon in difficulties, mainly because of the resistance of the fleet at Samos, and had no hope except negotiation with Sparta, which proved difficult. Opposition inside Athens came to a head over the fort at Eëtionia in the Piraeus, which Theramenes and others alleged was being

built to command the entrance and admit the Spartan fleet, and a revolt began in favour of the Five Thousand. The Spartan fleet moved on to Euboea and defeated the Athenians off Eretria (September 411), after which the Four Hundred collapsed, and an enlarged Five Thousand took over as a moderate oligarchy with a franchise restricted to the hoplites (heavy infantry).

Theramenes was certainly the main leader of the opposition inside the Four Hundred, and the new constitution is usually, and no doubt correctly, regarded as his work. He did not, however, remain long in Athens but went with 20 ships first to Paros, then to Athens' friend Archelaus of Macedonia, who was besieging Pydna. Early in 410 he and Thrasybulus (q.v.) joined the main fleet in the Hellespont, where, with Alcibiades, they annihilated the Spartan fleet under Mindarus at Cyzicus. This removal of the immediate threat in the Hellespont, Athens' grain supply route, so encouraged the people that they abolished the Five Thousand and restored full democracy, leaving Theramenes and his colleagues in a somewhat anomalous position till full unity was restored with the triumphant return of Alcibiades to Athens in 407.

After Cyzicus, Theramenes was left at Chrysopolis to guard the Bosphorus and exact a toll from ships passing through it. He next appears at Arginusae in 406, not as general but as triarch in command of a ship. This Athenian victory, the last, was followed by the trial of six of the generals on the charge of not having picked up survivors from the ships disabled in the battle. They blamed the violent storm that followed the battle but also claimed that they had detailed Theramenes and Thrasybulus for this task. Xenophon alleges that Theramenes took a large part in inflaming public feeling against the generals, who were condemned to death; his apologists exonerate him. It is not easy to decide where the truth lies, though it must be said that Xenophon's account is in some ways the less coherent. Lysias says that Theramenes was elected general the following spring, but at the subsequent scrutiny he was set aside as being no friend to the people.

Late in 405, when Athens was besieged but not yet ready to surrender, Theramenes was dispatched to negotiate with the Spartan admiral Lysander. Returning three months later, when Athens was starving (his enemies said he delayed on purpose), he headed an embassy to Sparta to seek terms of capitulation, which Athens had to accept. There followed a period of political uncertainty, the democrats hoping to retain their constitution, the oligarchs and returned exiles organizing and plotting for theirs, while Theramenes and his associates probably hoped to establish something in between. Lysander eventually returned to Athens and set up the Thirty as a commission to revise the constitution. Theramenes had played a large part in their establishment, but control gradually passed to the oligarchic extremist Critias (q.v.), who was determined to retain power permanently. It is not clear what Theramenes thought of the obtaining of a Spartan garrison to support the Thirty, but later he protested against their arbitrary government and judicial murders, and to appease him a body of 3,000 was nominally admitted to citizenship. But the extremists were still afraid of his opposition, and Critias accused him of treachery before the council. His defense impressed his hearers, but Critias had him removed and forced to drink hemlock. The last drops he poured out as a libation with the words, "This to the fair Critias."

There is no reason to doubt Theramenes' patriotism or his sincere belief that a hoplite franchise was the best constitution, and this belief recommended him to later writers who disliked both radical democracy and extreme oligarchy. But there was no possibility that Athens would accept such a constitution except under violent compulsion, and Theramenes' constitutional experiments and his inability to work with the democrats weakened Athens and contributed not a little to its fall. See also **ATHENS**.

See general histories of Greece: also C. Hignett, *A History of the Athenian Constitution*, esp. ch. 10-11 (1952).

**THERAPEUTAE**, an ancient sect of Jewish ascetics believed to have lived in the vicinity of Alexandria (Egypt), near Lake Mareotis, during the 1st century A.D. They are mentioned in *De Vita Contemplativa*, attributed to the Jewish philosopher Philo, which is the sole account of the community, and they are characterized as being unusually severe in their discipline and mode of

life. See JEWISH SECTS DURING THE SECOND COMMONWEALTH: *Ascetic Sects: Therapeutae*.

**THERAPEUTICS** is the segment of medicine concerned with preventing or treating disease. Therapeutics involves the use of a wide variety of techniques, such as drugs, mechanical devices, vaccines, and psychiatry. Over the years, advocates of certain therapeutic concepts have formed themselves into groups; e.g., those of chiropractic, homeopathy, naprapathy, naturopathy, and osteopathy. In conventional modern medicine, therapeutic concepts and techniques are incorporated into such therapeutic specialties as pharmacology, immunology, preventive medicine, psychiatry, psychotherapy, and radiology. Occasionally some measure that has been discarded in the past is revived, revised, and put to medical use; more often, however, the revival serves the interest of quackery. (See separate articles on many of the subjects mentioned in this article; e.g., PHARMACOLOGY; PSYCHOTHERAPY; QUACKERY. See also MEDICINE AND SURGERY, HISTORY OF.)

**Scope.**—The scope of therapeutics is broad, as evidenced by the many types of therapy. Included are biologic therapy, which involves the use of biologic products, such as serums, vaccines, and antitoxins; chemotherapy, the use of pure chemicals to attack specific diseases; diathermic therapy, the use of diathermy equipment; shock therapy, the treatment of mental patients by passing an electrical current through the brain or by injecting insulin into the blood; endocrine therapy, the use of hormones. Other forms of therapy make use of gold, heat, high-frequency sound (ultrasound), oxygen at normal pressure or at high pressure, X-rays, radium, infrared rays, ultraviolet rays, hypnosis, water baths (hydrotherapy), anticoagulants, vitamins, aerosol mists, sea water (thalassotherapy), and surgery. Still other forms include musical therapy, physical therapy, and occupational therapy.

Practically any drug or treatment can be introduced and named as a form of therapy. Or, from another approach, practically any part of the body can be treated and the procedure called a form of therapeutics, e.g., dental therapeutics or alimentary therapeutics. Also, therapeutics may be specific or nonspecific, and it may be rational or irrational (the latter form is usually employed by quacks).

**Development.**—At the beginning of the 20th century only a few drugs and other measures were of outstanding therapeutic importance, and some of these were improperly understood. Most doctors knew the value of sun, fresh air, fresh fruit, and some pain-relieving substances, but little was known of the precise way in which they serve man. Furthermore, while surgery was a useful part of medical practice it was fraught with danger because of the lack of satisfactory antiseptic measures, satisfactory anesthetics and specific aids to combat shock, loss of blood, and infections. It is probably safe to say that modern therapeutics did not begin until after World War I although the foundation for its development was laid in earlier years by the work of Paul Ehrlich, Robert Koch, and others.

The application of measures to prevent disease and to cure those suffering from it goes back to the early history of man when someone tried to apply leaves, mud, and splints and invoked the aid of the gods. As he learned by trial and error the value of a few simple remedies he began the practice of medicine. Man had to pass to civilized ages before he found much of therapeutic value in plants, animals, and minerals, however. With the advent of modern medicine, accidental discoveries, keen observations, and careful study resulted in some useful findings. For example, the value of digitalis for heart diseases was learned by a physician in England investigating a brew made from foxglove by an elderly housewife; and the usefulness of Epsom Salts was demonstrated when a farmer became curious as to why his cattle would not drink from a certain well. Many techniques, as cupping, were tried widely and ultimately discarded. In the Western world, acupuncture generally lost favour, although it is still used in some parts of the East. Many therapeutic cults, such as pneumatism, arose and disappeared.

**Value.**—Following basic chemical and physical findings in the 19th century, modern chemotherapy and therapeutics were born.

Drugs were purified, specific measures against disease were developed, diseases were identified and techniques for diagnosis, treatment, and prevention of disease were unearthed. Some of these discoveries were based on studies seemingly unrelated to medicine. Thus, Sir Alexander Fleming found penicillin in 1928 by observing the growth of mold on bacteria-growing media in his bacteriologic laboratory, and Gerhard Domagk, while searching in 1932 for better dyes for woolen goods, found the precursor to the sulfa drugs.

Some idea of the value of modern therapeutics can be obtained by comparing statistics. During the Crimean War the French lost 8 men from diseases for every 1 killed in battle and the Russians lost 20 to 1. The common causes of death were cholera, typhus, dysentery, and infections. In the Spanish-American War 7 soldiers were lost to disease or wound infection for every 1 who died in battle. In the American Civil War 50% of the wounded died, whereas in World War I 6 to 12% died, and in World War II the death rate was 3%. In World War I the annual death rate for U.S. soldiers overseas was 12.8 for each 1,000 men abroad; in World War II it was 0.5. In World War I, 20 to 30% of soldiers who contracted pneumonia died, in World War II 1%. In 1900 a newborn child had a life expectancy of 49.2 years, but in 1940 it was 63.3 years, and in the mid-1960s it was about 68 years.

Much of this improvement was due to improvements in hygiene, health education, hospital facilities, food, sanitary measures, surgical techniques, transportation facilities, and other factors. The development of more and purer drugs, physical devices (e.g., X-ray machines), and foods for special health purposes (e.g., baby foods and foods for the sick) were important factors.

**Standardization of Therapeutic Agents.**—In most countries an attempt is made to ensure the marketing of satisfactory foods and drugs, but in only a few countries is this carried to a degree that provides assurance for user and prescriber. Many countries use pharmacopoeias as a guide for quality, but most countries do not have laws to enforce standardization of drugs or to prevent the marketing of harmful or useless substances. In the United States drugs, foods, and to some extent devices shipped in interstate commerce are subject to control in several ways: manufacturers, because of competition and fear of adverse publicity and lawsuits, try to develop effective and pure drugs and foods. In addition, the Federal Food, Drug and Cosmetic Act governs quality, labeling, and to some extent promotional claims. Acting as an agent for this and other acts is the Food and Drug Administration, which can seize and examine products and inspect factories. Another federal agency administers another federal law governing the sale of serums and vaccines. Some states and a few large cities have their own laws and agencies in this field. The medical profession is, of course, always doing its own examining and through the American Medical Association supports several councils that examine drugs, foods, and devices to determine their usefulness.

In the United Kingdom drugs are regulated by the Food and Drug Act, the Ministry of Health, and the Ministry of Agriculture, Fisheries and Food. Control of serums and vaccines, antibiotics, and certain other biological substances is set forth in the Therapeutic Substances Act. The standardization of some drugs is governed by international agreement, and an international pharmacopoeia is published by the World Health Organization.

Drugs and foods may be tested chemically, by assay on animals, and through other measures. The purer chemicals obviously pose fewer problems as a rule than do the impure mixtures, many of which are of botanical or animal origin. While most drugs can be examined by chemical tests, some (of which insulin is an outstanding example) defy such an approach. Such drugs are usually assayed by comparing new lots of the drug with an official standard preparation. The comparison is based on the drug's ability to elicit a particular biological effect under rigorously controlled conditions in a certain species of animal.

**Mode of Action.**—The selection of a method of treatment for a disease depends on several factors, such as the disease involved, the depth of illness of the patient, hazards posed by the disease as a public health menace, and the kind of remedy available. Thus a drug may be given by mouth; injected into or under the skin,

into a muscle, vein, or artery, or into other tissues of the body; or it may be applied to the skin. It may be available as a tablet, powder, or solution, or in a capsule or ointment.

A drug or other remedy may be given to specifically combat a disease; it may be given to help the body mobilize its own natural defense forces, as the sulfa drugs hold in check the growth of bacteria while the body overcomes those already present; it may be used to provide symptomatic relief, such as aspirin for headache; or it may be used to directly attack disease, such as X-rays for cancer. The choice of treatment depends on the cause of the disease, complications, and specificity of available therapeutic measures. In addition, the physician always must remember the patient's peace of mind. Sympathetic understanding of a health problem sometimes is more effective than drugs or surgery. Kind words, a change in scenery, and new friends often have effected seemingly miraculous improvement.

**Prevention of Disease.**—The prevention of disease is founded on adequate diet, adequate sanitation, and use of specific measures against diseases. Some authorities have referred to this as preventive therapeutics. School clinics, venereal disease clinics, public health laboratories, vaccination, balanced meals, extra milk for children, and addition of iodine to salt to prevent goitre, of fluoride to water to prevent dental decay, and of vitamin D to milk and vitamin C to other foods are part of current preventive practices.

Among the diseases that can be prevented by immunization are smallpox, diphtheria, yellow fever, typhoid and paratyphoid fever, measles, and poliomyelitis.

Other important preventive measures supplementary to therapy are proper disposal of sewage, eradication of disease-carrying mosquitoes, and the provision of germ-free drinking water. Since some animals and birds carry diseases to which man is susceptible, they too must be subjected to certain control measures such as testing for tuberculosis and vaccination against rabies. (See also PREVENTIVE MEDICINE.)

**Specificity of Drug Action.**—One of the encouraging aspects of modern therapeutics is the specificity of drug action. Formerly "shotgun therapy" was often the order of the day. Today, however, the physician can choose specific drugs for many diseases and health problems. Thus, one can choose the type of anesthetic agent that is best for a certain type of operation; the best type of drug for sleeplessness and pain; the type of drug best suited to muscle spasm, or high blood pressure, or allergy, or infection. Such a direct approach was made possible by the development of more precise diagnostic techniques, by a better understanding of the functions of the body, and by the combined efforts of chemists, physicians, and other specially trained people who can jointly develop first in theory and then in practice the chemicals needed to combat a certain health problem.

**THERAPSID**, a member of a major order of reptiles of the Permian and Triassic periods (about 235,000,000 to 160,000,000 years ago). Therapsids were the stock that gave rise to mammals. As early as the preceding Carboniferous Period there appeared a distinct evolutionary line beginning with the archaic mammal ancestors, order Pelycosauria, and leading toward mammals. From one pelycosaur family sprang the therapsids. Primitive therapsids are present in the Middle Permian of the U.S.S.R.; later forms are known from every continent except Australia but are commonest in the Late Permian and Early Triassic of South Africa. The limbs and limb girdles were modified for four-footed mam-

malian locomotion. The skull, as in mammals, had a single opening in the temporal region, bounded below by a bony arch. Usually the teeth were differentiated into mammallike nipping incisors, large stabbing canines, and a series of cheek teeth. The lower jaw, however, was reptilian in structure, being composed of seven bones instead of one as in mammals, and had a different, primitive articulation with the skull. In advanced forms, as in mammals, there was a bony palate in the roof of the mouth. It is possible that therapsids initiated such mammalian features as the nursing habit, development of hair, and temperature regulation.

A notable therapsid side branch was that of the herbivorous dicynodonts ("two-tuskers"), in which upper canines were generally retained but the other teeth were replaced by a horny bill. Among carnivorous therapsids, gorgonopsians and therocephalians were characteristic of the Permian and cynodonts and bauriamorphs were advanced Triassic representatives. A few therapsids were still present in the Late Triassic and even into the Jurassic, but most had by then become extinct or had evolved into a primitive mammalian stage. See also MAMMAL; REPTILE; PALEONTOLOGY.

(A. S. RR.)

**THERAVADA** ("School of Elders"), also sometimes called HINAYANA ("Little Vehicle"), is one of the two great schools of Buddhism, the other being the Mahayana ("Great Vehicle"). Theravada Buddhism holds the Pali canon of Buddhist scripture to be authoritative (see PALI LITERATURE). The school is dominant in the countries of southeast Asia—Ceylon, Burma, Thailand, Laos, and Cambodia (but not Vietnam, which is predominantly Mahayana). See BUDDHISM.

**THERÈSE, SAINT, OF LISIEUX** (MARIE FRANÇOISE THÉRÈSE MARTIN) (1873–1897), known as the Little Flower or St. Thérèse of the Child Jesus, was born on Jan. 2, 1873, at Alençon in Normandy. In the deeply religious atmosphere of her home her piety developed early and intensively, but her sister and her father spoiled her. At 15, after much opposition, she entered the Carmelite convent at Lisieux, where she kept the rule to perfection but attracted no attention. She was conspicuously a neurotic child, but at the convent, while she continued to suffer from scruples—a causeless feeling of guilt—and, at the end, from religious doubts, she was outwardly smiling and pleasant, and never exhibited any of the usual selfish manifestations of the malady. Before her death from tuberculosis on Sept. 30, 1897, she acknowledged that because of her difficult nature not one day had ever passed without a struggle. In fact she used her nervous disabilities as the very material on which she built her sanctity. She was canonized in 1925 and her feast day is Oct. 3.

Her autobiography, *Histoire d'une âme*, was first published in 1898 in an extensively rewritten and sometimes misleading form, but in 1956 a nearly genuine photostat text was produced. The best English translation is that by R. A. Knox (1958). St. Thérèse defined her doctrine of the Little Way as "the way of spiritual childhood, the way of trust and absolute surrender."

**THERMIONICS** deals with the emission of electrically charged particles from heated surfaces; these particles may be negatively charged, such as electrons, or positively charged, such as positive ions. While it was known from the 18th century that heated surfaces emit electric charges, a discovery made by Thomas A. Edison (1883) drew special attention to this phenomenon. Edison's discovery (later named the Edison effect by W. H. Preece) was that current can be made to flow between two electrodes in a vacuum if one of the two is heated. Application of this effect was made by J. A. Fleming in the construction of a thermionic rectifier or valve (diode) that allows the flow of electricity in one direction but not in the other. In 1899 J. J. Thomson established the electric charge carrier as composed of particles, each having the same charge and mass as did the electrons he had discovered about two years earlier (see also ELECTRON). In 1903 O. W. Richardson discovered the relation between the temperature of the emitting surface and the rate of emission of electrons. He also suggested the term thermionic emission for the Edison effect which

previously had been referred to as "the emission of electrons from hot bodies."

Early investigators of thermionic emission included Max von Laue, W. Schottky, and I. Langmuir. Thermionic emission of positive ions (positively charged atoms) was first observed by Richardson and was later studied by Langmuir and K. H. Kingdon (1923). They observed emission of positive ions of alkali metals adsorbed on the thermionic emitter (cathode). A second type of positive-ion emission, observed by H. B. Wahlen and L. P. Smith (1929), is that of positively charged atoms of the cathode metal itself (see *ELECTRICITY: The Particles of Electricity*).

The greatest impetus to further extension of knowledge in thermionics was the extensive practical application of devices that make use of thermionic emission. The most widely used of these are vacuum tubes used as rectifiers of alternating current and amplifiers of electric signals of low power (see *ELECTRON TUBE*). Other important applications of thermionic emission include low-voltage gas discharges (such as fluorescent lamps) and the direct conversion of heat into electric power.

**Theory of Thermionic Emission.**—Any atom includes a positively charged nucleus surrounded by one or more electrons (see *ATOM*). According to quantum theory the electrons of an atom may exist only in discrete allowed (quantum) states. The allowed electronic states of an atom may be grouped into categories called shells. In every atom with a sufficiently high atomic number (*i.e.*, number of electrons) there are two electrons very close to the nucleus that serve to fill the K shell; next is the L shell with a maximum of eight electrons. Depending on the total number of electrons associated with the atomic nucleus to make it electrically neutral, additional shells may be filled. The outermost electrons are known as the valence electrons. Almost all metals that are good conductors have only one or two of these valence electrons in the outermost shell; the details are understood in terms of wave mechanics (see *QUANTUM MECHANICS: Wave Mechanics*).

Upon crystallization the atoms of common metallic elements yield their valence electrons to quantum states of the whole crystal rather than states associated with each individual atom. These electrons are then called free electrons. The transfer of a free electron from one quantum state to another is accompanied by a change in energy of the system as a whole. At a temperature of absolute zero the most stable state of the system should tend to be that of least energy; thus the electrons should occupy low-energy quantum states, leaving those of high energy empty.

At a finite temperature the free electrons in a crystal tend to be distributed among the allowed quantum states of the crystal according to the rules of statistical thermodynamics. To a very good approximation, these rules are described by the so-called Fermi-Dirac statistics. A quantity that characterizes the condition of the free electrons in a crystal in equilibrium at a temperature  $T$  is the energy of the state that has exactly 50% probability of being occupied. This energy is called the Fermi level of the crystal, in honour of Enrico Fermi, who first developed the statistics of free electrons (see *SOLID STATE PHYSICS*).

According to Fermi-Dirac statistics, if any two electrically conducting solids are in contact and in equilibrium (neither heat nor electric current flows from one to the other) not only must their temperatures be uniform and equal but so must their Fermi level. Both temperature and Fermi level are properties called thermodynamic potentials. If two conductors have the same temperature but differ in Fermi level, this difference equals the work required per electron to move electrons from one conductor to the other. Therefore the reading of a voltmeter connected to two conductors of the same temperature equals the difference in their Fermi level, and thus the differences in Fermi level between isothermal conductors can be readily measured. Unfortunately no such simple procedure is known for measuring the absolute value of the Fermi level in a conductor.

The theory of thermionic emission is illustrated by fig. 1 in which the electron potential energy distribution in space is shown near a conductor-vacuum interface subjected to zero external electric field. The vertical direction represents energies and the horizontal represents distance. The solid line to the right of the

vertical dashed line represents the potential energy of an electron outside the last layer of atoms of a conductor crystal. Inside the conductor, the potential energy of an electron varies periodically with the atomic structure (as shown by the dotted line). The solid line to the left of the vertical dashed line represents the spatial average of this potential energy. The Fermi level  $\mu$  of the conductor is shown by the horizontal dashed line.

If the potential energy of an electron is zero at large distance away from the surface, then the potential energy inside the conductor is lower by the amount shown as  $W_a$ . This difference in potential energy is called the electron affinity of the surface. It is produced by the additive effects of the image force (the attraction of an electron by a conductor) and the forces exerted on an electron by charged dipole layers that may exist on the surface.

Fig. 1 represents what was called by Langmuir a motive diagram. A motive differs from the potential encountered in electrostatics, being the potential energy of an electron with a finite charge  $q$ , whereas the electrostatic potential is defined as the potential energy per unit of charge of an infinitesimal charge. The image force per unit of charge is finite for an electron near a conducting surface and is zero for an infinitesimal charge.

The difference between the motive (potential energy of the electrons) outside the conductor and the Fermi level is called the true work function  $\phi$  of the surface. The difference  $\xi$  between the motive inside the conductor and the Fermi level has no well-accepted name. The quantities  $\phi$  and  $\xi$  have the units of energy per electron and will be expressed in electron volts during this discussion. (Some authors define  $\phi$  as an energy per unit of charge and measure it in volts.)

The value of  $W_a$  for a particular metal (*i.e.*, crystal) depends not only on the metal but also on the particular crystallographic surface that is exposed. For example, A. R. Hutson (1955) showed that the value of  $W_a$  for the [111] surface of tungsten is less than that for the [110] surface by at least 0.8 ev (electron volts). (An electron volt is the energy gained or lost by an electron in moving across a region in which there is a difference in potential of one volt. Since the charge  $q$  on an electron is  $1.602 \times 10^{-19}$  coulomb, the electron volt is  $1.602 \times 10^{-19}$  joule.)

To help understand fig. 1, other values of the symbols will be given as they refer to tungsten. The value of  $\xi$  is about 5.8 ev. This number derives from the application of Fermi-Dirac statistics to an assembly of free electrons of concentration  $n$ , and is computed from

$$\xi = \frac{h^2}{2mq} \left( \frac{3n}{8\pi} \right)^{2/3} \left\{ 1 - \frac{\pi^2}{12} \left[ \frac{kT}{h^2 (3n/8\pi)^{2/3}} \right]^2 \right\} \quad (1)$$

In equation (1)  $h$  is Planck's constant ( $6.6256 \times 10^{-34}$  joule sec);  $m$  is the electron mass ( $9.1091 \times 10^{-31}$  kg);  $q$  is the charge on an electron;  $k$  is Boltzmann's constant ( $1.38054 \times 10^{-23}$  joule /°K or  $8.617 \times 10^{-5}$  ev/°K); and  $T$  is temperature in °K. An evaluation of  $\xi$  as it applies to tungsten (in which there are  $6.4 \times 10^{28}$  atoms per cubic metre) shows that the second term which depends on the  $T$  is so small compared to unity that  $\xi$  of 5.8 ev may be used without correction over the useful range of 1,800° to 2,500° K. Careful experimentation by M. H. Nichols (1940),

FIG. 1.—ELECTRON POTENTIAL ENERGY AT THE EMITTER REGION (MOTIVE DIAGRAM; see TEXT)

G. F. Smith (1954), and Hutson established the value of  $\phi$  as  $4.3 + (3 \times 10^{-5}) T$  for the [111] surface. It follows that  $W_a$  is close to 10.1 eV for this surface and at least 10.9 eV for the [110] surface.

Thermionic emission from a metallic conductor can be explained in terms of fig. 1. With the metal at a very low temperature, the electrons fill all the quantum states from the bottom of the motive right to the Fermi level; very few electrons will be found above this level. There will be some high-energy electrons, however, and the Fermi level will mark the quantum state that has a 50% probability of being occupied. As the temperature is raised, more and more electrons will occupy high-energy states (even as high as  $W_a$ ) and there will be vacancies in the states below  $\mu$  exactly equal to the number occupied above  $\mu$ .

In their random motion in the interior of the metal, many electrons of very high energy will approach the surface. If an electron moving at high speed has a kinetic energy associated with motion toward the boundary greater than  $W_a$ , it may escape the metal. As it crosses the boundary at the surface, however, some of its kinetic energy is transformed into potential energy.

**Richardson Equation.**—From thermodynamic considerations the current density  $J_s$  associated with the electrons that escape from a conductor is given by

$$J_s = AT^2 e^{-\phi/kT} \quad (2)$$

where  $A$  is a constant characteristic of the emitting surface,  $T$  is the absolute temperature of the surface,  $e$  is the base of natural logarithms (2.71828),  $\phi$  is the true work function of the surface, and  $k$  is Boltzmann's constant. (If  $\phi$  is expressed in eV,  $k$  must be expressed in eV/°K.) This relation was derived by Richardson in 1912; the constant  $A$  was later evaluated from the work of Von Laue (1918), S. Dushman (1922), R. H. Fowler (1928), and others to be

$$A = (1 - r) \frac{4\pi m k^2 q}{h^3} \quad (3)$$

where  $r$  is the electron reflection coefficient of the surface. For pure metals  $r$  is very small (of the order of 0.05) and is usually neglected. Then the value of  $A$  becomes

$$A = 120.4 \text{ amp/cm}^2 \text{ } ^\circ\text{K}^2$$

The value  $J_s$  in equation (2) is called the saturation current density of a surface. It equals the current extracted from the surface if, by external means, the electric field away from the surface is made equal to zero (the motive away from the surface is horizontal as in fig. 1).

Equation (2) shows that the saturation current density of a surface increases with increasing temperature and decreasing work function. The lower the work function of a surface, the higher its saturation current density at a given temperature. Thus the work function is a measure of the tendency of the conductor to retain its electrons; thermodynamically the work function of a surface equals the average work per electron required to extract electrons from a conductor and to bring them at rest outside the conductor surface.

**Emission Measurements.**—Thermionic emission may be quantitatively observed with a diode structure and an external current as shown in fig. 2. The diode structure includes a thermionic emitter and a collector separated by a vacuum gap. The emitter is heated and the collector is kept cold at a much lower temperature. When very accurate measurements are desired, a magnetic field perpendicular to the emitting surface is imposed in the system to guide the electrons from emitter to collector and minimize edge effects.

For the diode, the motive diagram corresponding to the zero-field (zero-potential-energy-gradient) condition of fig. 1 is shown as fig. 3B. The Fermi levels of the emitter and the collector are denoted by  $\mu_E$  and  $\mu_C$  respectively, and the corresponding work functions of these electrodes by  $\phi_E$  and  $\phi_C$ . The motive diagram of fig. 3B is laterally compressed (about 10,000 times) as compared to that of fig. 1 because the change in the potential energy

FIG. 2.—ARRANGEMENT FOR MEASURING DIODE CHARACTERISTICS

$I$  is observed current;  $V$  is applied voltage

across a surface (shown in detail in fig. 1) occurs over a distance of the order of  $10^{-8}$  cm whereas the distance between emitter and collector of a diode is of the order of  $10^{-1}$  cm.

The voltage  $V$  applied to the diode multiplied by the electronic charge  $q$  equals the difference in Fermi levels ( $\mu_E - \mu_C$ ) of the electrodes. For the condition illustrated in fig. 3B, the current flowing through the diode equals the saturation current  $I_s$  of the emitter ( $J_s$  times the emitter

area). If the voltage applied to the diode is increased significantly above the value  $V_b$  of fig. 3B, an electron-accelerating electric field (potential energy gradient) will exist near the emitter surface and the current flowing through the diode will increase beyond the saturation current of the emitter (fig. 3A). This phenomenon, called the Schottky effect, was first pointed out by Schottky in 1914; in the presence of an electron-accelerating field  $E$ , the current flowing through the diode is given by the Schottky equation

$$I = I_s e^{\frac{q^2}{4\pi\epsilon_0} \frac{q}{kT} (E)^{1/2}} \quad (4)$$

where  $\epsilon_0$  is the permittivity of free space ( $8.854 \times 10^{-12}$  farad/m) and  $E$  is the electric field near the emitter surface. For parallel-plate geometry and large values of the applied voltage  $V$ ,  $E$  approximately equals  $V$  divided by the interelectrode distance.

If  $V$  is decreased below  $V_b$ , the motive diagram will have a maximum value  $\psi_m$  greater than the electron potential energy  $\psi_E$  near the emitter surface, as shown in fig. 3C. The shape of the motive diagram in fig. 3C arises from the negative charge of the electrons in transit from emitter to collector. The current flowing through the diode under these conditions will be less than the saturation current. Of the electrons in the emitter that move toward the surface only those with kinetic energies greater than  $\psi_m$  will reach the collector; all others will be reflected back into the emitter. This phenomenon is called space-charge effect and was analyzed by Langmuir (1923) who gave an exact solution for the current flowing through a planar diode under space-charge conditions.

The location of the motive maximum under space-charge conditions depends on the applied voltage  $V$ . For sufficiently low values of  $V$ , usually negative, the motive maximum reaches the collector surface. This condition of operation is called the critical point. For values of  $V$  less than that corresponding to the critical point, no maximum appears in the interelectrode space (fig. 3D). Under this condition the diode is said to operate in the Boltzmann mode.

FIG. 3.—MOTIVE DIAGRAMS FOR VACUUM-DIODE OPERATION IN: (A) SCHOTTKY MODE; (B) SATURATION MODE; (C) SPACE-CHARGE MODE; (D) BOLTZMANN MODE

$\phi_E$  is emitter work function;  $\phi_C$  is collector work function;  $\mu_E$  is emitter Fermi level;  $\mu_C$  is collector Fermi level;  $V_a$ ,  $V_b$ ,  $V_c$ ,  $V_d$  are applied voltages;  $q$  is electronic charge

The current flowing through a diode operating in the Boltzmann mode is limited only by the value of the electron potential energy  $\phi_0$  near the collector surface.

Thus, depending on the value of the applied potential, a thermionic diode may operate in the Schottky mode, the saturation mode, the space-charge mode, or the Boltzmann mode. For each of these there is a prescribed relation involving the current, the applied voltage, and other parameters such as emitter temperature, emitter work function, and interelectrode distance. A typical complete current-voltage ( $I$ - $V$ ) curve of a thermionic diode is plotted as fig. 4 in semilogarithmic scale. The various modes of operation are indicated in the figure.

An important part of the  $I$ - $V$  curve of fig. 4 is that corresponding to the Boltzmann mode. Here the curve is the straight Boltzmann line, indicating that the current changes exponentially with applied voltage. This results from the nature of the energy distribution of the electrons in the emitter and may be deduced theoretically; it can be shown that the slope of the Boltzmann line is proportional to the inverse of the absolute temperature of the emitter.

Another important part of the  $I$ - $V$  curve is the saturation line; this specifies the emitter saturation current, which (with the Richardson equation) may be used to evaluate the true emitter work function.

**Empirical Equation and Thermionic Constants.**—Equation (2) is often experimentally validated by observing saturation current density  $J_s$  as a function of temperature  $T$  and plotting the data according to

$$\ln \frac{J_s}{T^2} = \ln A_R - \frac{\phi_R}{kT} \quad (5)$$

where  $A_R$  is the empirical Richardson constant and  $\phi_R$  is the

FIG. 4.—TYPICAL VOLTAGE-CURRENT CURVE FOR A VACUUM DIODE

The logarithm of the current ( $I$ ) flowing through a diode versus voltage ( $V$ ) applied to the diode terminals.  $I_s$  is the saturation current of the emitter

Richardson work function as an empirical constant. The observable quantity on the left of equation (5) is plotted as a function of  $T^{-1}$  or, better yet, as a function of  $1/kT$ . Generally a straight-line relation is found and values of  $A_R$  and  $\phi_R$  are determined this way.

Comparisons are often made between  $A_R$  and the theoretical value of the universal constant  $A$  of equation (2). More often than not  $A_R$  is less than  $A$ , but many examples are found in which  $A_R$  is much greater than  $A$ . One reason for these differences is that a given sample generally does not exhibit a single crystallographic surface for emission; therefore, the observed  $J_s$  is an average of  $J_s$  for many crystals. It will be less than the maximum saturation density and greater than the minimum of the various exposed surfaces of a test sample.

Another reason is that nothing in the theory from which equation (2) was obtained limits its use to the condition that  $\phi$  is a constant. In fact, equation (5) will be satisfied if  $\phi$  changes linearly with temperature according to the relation

$$\phi = \phi_R + \alpha kT \quad (6)$$

where  $\alpha$  is the temperature coefficient. It may be seen that the observed value of the constant  $A_R$  would be altered by the factor  $e^{-\alpha}$  from the theoretical  $A$ . Thus if  $\alpha$  is negative, as it may be when adsorbed electronegative atoms are present as surface impurities,  $A_R$  can be very large; if  $\alpha$  is positive  $A_R$  will be small.

Experimental values of  $A_R$  and  $\phi_R$  have very little theoretical importance, even though they have use in engineering. These numbers may be used to predict the electron emission that will be available from similar samples, but  $\phi_R$  will very seldom be the true work function  $\phi$  defined in fig. 1. The basic Richardson thermionic relationship is equation (3), and there the work function  $\phi$  is the only one to use. The empirical values of the thermionic constants  $A_R$  and  $\phi_R$  are referred to as the Richardson constants. They are to be used with the form of the equation given by

$$J_s = A_R T^2 e^{-\frac{\phi_R}{kT}} \quad (7)$$

Values of thermionic constants for various elements and compounds are given in the table.

**Oxide-Coated Cathodes.**—Widespread application of thermionic emission to electronics largely rests on the low-work-function oxide cathode. This development was initiated with the discovery by A. Wehnelt (1903) that a coating of alkaline-earth oxides (CaO, SrO, and BaO) greatly enhances electron emission from a metallic surface. The oxide cathode generally consists of a nickel substrate upon which a suitably prepared barium-strontium carbonate is sprayed. The fine particles are held in a binder, which is later removed by heating. The conversion of the carbonate to the oxide takes place within the final assembly during the early stages of evacuation. The conversion is completed by maintaining the cathode at about 1,300° K for about one minute (G. M. Herrmann and J. S. Wager, 1951).

Important factors that govern the procedure include: the need for nickel alloys that contain reducing agents such as silicon, titanium, and magnesium (E. S. Rittner, 1953); development of required particle size of about two or three microns; porosity after sintering of about 50% with pores of about two microns in linear dimensions; cleaning of all other parts of the tube, which is important for maintenance of cathode emission life; and coating adherence which is dependent on such factors as vacuum conditions and cleaning of parts.

Thermionic Constants\*

Element	$A_R$	$\phi_R$	$J_s$	$T$
Carbon . . . . .	30	4.34	$1.4 \times 10^{-8}$	2,000

\* $A_R$  is the Richardson constant in amp/cm<sup>2</sup> °K<sup>2</sup>;  $\phi_R$  is the Richardson work function in eV;  $J_s$  is the saturation current density in amp/cm<sup>2</sup>;  $T$  is the emitter temperature in °K.

Electron emission from this structure depends on transfer of electrons from the nickel base metal to the coating, conduction through the coating, and finally emission from the coating. Barium oxide in the absence of imperfections is a very poor conductor of electrons. However, the presence of an amount of excess barium in the oxide of 1 to 20 parts per 1,000,000 is enough to raise the conductivity of the coating to tolerable levels.

The work function of an oxide-coated cathode depends on the composition of the coating and on the treatment used to activate

it. For most types of cathode, the Richardson work functions are within about 0.3 ev of 1.1 ev for BaO and 0.3 ev of 1.4 ev for SrO.

During the life of a cathode, barium is evaporated; it also may be lost effectively if electronegative gas such as oxygen is evolved from other parts of the tube and goes to the cathode. The reducing agent in the nickel alloy acts to maintain the required concentration of barium to compensate for these losses. Migration of excess barium atoms is influenced by the concentration gradient and by internal electric fields. Since the flow of electrons through the coating produces a drop in potential across the coating (which is positive near the exterior surface and negative at the nickel), excess barium ions in the crystals tend to flow away from the surface. This flow reduces the concentration there and increases the resistance.

The life of an oxide-coated cathode decreases rapidly with increasing operating temperature because of evaporation of the oxides. On the other hand, saturation emission density of the cathode increases with temperature as indicated by the Richardson equation. It follows that the life of the cathode decreases with increasing saturation emission. Typical cathodes operated at saturation current densities of 0.1 to 1 amp/cm<sup>2</sup> last for a few thousand hours.

In the L cathode (developed by the Phillips Laboratories in the Netherlands) the oxides are impregnated into the supporting metal, mostly porous tungsten, rather than coated on it. This cathode has an oxide evaporation rate that is significantly less than that in coated cathodes and may be operated at a higher temperature for a given life. Typical operation of L cathode is 8 amp/cm<sup>2</sup> for about 10,000 hours.

**Cathodes with Adsorbed Monatomic Layers.**—Langmuir and W. Rogers (1913) discovered that thorium (ThO<sub>2</sub>) occluded within a tungsten wire at the time of manufacture could be made to yield thorium by suitable heat treatment. The thorium atoms diffuse out of particularly active regions along crystal boundaries and finally over the external surface of the tungsten wire to form a cover that averages less than one atom thick. The thorium adheres very strongly to the underlying tungsten surface and becomes polarized. The direction of the dipole corresponds to a displacement of the outermost valence electrons of the thorium toward the tungsten. This displacement or polarization of the negative charge with respect to the positive charge on the thorium nucleus creates a dipole moment at each thorium atom (see DIPOLE MOMENTS).

A dipole layer formed on a metallic surface reduces the work function of the surface by an amount proportional to the dipole moment per unit of area. The dipole moment per unit of cathode area of an adsorbed film depends on the surface fraction  $\theta$  that is covered by adsorbed film. For thorium on tungsten the maximum dipole moment occurs when  $\theta$  equals 0.7; the corresponding reduction of the work function of tungsten at this point is about 2.9 ev from 4.6 ev to 1.7 ev.

For a thoriated tungsten cathode operating at a given temperature, the coverage  $\theta$  will assume a value corresponding to an equilibrium between the rate of diffusion of thorium atoms to the surface and the rate of evaporation at the surface. If  $\theta$  is varied by externally controlled means, the work function of a metallic surface at any given temperature can be set at any value (within limits). This very desirable situation obtains when refractory metal cathodes are operated in an atmosphere of alkali-metal vapour.

Langmuir and Kingdon (1923) observed that a tungsten filament immersed in cesium vapour exhibits very high emissions at relatively low temperatures. This phenomenon was studied in detail by J. B. Taylor and Langmuir (1933) who gave detailed experimental data as well as a theoretical analysis for the electron emissions of tungsten in the presence of cesium vapour. They found that cesium adsorbs on the surface of the tungsten at a value of  $\theta$  that depends on the temperature of the tungsten and on the pressure of the vapour. For any given temperature of the tungsten, the coverage  $\theta$  of the adsorbed cesium layer may be varied from 0 to 1 by varying the pressure of the vapour. In this manner the work function of a cesiated-tungsten surface may be varied from

4.6 ev (corresponding to pure tungsten) to 1.69 ev (corresponding to  $\theta$  equal to 0.67). Similar behaviour was later observed for all investigated combinations of refractory metals with alkali-metal vapours.

Fig. 5 shows the saturation current density of cesiated tungsten as a function of emitter temperature  $T$ . The solid S-shaped lines are based on the theory of Taylor and Langmuir; each corresponds to a given cesium pressure  $P_{cs}$ . Each slanted straight line corresponds to a given work function of the composite surface. These lines were verified experimentally by J. M. Houston (1961), who extended the measurements of Taylor and Langmuir to higher cesium pressures. In the experiments, the cesium pressure  $P_{cs}$  near the cathode is fixed by fixing the temperature  $T_{cs}$  of a reservoir containing saturated liquid cesium and letting the reservoir communicate with the cathode enclosure. Fig. 6 shows a compilation of emission measurements by G. N. Hatsopoulos and A. Shavit (1965) for rhenium in cesium vapour.

In addition to their ability to attain a wide variety of work functions, alkali-metal-coated cathodes have practically limitless lives. Oxide-coated cathodes or thoriated-tungsten cathodes are depleted of their coating by evaporation, but the coating of alkali-metal surfaces is continuously regenerated by condensation from the vapour phase. In spite of these remarkable advantages, however, such cathodes were rarely used (the alkali-metal vapour interferes with the normal operation of most electron tubes) until they were found to be applicable in thermionic converters developed after 1958.

**Ion Emission from Alkali-Metal-Coated Cathodes.**—Alkali-metal cathodes emit positive ions as well as electrons. The rate of ion emission is proportional to the rate of atom arrival from the vapour to the surface and to a factor  $f$  given by the Saha-Langmuir equation

$$f = \frac{1}{1 + 2e^{(V_1 - \phi)/kT}}$$

where  $V_1$  is the ionization potential energy of the vapour atoms and  $\phi$  and  $T$  refer to the surface.

It can be seen from this equation that (for given atom arrival rate and surface temperature) the ion emission rate increases with increasing work function of the surface; by the Richardson equation the electron emission rate decreases with increasing work function. For given  $\phi$ ,  $T$ , and atom arrival rate, the ion emission from a surface increases with decreasing  $V_1$ . Since cesium is the

FIG. 6.—THERMIONIC EMISSION FROM A RHENIUM SURFACE IN CESIUM VAPOUR

Each dashed curve corresponds to a fixed saturation current density in amp/cm<sup>2</sup>; each dash-dot curve corresponds to a fixed positive-ion emission current in amp/cm<sup>2</sup>; each solid line corresponds to a fixed emitter work function in eV; the dotted line corresponds to equal and opposite charge densities for the emitted electrons and the emitted ions

element that has the lowest ionization potential  $V_i$  (3.87 eV), it is clearly the best-suited material for producing ions at a surface.

**Thermionic Conversion.**—The diode voltage-current curve of fig. 4 shows that current flows from the emitter to the collector not only when a positive voltage  $V$  is applied to the diode terminals but also when  $V$  is negative. When both  $I$  and  $V$  are positive, the diode absorbs electric power from the external circuit. When  $I$  is positive and  $V$  is negative, however, the diode delivers electric power to the external circuit (as does a discharging electrolytic cell). Thus the diode becomes a generator of electricity and is called a thermionic energy converter. The electric energy is produced by heating the emitter; this gives the electrons in the emitter much more kinetic energy than the electrons in the collector. More electrons may flow from emitter to collector than from collector to emitter even when the collector is maintained at a higher Fermi level than that of the emitter. Thus a thermionic converter directly converts heat energy into electrical work without mechanical moving parts.

In the thermodynamic sense (see THERMODYNAMICS) a thermionic converter is a heat engine in that it receives heat energy at a high temperature (emitter), rejects a smaller amount of heat energy at a low temperature (collector), and produces electrical work. Its efficiency is, therefore, limited by the Carnot efficiency:

$$\eta \leq \frac{T_E - T_C}{T_C}$$

where  $\eta$  is the thermal efficiency (work out divided by heat energy in) of the thermionic converter.  $T_E$  is the emitter temperature, and  $T_C$  is the collector temperature. The current that flows through a thermionic converter depends on the output voltage  $V$ , the temperatures  $T_E$  and  $T_C$ , and the work functions  $\phi_E$  and  $\phi_C$  of the electrodes, and on the characteristics of the space between emitter and collector through which electrons flow. The output

power delivered by a thermionic converter equals the current times the output voltage corresponding to that current. If no current is drawn from a diode (open circuit) the voltage difference between the electrodes adjusts so that an equal number of electrons flow in both directions. The open-circuit output voltage of a thermionic converter depends, therefore, both on its emitter and its collector temperatures.

Many types of thermionic converter have been investigated since 1955; the simplest are vacuum-diode converters first demonstrated by Hatsopoulos and J. Kaye (1957) and improved cesium-cathode diode converters first demonstrated by V. Wilson (1957). In vacuum-diode converters, emitter and collector are separated by an evacuated space; maximum output current is much lower than the saturation current of the emitter because of space-charge effects. To minimize these effects vacuum-diode converters have been built with very small interelectrode spacings (of the order of 0.001 cm). Cesium-cathode diode converters have refractory metal emitters and collectors separated by cesium vapour; space-charge effects are minimized or eliminated by positive cesium ions that are thermionically emitted or produced in the interelectrode space. Because of such advantages most thermionic converters built after 1962 were of this type.

Thermionic converters operate at high temperature (typical emitter-temperature operating range 1,600°–2,000° K), high power density (5–50 watts/cm<sup>2</sup>), and moderate efficiency (10–20%). They may be used with a variety of heat sources (nuclear reactors, decaying isotopes, sunlight concentrated with parabolic mirrors, and burners using hydrocarbon fuels). Their principal applications are for space vehicles and military power supplies where weight and unattended operation are at a premium (see ENERGY CONVERSION, DIRECT).

**THERMITE**, a mixture of aluminum powder and iron oxide used in welding, in foundry work as a source of heat, and in the reduction of metal oxides. Thermit, a trade name, often is used in the metallurgical industry both for the mixture and the process. Thermite was widely used in incendiary bombs in the European theatre during World War II.

On ignition the reaction  $(8\text{Al} + 3\text{Fe}_2\text{O}_3 = 9\text{Fe} + 4\text{Al}_2\text{O}_3)$  gives a temperature estimated to be about 2,400° C. The reaction, stated in weight, means that 216 parts of aluminum plus 695 parts magnetite (iron oxide) equals 503 parts iron plus 408 parts slag, or approximately three parts of aluminum plus ten parts of magnetite will produce, on combustion, seven parts of iron. The iron thus produced represents about one-half the original thermite by weight and about one-third by volume.

Although the above reaction is the one commonly termed the thermite reaction, a generalized thermite reaction may be defined as an exothermic, self-propagating process in which finely divided aluminum powder is used to reduce metal oxides; the metal is liberated by direct oxidation of aluminum to aluminum oxide, with accompanying reduction of the less stable metal oxide.

Thermite was discovered by Hans Goldschmidt of Essen, Ger., in 1895, while trying to reduce chromium and manganese oxides. Goldschmidt's principal discovery related to a simple and safe method of ignition, as the action of aluminum when mixed with various oxides, sulfides and chlorides was well known. Fine aluminum powder will not react with pure iron oxide below a temperature of about 1,100° C. Previous experimenters had resorted to heating mixtures in a crucible, making the initial temperature so high that at the moment of ignition the mixture reacted with explosive violence. Goldschmidt obtained ignition of a cold mixture by using a barium-peroxide fuse. Later, magnesium powder or ribbon was used to ignite the thermite. The reaction, once initiated locally in a cold mixture, then spreads through the mixture since the heat generated by the reaction will ignite adjacent regions. Goldschmidt's original U.S. patent was granted March 16,

1897, and related principally to the use of aluminum as a reducing agent for the production of carbon-free metals such as cobalt, chromium, magnesium, tungsten, etc., by what is known as an aluminothermic process.

**Uses.**—The thermite reaction is of importance for its use as a heat and metal source in welding, as a heat source in foundry work to supply heat to one region of a mold, and as a source of carbon-free metal. Two methods of thermite welding are used. The first method, known as the plastic method, can be used for welding pipe. In this method, the thermite is simply used as a heat source. The ends of two pieces of pipe are carefully butted together, and after being heated to forging temperature by the thermite, are forced together, completing the weld. The second method, known as the fusion method, is used to weld large metal sections, such as ship rudder frames. Here the molten iron formed by the thermite is used to join two or more large metal members. (For a detailed description of thermite fusion welding, see *WELDING: Aluminothermic Welding*.) Thermite welding does not compare favorably with other methods of welding and is consequently relegated to special cases such as welding very large sections and welding in areas to which equipment cannot be easily transported. The thermite reaction is used in foundry work to provide heat to the metal reservoir called the riser. Since the riser is the last to freeze, it is consequently able to feed metal to the casting as solidification proceeds. The thermite reaction is used for the manufacture of carbon-free metals either by direct ignition in a separate magnesia-lined steel crucible or by reaction in a ladle of molten metal to which the carbon-free metal is to be added. Since it is difficult to control the reaction so that it proceeds stoichiometrically, the resultant carbon-free metal usually contains small quantities of aluminum.

One of the greatest hazards in the thermite reaction results from contamination with moisture. During the reaction water is reduced and hydrogen evolved, which can produce an explosive mixture with the surrounding air. This hazard necessitates careful packaging and handling to exclude moisture from the mixture. (J. Wu.)

**THERMOCHEMISTRY** deals with the changes in heat that take place during chemical reactions. Information about the magnitude of these changes is important to the chemical engineer, who must provide for the addition of the amount of heat needed or the removal of the amount of heat generated in proposed chemical reactions. Furthermore, with the accumulation of thermal data on a sufficient number of related reactions the driving force of any proposed reaction may be calculated. Calculations of this nature are of great economic importance. For example, if calculations show that under no conditions will a particular reaction proceed, then it is a complete waste of time and money to attempt it. (In the past much effort has been wasted in attempting to obtain reactions that calculations later showed were impossible.) Thermal calculations upon reversible reactions in equilibrium enable the chemist to predict the concentration of a desired product under a given set of conditions and also to predict changes in the concentration that will be obtained when conditions are altered. Quantitative information of this kind from thermochemistry, coupled with information about the rates of reactions (the domain of reaction kinetics; *q.v.*), provides the guidelines for modern laboratory procedures in chemical science.

Thermal change accompanying a chemical reaction is itself not a measure of the driving force of the reaction. Instead, the change in a property called the Gibbs energy (see below, *Entropy and Gibbs Energy*) is the true measure of the driving force. Thermochemistry gained its first impetus in the middle of the 19th century, however, when P. E. M. Berthelot of Paris and Julius Thomsen of Copenhagen (*q.v.*) independently advanced the theory (later shown to be erroneous) that the heat content of a compound was the true measure of its chemical "affinity"—the term then used to describe energies which drive chemical reactions. The investigator mainly responsible for clarifying thermal relationships in chemical reactions was the U.S. mathematical physicist J. Willard Gibbs (*q.v.*), whose work during the last quarter of the 19th century placed thermochemistry on a firm theoretical footing.

Thermochemistry is to a large extent an experimental science involving measurements of the heats of various reactions. A unit of heat often used is the calorie (*q.v.*), and an apparatus for measuring heat quantities is called a calorimeter. Calorimetry is therefore the practical basis of experimental thermochemistry. For a detailed discussion of calorimetric apparatus and methods see *CALORIMETRY*.

This article consists chiefly of illustrations of the work of the thermochemist; the principles that guide him are presented in fairly elementary form and in a sequence intended to explain laboratory operations. For a detailed discussion of the thermodynamic laws and mathematical operations upon which thermochemistry is based, see *THERMODYNAMICS*.

## PROPERTIES AND THEIR MEASUREMENT

### Measurement of Energy Changes at Constant Volume.—

The first law of thermodynamics states that it is impossible to create or destroy energy. The total energy of a substance or system is therefore a single-valued function of its state and is independent of the path by which that state was reached. If this were not so, energy could be created by devising a suitable cycle in which a certain state is reached by one path and the system is returned to the starting state by another path.

Unfortunately it is impossible to measure or to know the total energy of a system. Therefore measurements are limited to the changes in energy of a system. The total energy, often called the internal energy, of a system is designated by  $E$  and changes in energy by  $\Delta E$ . A mathematical statement of the first law of thermodynamics is that in any process

$$\Delta E = Q - W \quad (1)$$

where  $Q$  is the heat absorbed by the system and  $W$  is the work done by the system on its surroundings (heat and work being different forms of energy).

If a process is carried out under conditions in which no work is done ( $W = 0$ ), then the measured heat absorbed is the change in total energy of the system. In many chemical reactions the only work done by the system is mechanical work of expansion against the surrounding atmosphere. Therefore, if a reaction of this type is carried out in a constant-volume container, *i.e.*, one in which no expansion or contraction is possible, no work is done and the measured heat absorbed is the change in total energy for the reaction. This is expressed by

$$\Delta E = Q_v \quad (2)$$

In equation (2), as in other thermodynamic equations, subscript  $v$  is used to denote that the quantity or operation it qualifies is limited to the condition of constant volume. (Similarly, subscript  $p$  denotes the condition of constant pressure.) Measurements of heat absorbed or evolved at constant volume are an important and typical concern of thermochemistry. It is mathematically obvious that if heat is evolved during the experiment,  $Q_v$  will be a negative number. In this case the total energy of the system is decreased by the amount of energy (heat) evolved.

Typical of reactions for which the total energy change is measured by measuring the heat evolved at constant volume are combustions of organic materials in oxygen in a bomb calorimeter. An example is the determination of the heat evolved when gasoline is burned in oxygen. There are many gasoline mixtures and the heat evolved by each is important in the assessment of the commercial value of the mixture. A sample of a gasoline is placed in a heavy reaction vessel, called a bomb. The bomb is pressurized with oxygen and submerged in a known amount of water in a calorimeter. When the gasoline is ignited the heat evolved is transferred to the water and the temperature rise of the water is measured. If the calorimeter has been calibrated with a known amount of heat, the temperature rise of the water is a measure of the heat evolved in the reaction. The total energy change in the combustion of gasoline is thus measured in an experiment in which no work is done, even though the usual use of the reaction is to produce work by moving a piston in a gasoline engine.

The above is an example of the direct practical use of a thermo-

chemical method. However, a much more important use of thermochemical methods is for the determination of total energy changes in fundamental reactions. These determinations lead to basic thermochemical data that can be tabulated and used to calculate energy changes in further reactions (see below, *Tables and Calculations*).

#### Measurement of Enthalpy Changes at Constant Pressure.

Measurements of the heats of reaction evolved at constant pressure are also of interest. Many chemical reactions are carried out in open vessels at the constant pressure of the atmosphere surrounding them. In practical situations, therefore, knowledge of the heat of the reaction allows the engineer to provide for the removal or addition of this heat in the design of a plant for carrying out the reaction. More fundamentally, the heat of reaction at constant pressure is of interest because it is a basic thermodynamic property.

To explore the meaning of the heat of reaction at constant pressure, it is necessary to relate work to pressure and volume. Consider a reaction carried out in a cylinder, one end of which is closed and the other end of which is a piston held in place only by the pressure of the air outside. In this case the work done is only that of moving the piston against air pressure. The mechanical work done,  $W$ , is equal to the force,  $f$ , exerted on the piston multiplied by the distance,  $s$ , the piston is moved during the reaction; that is,

$$W = fs \quad (3)$$

The pressure,  $P$ , of the air is the force exerted per unit area,  $A$ , of the piston; that is,

$$P = f/A \quad (4)$$

Rearranging equation (4) gives

$$f = PA \quad (5)$$

and substitution of equation (5) in equation (3) gives

$$W = PA_s \quad (6)$$

But the area of the piston times the distance it moves is the volume change,  $\Delta V$ , of the reaction. Therefore at constant pressure it is found that

$$W = P\Delta V \quad (7)$$

Substitution of  $P\Delta V$  for  $W$  in equation (1) and the use of  $Q_p$  to indicate that the heat absorbed was measured at constant pressure gives

$$\Delta E = Q_p - P\Delta V \quad (8)$$

or

$$Q_p = \Delta E + P\Delta V \quad (9)$$

Because of the usefulness of  $Q_p$  a thermodynamic property,  $H$ , is defined as

$$H = E + PV \quad (10)$$

$H$  is called the enthalpy, or heat content, of the system. Because  $E$  and  $PV$  are single-valued functions of the state of the system, it is apparent that  $H$  must also be a single-valued function of the state of the system. For a constant pressure reaction, then, when there is no work done other than  $PV$  work, the enthalpy change is

$$\Delta H = Q_p = \Delta E + P\Delta V \quad (11)$$

For calculations of  $\Delta V$  for equation (11) the volumes of liquids and solids are generally negligible compared to the volume of the gases and it is necessary to consider only the gaseous volume change. It is also sufficiently exact to consider that the gases in the reaction obey the perfect gas law,

$$PV = nRT \quad (12)$$

where  $n$  is the number of moles of gas,  $R$  is the gas constant, and  $T$  is the absolute temperature. Therefore

$$\Delta H = \Delta E + (\Delta n)RT \quad (13)$$

where  $\Delta n$  is the change in number of moles of gas only. Equation (13) is the relation between  $\Delta E$  and  $\Delta H$  usually used for obtaining  $\Delta H$  values from  $\Delta E$  determinations.

Typical of reactions for which heats of reaction at constant pressure are measured directly are combustions of one gas in another gas. For example, hydrogen and oxygen at atmospheric pressure are ignited in an appropriate torch burner in a reaction vessel submerged in the water of a calorimeter. The heat evolved is transferred to the water and the temperature rise is measured. The amount of reaction that occurred in the experiment is determined by the amount of water formed by the combination of hydrogen and oxygen. The measured heat is  $Q_p = \Delta H$  for the reaction.

It has now been shown that  $\Delta E$  and  $\Delta H$  for various reactions may be measured. It also has been shown that  $\Delta E$  and  $\Delta H$  are related by the simple relation of equation (13), so that it is only necessary to measure either  $\Delta E$  or  $\Delta H$  to know  $\Delta H$ . Direct measurements of  $\Delta E$  and  $\Delta H$  for various reactions comprise the bulk of experimental thermochemistry.

**Heat Capacities.**—The properties  $E$  and  $H$  are functions of temperature. Therefore, to calculate  $\Delta E$  and  $\Delta H$  values for temperatures other than those under which the measurements are made, a knowledge of the variation of  $E$  and  $H$  with temperature is necessary. These variations are called heat capacities and are designated  $C_v$  and  $C_p$  respectively.

When a substance is subjected to a known amount of heat,  $Q$ , over a temperature span from  $T_1$  to  $T_2$ , the temperature rise is  $T_2 - T_1$ . This physical change is treated like any other reaction. If the heating is carried out at constant volume no work is done ( $W = 0$ ), so  $\Delta E = Q_v$ . The variation of  $E$  with temperature is then

$$\Delta E/\Delta T = Q_v/(T_2 - T_1) \quad (14)$$

It should be emphasized that heat capacities themselves vary with temperature. However, if the temperature rise is small (of the order of a few degrees) it is sufficiently exact to say

$$\Delta E/\Delta T = Q_v/(T_2 - T_1) = C_v \quad (15)$$

where  $C_v$  is the average heat capacity at constant volume for the temperature range  $T_1$  to  $T_2$ , or  $C_v$  is the heat capacity at constant volume for the temperature  $(T_1 + T_2)/2$ .

For some experiments a sample of a substance heated to a high temperature,  $T_2$ , in a constant-volume capsule is dropped into a calorimeter at a much lower temperature,  $T_1$ , and the heat given off is measured. For these measurements

$$\Delta E = Q_v = E_{T_1} - E_{T_2} \quad (16)$$

where  $E_{T_1} - E_{T_2}$  is the difference in total energies going from  $T_2$  to  $T_1$ . Because heat is given off,  $Q_v$  will be negative. For changes involving large temperature differences the application of equation (15) will not yield accurate heat capacity data; for some purposes, however, the equation is useful. The heat capacity thus obtained is called the integral heat capacity for the range of temperature involved. Experiments like these are best used to measure directly the energy differences between two temperatures rather than to obtain heat capacities.

Similar experiments may be carried out at constant pressure. Then, because  $\Delta H = Q_p$ ,

$$\Delta H/\Delta T = Q_p/(T_2 - T_1) = C_p \quad (17)$$

for small temperature ranges, and

$$\Delta H = Q_p = H_{T_2} - H_{T_1} \quad (18)$$

for the drop experiment. Thermodynamic tables usually provide values for both  $C_p$  and  $H_{T_2} - H_{T_1}$ .

**Heats of State; Changes.**—The properties  $E$  and  $H$  are also functions of the physical state of the substances studied. Therefore, to calculate  $\Delta E$  and  $\Delta H$  values for reactions in which the reactants or products are in states other than those for which the studies were made, a knowledge of the variation of  $E$  and  $H$  with state is necessary. Typical of such measurements is that of the heat of vaporization of water. If the heat absorbed in changing

water from the liquid to the gaseous state at constant pressure is measured, then

$$\Delta H = Q_p = \Delta H_{vap} \quad (19)$$

in which equation  $Q_p$  is the measured heat and  $\Delta H_{vap}$  is the heat of vaporization of water.

Heats of transition from one crystalline state to another are usually designated  $\Delta H_{tr}$  and heats of fusion, from the solid to the liquid state, as  $\Delta H_{fus}$ . These heat values are also found in thermodynamic tables.

**Entropy and Gibbs Energy.**—For the chemist, the principal value of thermodynamics is its ability to establish criteria for the feasibility or spontaneity of a proposed chemical reaction under specified conditions. As was mentioned in the introduction, at one time it was believed that the sign of  $\Delta H$  for a reaction was a sufficient criterion of the spontaneity of the reaction. Toward the end of the 19th century, however, the second law of thermodynamics was postulated and entropy,  $S$ , was defined. The property, entropy, is a single-valued function of the variables of the state of the system and may be defined as

$$\Delta S = \Delta Q_{rev}/T \quad (20)$$

where  $\Delta S$  is the change of entropy of the system,  $\Delta Q_{rev}$  is the heat change for the process carried out reversibly, and  $T$  is the absolute temperature. After entropy had been defined it was shown that the true criterion of spontaneity is not the sign of  $\Delta H$  but, instead, is the sign of  $\Delta H - T\Delta S$ . This quantity is designated  $\Delta G$  and is called the change in Gibbs energy, defined as

$$\Delta G = \Delta H - T\Delta S \quad (21)$$

Even though the sign of  $\Delta H$  is not the true criterion of the spontaneity of the reaction, it still may be an indication. The value of  $T\Delta S$  for many reactions at low temperatures is only of the order of a few thousand calories. Therefore, at low temperatures if the value of  $\Delta H$  is of the order of tens of thousands of calories or more it will probably have the same sign as  $\Delta G$ , and may be used as an indication of the spontaneity of the reaction. For more rigorous calculations it is necessary to have values of  $\Delta S$  as well as values of  $\Delta H$ . Values of  $\Delta H$  are also required to establish the magnitude of the temperature dependence of the Gibbs energy, which will be discussed in the following sections.

Similar in definition to the Gibbs energy is the Helmholtz energy, named for H. L. F. von Helmholtz. It is defined as

$$\Delta A = \Delta E - T\Delta S \quad (22)$$

where  $\Delta A$  is the change in the Helmholtz energy,  $\Delta E$  is the change in internal energy, and  $T$  and  $\Delta S$  are the absolute temperature and change in entropy of the process, as in equation (21). For most chemical purposes  $\Delta G$  is a more useful function than  $\Delta A$ .

**Measurements of Gibbs Energy.**—After the formulation of the second law of thermodynamics and the definition of Gibbs energy, chemists turned to direct measurements of Gibbs energies. They did not yet know how to make direct measurements of entropies for use in equation (21) to supplement enthalpy data in obtaining the desired criterion of spontaneity. The two techniques used for direct measurements of the Gibbs energy depend on the relationships between the Gibbs energy and (1) the equilibrium constant of a reaction, and (2) the electromotive force generated in a reversible electrolytic cell reaction.

The equilibrium constant,  $K$ , for a reaction

is defined as

$$K = [C]^c[D]^d \dots / [A]^a[B]^b \dots \quad (24)$$

where  $K$  is the equilibrium constant and  $[A]$ ,  $[B]$ ,  $[C]$ , and  $[D]$  are the concentrations of substances A, B, C, and D. This equilibrium expression, first enunciated by the Norwegian chemists C. M. Guldberg and Peter Waage in 1864, is often called the law of mass action. It may be derived from the fact that at equilibrium the rate constant ( $K$ , in the statement that rate of a reaction,  $aA + bB + \dots = \text{products}$ , is equal to  $k[A]^a[B]^b \dots$ ) for the reaction going forward is equal to the rate constant for the

reaction proceeding in the reverse direction. For gases it is more convenient to use partial pressures than concentrations in obtaining the equilibrium constant. For ideal mixtures the actual concentrations in molecules per unit volume may be used. In the case of gases at normal temperatures and pressures the assumption of ideal mixtures is quite accurate. However, at high pressures and low temperatures corrections for nonideality must be made. The equilibrium constant can be shown to be related to the Gibbs energy by the equation

$$\Delta G^\circ = -RT \ln K \quad (25)$$

where  $\Delta G^\circ$  is the standard Gibbs energy change for the reaction—the superscript  $^\circ$  indicating that the thermodynamic property refers to the reaction in which all the reactants and products are in their respective standard states (see below); and where  $R$ ,  $T$ , and  $\ln K$  are the gas constant, absolute temperature, and natural logarithm of the equilibrium constant, respectively.

The value of  $K$  can be obtained by measuring the equilibrium concentrations or pressures of a reaction in equilibrium and substituting these in equation (24). From  $K$  the  $\Delta G$  for the reaction can be calculated by the use of equation (25). Conversely—and this is an important reason why chemists are interested in Gibbs energy values—if the value of  $\Delta G$  is known, the equilibrium constant and relative concentrations of reactants and products in the reaction can be calculated. If a table of  $\Delta G^\circ$  values for different temperatures is available, the optimum operating conditions of temperature and pressure for the production of a desired product may be calculated.

The other method of experimentally determining the Gibbs energy is by measuring the electrical potential obtained from a chemical cell under reversible conditions. Then

$$\Delta G = -n\mathcal{F}\mathcal{E} \quad (26)$$

in which  $\Delta G$  is the Gibbs energy,  $n$  is the number of faradays of charge passing through the cell,  $\mathcal{F}$  is the number of charges in one faraday of electricity, and  $\mathcal{E}$  is the electromotive force generated by the cell under reversible conditions.

**Enthalpy Change and the Variation with Temperature of Other Quantities.**—It can be shown that the Gibbs energy change varies with temperature according to the relation

$$[\partial(\Delta G/T)/\partial T]_p = \Delta H/T^2 \quad (27)$$

where the left-hand term is the rate of change in the value of  $\Delta G/T$  with temperature at constant pressure,  $\Delta H$  is the enthalpy change, and  $T$  is the absolute temperature of the reaction. Substitution of equation (25) in equation (27) leads to the relation

$$(\partial \ln K / \partial T)_p = \Delta H^\circ / RT^2 \quad (28)$$

where the left-hand term is the rate of change in the value of the natural logarithm of the equilibrium constant with temperature at constant pressure,  $\Delta H^\circ$  is the enthalpy change of the reaction under standard conditions,  $R$  is the gas constant, and  $T$  is the absolute temperature.

It can also be shown that for the electrical cell reaction

$$\Delta H = n\mathcal{F}[T(\partial \mathcal{E} / \partial T)_p - \mathcal{E}] \quad (29)$$

where  $\Delta H$  is the enthalpy change for the reaction,  $(\partial \mathcal{E} / \partial T)_p$  is the rate of change in potential of the cell with temperature at constant pressure, and  $n$ ,  $\mathcal{F}$ , and  $\mathcal{E}$  are defined in equation (26).

The above relations are important because they show that a knowledge of values of  $\Delta H$  aids in the calculation of values of the Gibbs energy change, equilibrium constant, or potential of a cell at another temperature if they are known for one temperature. Conversely, from a knowledge of the variation of these quantities with temperature the values of  $\Delta H$  may be calculated; indeed, many values of  $\Delta H$  have been obtained in this manner rather than from strictly thermochemical measurements. However, the direct thermochemical measurement inherently leads to values of smaller uncertainty if the reaction can be carried out cleanly in a calorimeter.

**Measurement of Entropy.**—It was mentioned above that chemists turned first to direct measurement of  $\Delta G$  because they

could not measure  $\Delta S$  for use in the equation  $\Delta G = \Delta H - T\Delta S$ . This situation continued until the formulation of the third law of thermodynamics early in the 20th century. The third law states that the entropy of any substance of which all component parts are in complete internal equilibrium becomes zero at the absolute zero of temperature. With this law the entropy of a substance could be obtained at any temperature if measurements could be made of all the heat changes it underwent in proceeding from absolute zero to the desired temperature, since by definition (equation 20) the entropy is the sum of the heat changes the substance undergoes—each heat change to be carried out reversibly and to be divided by the absolute temperature at which it occurs.

Announcement of the third law was soon followed by the development of techniques for making low-temperature thermal measurements. From these measurements accurate enthalpy values could be calculated for use in equation (21) to obtain Gibbs energy values. This circumstance brought a renewed demand for accurate  $\Delta H$  determinations, since  $\Delta S$  could now be determined accurately; the  $\Delta H$  values were needed to determine  $\Delta G$  values themselves, rather than only their temperature coefficients as in equation (27). Both methods mentioned earlier for determination of  $\Delta G$  directly are often uncertain, mainly because of the difficulty of defining the reaction with sufficient accuracy. Furthermore, there are a large number of substances, especially among organic compounds, for which values of  $G$  cannot be determined from equilibrium measurements. Consequently, determinations of entropies from low-temperature measurements are extremely important.

### TABLES AND CALCULATIONS

The primary goal of the thermochemist is to provide tables of thermochemical data from which the enthalpy change of every possible reaction may be obtained. It is apparent that tabulation of the enthalpy changes of every reaction as measured would be haphazard. Further, it is both impossible and unnecessary to measure the heat of every possible reaction. Unfortunately, it is impossible to know the absolute value of the enthalpy of any substance; if it were, the values could be tabulated for all substances, and enthalpy changes for the reactions could be calculated in a straightforward manner. However, there is a way to tabulate enthalpy quantities for each substance which works very well.

**Hess's Law.**—First we must consider the law of constant heat summation. This law, first enunciated by G. H. Hess of Russia in 1840, states that the heat absorbed or evolved in any reaction is a fixed quantity and is independent of the path of the reaction or the number of steps taken to obtain the reaction. Hess's law is a consequence of the first law of thermodynamics and need not be considered a separate thermodynamic law; in thermochemistry, however, it retains its identity because of its importance as the basis of calculations. Hess's law is exemplified by the calculation of the heat of formation of carbon dioxide from its elements. (The heat, as the term is used by thermochemists, of a specified reaction is a short way of saying heat content or enthalpy change.) This reaction is represented by

(In this and all following thermochemical equations the letters c, g, and l in parentheses denote crystalline, gaseous, and liquid phases, respectively. Sometimes the temperature of the substance is indicated by a subscript. Following the semicolon the enthalpy change for the reaction, expressed in kilocalories [1 kcal = 1,000 cal], is given.)

In accordance with Hess's law the heat of formation of carbon dioxide is the same whether it occurs in one reaction as represented by equation (30) or in two steps as represented by the sum of equations (31) and (32):

The sum of equations (31) and (32) is

Thus Hess's law allows the calculation of the heats of various reactions from the heats of other reactions.

**Standard States.**—It is relevant at this point to discuss stan-

dard states. In reaction (31) one mole of  $\text{CO(g)}$  is formed. In reaction (32), one mole of  $\text{CO(g)}$  is used up. When the two equations are added, one mole of  $\text{CO(g)}$  in the state of reaction (32) appears on the left-hand side of the arrow and one mole of  $\text{CO(g)}$  in the state of reaction (31) appears on the right-hand side. If, and only if, these two moles of  $\text{CO(g)}$  are in identical states, they may be omitted from equation (30), because there is no enthalpy difference between them. It is convenient, therefore, to write thermochemical equations with each compound in a certain reference state. In equations (30), (31), and (32) the superscript  $^\circ$  following  $\Delta H$  indicates that the enthalpy change given is for the reaction in which each reactant and each product appears in its so-called standard state. Consequently it is permissible to omit the  $\text{CO(g)}$  in the sum of equations (31) and (32).

The standard states that have been chosen as reference states for thermochemical purposes are the following:

1. For solids, the pure crystalline solid in a common crystalline form (usually the most stable form) at one atmosphere pressure at the specified temperature.
2. For liquids, the pure liquid at one atmosphere pressure at the specified temperature.
3. For gases, the pure gas at zero pressure at the specified temperature.

It is apparent that thermochemical measurements must take into account, as precisely as possible, the state of each reactant or product. The measured heat change for the actual process may then be corrected to give the heat change for the idealized reaction in which all the reactants and products appear in their respective standard states at the specified temperature.

**Heats of Formation.**—Let us return to the consideration of thermochemical tables from which the heats of various reactions may be calculated. The quantity that is tabulated is the heat of formation of the substance at  $25^\circ \text{C}$  ( $298^\circ \text{K}$ ) when its elements and the compound itself are in their standard states. This quantity is called the standard heat of formation at  $25^\circ \text{C}$ , or  $298^\circ \text{K}$ , and is designated  $\Delta H_f^\circ$ . Standard heats of formation of some simple compounds are listed in Table I.

TABLE I.—Heats of Formation at  $25^\circ \text{C}$ , in kcal/mole

$\text{CH}_4(\text{g})$	...	...	...	...	-17.895
$\text{CO}_2(\text{g})$	...	...	...	...	-94.054
$\text{CO}(\text{g})$	...	...	...	...	-26.417
$\text{H}_2\text{O}(\text{g})$	...	...	...	...	-57.798
$\text{H}_2\text{O}(\text{l})$	...	...	...	...	-68.317

Note.— $\Delta H_{\text{vap}}^\circ(\text{H}_2\text{O}) = \Delta H_f^\circ(\text{H}_2\text{O, g}) - \Delta H_f^\circ(\text{H}_2\text{O, l}) = -57.798 - (-68.317) = +10.519 \text{ kcal/mole}$

**Calculation of Heats of Reaction.**—From a thermochemical table such as Table I the standard heat of reaction of any reaction at  $25^\circ \text{C}$  may be calculated, provided heat-of-formation values appear in the table for each reactant and each product. The calculation may be carried out in the following steps:

1. Each reactant is decomposed to its elements.
2. From the elements the products are synthesized.
3. The sum of the heats of the decomposition reactions and the heats of the synthesis reactions is the heat of the reaction sought.

A simple example of the procedure is the calculation of the heat of the reaction in which gaseous methane and carbon dioxide may react to produce carbon monoxide and liquid water:

First the reactants are decomposed to their elements:

(Note that the crystalline state of the carbon has been exactly specified. Each of its several allotropic forms—diamond, graphite, lampblack, charcoal—has a different heat content. For some data compilations the most stable form, diamond, has been used for the standard state; in the present calculations, graphite is preferred, in accordance with more modern practice.)

Then the products are synthesized from the elements:

The sum of reactions (34) to (37) is

It should be noted that  $\Delta H$  is always the enthalpy change of the reaction as written. Thus for equations (36) and (37),  $\Delta H^\circ$  is four times and twice the molal heat of formation of the compounds, respectively. Equations (34) and (35) are decomposition reactions; therefore  $\Delta H^\circ$  is respectively one and three times the heats of formation, with the sign changed.

Heats of formation are only special cases of heats of reaction. Just as heats of formation are used to calculate the heats of various desired reactions, the heats of reaction that can be measured easily are used to calculate unknown heats of formation. In fact, most heats of formation are obtained indirectly from measurements of heats of reactions involving the substance of unknown heat of formation. Consider, for example, the problem of obtaining the heat of formation of methane. It would be extremely difficult, if not impossible, to carry out the reaction between graphite and hydrogen in a calorimeter to yield methane alone—although the heat of this reaction, if corrected to standard-state conditions, would be the standard heat of formation of methane. It is, however, possible to burn methane in oxygen to obtain carbon dioxide and water:

To obtain from this the heat of formation of methane it is necessary to have heat-of-formation data for  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$ . If these were not available it would also be necessary to burn hydrogen in oxygen to give water and to burn carbon in oxygen to give carbon dioxide. (The following equations for the heats of formation of the appropriate amounts of water and carbon dioxide are written in reverse for convenience and the sign of  $\Delta H$  is appropriately marked for the way the equations are written.)

The sum of equations (39), (40), and (41) is

Equation (42) represents the formation of one mole of methane from its elements in their standard states. Since the equation is written in reverse, the heat of formation of methane is  $-17.895$  kcal/mole.

**Variation of  $\Delta H$  with Physical State.**—In equation (38) the water formed is liquid. To calculate  $\Delta H$  for the reaction in which gaseous water (steam) is formed, a value for the standard heat of vaporization of water at  $25^\circ$  is taken from Table I; then

The sum of equations (38) and (43) is

The same result would have been obtained if equation (37), and consequently (38), had been written so that steam was formed.

**Variation of  $\Delta H$  with Temperature.**—It is also of interest to know how the value of  $\Delta H$  varies with temperature. For these calculations, values of the difference in  $H$  between the desired temperature and the reference temperature,  $25^\circ \text{C}$  ( $298^\circ \text{K}$ ), of equation (44) are needed for each reactant and product. Such values are included in Table II. In the preceding calculations the temperature of all the reactions was at the standard reference temperature of  $25^\circ \text{C}$  ( $298^\circ \text{K}$ ) and was not specified in the reactions. In the following four equations, which lead to the  $\Delta H$  value for equation (44) at  $2,000^\circ \text{K}$ , temperature must be specified:

The sum of equations (44) through (48) is the following equation,

in which all the reactants and products are at  $2,000^\circ \text{K}$  (indicated by the  $2,000^\circ \text{K}$  subscript to  $\Delta H^\circ$ ):

In the above calculation the temperature variation was very large. For calculations involving small temperature changes the variation of  $H$  with temperature may be taken as constant and the heat capacity at constant pressure may be used in the calculations. From equation (17),  $\Delta H/\Delta T = C_p$ , or  $\Delta H = C_p \Delta T$ . Therefore, for any substance undergoing a small temperature change from  $T_1$  to  $T_2$  the enthalpy change,  $H_{T_2} - H_{T_1}$ , is equal to  $C_p(T_2 - T_1)$ .

The following equations show how  $\Delta H$  for the reaction  $\text{A} + \text{B} \rightarrow \text{C}$  varies between temperatures  $T_1$  and  $T_2$ :

$$\text{A}_{T_1} + \text{B}_{T_1} \rightarrow \text{C}_{T_1}; \Delta H = \Delta H_{T_1} \quad (50)$$

$$\text{A}_{T_2} \rightarrow \text{A}_{T_1}; \Delta H = C_p(\text{A})(T_1 - T_2) = -C_p(\text{A})(T_2 - T_1) \quad (51)$$

$$\text{B}_{T_2} \rightarrow \text{B}_{T_1}; \Delta H = C_p(\text{B})(T_1 - T_2) = -C_p(\text{B})(T_2 - T_1) \quad (52)$$

$$\text{C}_{T_1} \rightarrow \text{C}_{T_2}; \Delta H = C_p(\text{C})(T_2 - T_1) \quad (53)$$

The sum of these four reactions is

Because  $C_p(\text{C}) - C_p(\text{A}) - C_p(\text{B})$  is the heat capacities of the products minus the heat capacities of the reactants, this quantity may be designated  $\Delta C_p$ . The term  $T_2 - T_1$  is  $\Delta T$ , so

$$\Delta H_{T_2} - \Delta H_{T_1} = \Delta C_p \Delta T \quad (55)$$

or, for the reaction

$$\Delta(\Delta H)/\Delta T = \Delta C_p \quad (56)$$

Equation (56) is a mathematical statement of Kirchhoff's law, first deduced by the German physicist Gustav Kirchhoff in 1858. The law asserts that the temperature coefficient,  $\Delta(\Delta H)/\Delta T$ , of the heat of a reaction under any circumstance is equal to the change in the heat capacity which the system undergoes under this circumstance.

**Relation of  $\Delta H$  to  $\Delta G$ .**—In the preceding paragraphs calculations were made of the enthalpy changes for the reaction of methane with carbon dioxide to form carbon monoxide and water under different conditions of the physical state of the water formed and of the temperature at which the reaction occurred. The role of thermochemical calculations in thermodynamic calculations can be shown by proceeding further into thermodynamics and calculating the Gibbs energy changes for reaction (44), in which water vapour and carbon monoxide are formed at  $298^\circ \text{K}$  and at  $2,000^\circ \text{K}$ . Values of the entropy,  $S$ , for each reactant and product can be obtained from Table II. From these,  $\Delta S$ , the sum of the entropies

TABLE II.—Chemical Thermodynamic Properties

$^\circ \text{K}$	$\text{CH}_4(\text{g})$	$\text{CO}_2(\text{g})$	$\text{CO}(\text{g})$	$\text{H}_2\text{O}(\text{g})$
For $H^\circ_f - H^\circ_{298}$ in kcal/mole				
298	0.000	0.000	0.000	0.000
500	1.960	1.987	1.417	1.654
1,000	9.125	7.984	5.183	6.209
2,000	29.540	21.857	13.561	17.373
For $S^\circ$ in cal/deg/mole- $^\circ$				
298	44.490	51.072	47.214	45.106
500	49.453	56.122	50.841	49.334
1,000	59.141	64.344	56.028	55.592
2,000	73.076	73.903	61.807	63.234

of the products minus the sum of the entropies of the reactants, and the product  $T\Delta S$  may be computed for each temperature.

$$\Delta S_{298} = 81.362 \text{ cal/deg}, T\Delta S_{298} = 24.246 \text{ kcal} \quad (57)$$

$$\Delta S_{2,000} = 78.911 \text{ cal/deg}, T\Delta S_{2,000} = 157.822 \text{ kcal} \quad (58)$$

From the relation  $\Delta G = \Delta H - T\Delta S$  the Gibbs energy change for reaction (33) for each temperature is calculated to be

$$\Delta G_{298} = +54.547 \text{ kcal} \quad (59)$$

$$\Delta G_{2,000} = -85.150 \text{ kcal} \quad (60)$$

From these values the equilibrium constant or relative concen-

trations for the reaction at these two temperatures can be calculated. It would be found that no significant amounts of methane and carbon dioxide react to form carbon monoxide and water at 298°, but the reaction goes substantially to completion at 2,000° K. In actual practice the engineer would make the calculations for many intermediate temperatures to find the most economical conditions for carrying out the reaction.

**Summary.**—Thermochemistry is an experimental science. Its goal is to complete a table of the standard heats of formation of every substance in every state at 25° C—a table from which the standard heats of every possible reaction at 25° C may be calculated. The adjunctive use of tables of other thermodynamic properties then permits the calculation of heats of reaction at other temperatures and for a variety of conditions of physical state, pressure, and the like. These heats of reaction, used in combination with tables of entropy values, give the Gibbs energy changes for the reactions; and from the heats of reaction the variation with temperature of the Gibbs energy, equilibrium constants, and reversible cell potentials may also be calculated.

Values of the standard heats of formation of each substance are best determined by direct measurements of the enthalpy, or total energy change, of a reaction in which the substance is involved. These values may also be obtained from measurements of equilibrium constants or reversible cell potentials as a function of the temperature of the reaction, or from free energies obtained from equilibrium constants or reversible cell potentials if accurate entropy data are available.

Measuring thermochemical quantities is the chief activity in many university, government, and industrial laboratories. In the United States the collection, appraisal, and tabulation of existing thermochemical data has been undertaken cooperatively by government agencies (notably the Department of Defense) and industrial interests.

**THERMOCOUPLE**, used as a form of thermometer, basically is a pair of unlike metals or alloys (commonly wires) joined at each end. Electricity flows in the couple (Seebeck effect) in rough proportion to the degree that one end or junction is hotter than the other (see THERMOELECTRICITY). Temperatures at one junction can be measured through voltmeter readings (calibrated in degrees) when the other is kept at a known reference level (often 0° C [32° F]). Sensitivity may be increased by using connected thermocouples (a thermopile) in series; such devices for relatively rough work are typically accurate to about  $\pm 2^\circ \text{C}$  ( $\pm 3.6^\circ \text{F}$ ), precision to about  $\pm 0.06^\circ \text{C}$  ( $\pm 0.1^\circ \text{F}$ ) being obtainable in special cases. As a less fragile replacement for glass thermometers, a given thermocouple device will function usefully in a portion of the range from about  $-260^\circ$  to  $1,600^\circ \text{C}$  ( $-436^\circ$  to  $2,912^\circ \text{F}$ ).

**THERMODYNAMICS** may be defined broadly as the study of the role of heat in transformations of matter or energy. More narrowly it is the mathematical application of three general laws, derived from countless experimental observations of heat changes, to a variety of problems in theoretical chemistry and physics and in engineering.

The foundation of thermodynamics is its first law, commonly known as the law of conservation of energy. Largely self-evident, it is a scientific axiom paralleling the law of conservation of

matter (or mass). The second law of thermodynamics, which can be variously stated and is sometimes called the law of entropy (dissipation of energy), is as fundamental as the first law but required much experimental verification for its acceptance. It was the early investigations of the many ramifications of the second law, initially tested in the operation of heat engines, that established thermodynamics as a discipline and led to its application in fields as seemingly remote as chemical engineering and astrophysics. The third law, which is concerned with entropy at or near the absolute zero of temperature, derives from the second law and has an important part in modern conjecture about the ultimate states of matter.

The history of thermodynamics is closely bound up with the general progress of chemistry and physics since the mid-19th century. (See further CHEMISTRY: *The Founding of Physical Chemistry*; PHYSICS: *GENERAL SURVEY: Theory*.) Because of its pervasive nature, thermodynamics is not easily delimited in relation to other disciplines. It partakes of and contributes to a dozen fields; yet it has its own traditions and methods, and therefore has developed a characteristic viewpoint and a distinctive way of presenting its findings. It has also fostered branches that reflect the parent methodology; such, for example, is thermochemistry (*q.v.*), the study of heat absorbed and evolved in chemical reactions. As for the limits of thermodynamics: their ambiguity is exemplified by statistical mechanics (*q.v.*), alternatively known as statistical thermodynamics—a subject which can be considered either as an extremely refined and wide-ranging mathematical treatment of the second law or as a special discipline occupying a position between thermodynamics proper and molecular or atomic physics. Preliminary reference to the article HEAT will give the reader a fuller sense of the scope and limitations of thermodynamics than can readily be conveyed here.

This article has the following main divisions and sections:

## I. FIRST LAW OF THERMODYNAMICS

**1. Definitions: Energy, Work, and Heat.**—The primary physical concept of work is the movement of a body against an opposing force, and the work done is the product of the distance moved multiplied by the component of the opposing force in the direction of motion. If the opposing force is due to the pressure on a piston, the force is the pressure times the area of the piston, while the volume swept through by the piston, or the volume change of the fluid opposing the piston, is the distance through which the piston moves times the same area. Hence the work done on a fluid is its pressure times its decrease in volume, and

conversely the work done by a fluid is its pressure times its increase of volume. In general, a delta ( $\Delta$ ) is used before a symbol to indicate the new value minus the old; in the above case the change of volume will be written  $\Delta V$ , to represent  $V_{\text{new}} - V_{\text{old}}$ , which will be inherently positive or negative according as the new volume is greater or less than the old. With this convention we write  $w = P\Delta V$ , where  $w$  uniformly represents the work done by the system by virtue of its change of volume. In general we represent by  $w$  the work done by the system of interest, which, if negative, is interpreted as work done upon the system by some external agency.

The capacity of a system to do work can be exchanged with that of other systems in a variety of ways. Generally the capacity of the combined systems is diminished in such interchanges, but with great care to minimize losses by friction and other dissipative processes, exchanges of capacity to do work may be carried out with negligible loss. An idealized process with no dissipation is called a reversible process.

The capacity to do work possessed by a body by virtue of its being at a higher gravitational level than some arbitrarily chosen level is called gravitational potential energy, or energy of position. Usually we find a correlation between the capacity of a system to do work and what we call its energy. (See MECHANICS: *Work and Energy Relations*.) One of the simplest transformations of energy occurs in a nearly frictionless pendulum (see ENERGY: *Kinetic Energy*), in which potential energy is converted to kinetic energy, or energy of motion, which is then reconverted to potential energy. At the end of the swing all the energy is potential, at the bottom it is all kinetic, and in intermediate positions part is potential and part is kinetic—but when friction is negligible the sum remains constant. When friction (*q.v.*) is present the swings become shorter and shorter, and finally the pendulum comes to rest in its lowest position, at which time it has lost both its potential and its kinetic energy. Is this a destruction of energy, or another transformation? Experiments of other types indicate that the dissipation of gravitational potential energy in a thermally insulated system causes its temperature to rise. A similar rise in temperature can be produced in an initially similar system by putting it in contact with a hot body, in which case we find that the hot body is cooled by the contact. We say that heat flows from the hot body to the relatively cool one. Since this heat may be supplied to the body either by contact with the hot one or by dissipation of potential energy by friction, we infer that heat is a form of energy, and that by friction, potential energy has been transformed into heat. (See also ENERGY: *Heat as a Form of Energy*.)

Before we can make such an inference quantitative we must devise methods for the measurement of heat and of energy. The change of gravitational potential energy of a body with height is proportional to the product of the change of height and the mass of the body; the common English engineering unit of energy, called the foot-pound, is defined as the work needed to raise one pound of mass a vertical distance of one foot. However, the energy is also proportional to the acceleration due to gravity, and in most scientific work the potential energy is expressed by  $mgh$ , with  $m$  the mass in grams,  $g$  the acceleration in  $\text{cm}\cdot\text{sec}^{-2}$ , and  $h$  the change of height in centimetres. In this system (the centimetre-gram-second, or cgs, system) the unit of energy is expressed in  $\text{g}\cdot\text{cm}^2\cdot\text{sec}^{-2}$ , and is called the erg. In the related metre-kilogram-second system, the unit of energy is expressed in  $\text{kg}\cdot\text{m}^2\cdot\text{sec}^{-2}$ , and is called the joule. The kinetic energy in either system is given by  $\frac{1}{2}mv^2$ .

Flow of heat is expressed in terms of the change of temperature which each body undergoes when two bodies are placed in thermal contact. The heat absorbed by one body is found to be equal to that given up by the other if we write the heat absorbed,  $q = mC\Delta t$ , where  $m$  is the mass,  $\Delta t$  is the new temperature minus the old, and  $C$ , called the specific heat capacity (see CALORIMETRY), is a quantity characteristic of the substance, which usually changes only slightly with temperature unless a change of state or of crystalline structure occurs. (Such a change of state is frequently accompanied by an additional absorption of heat, called

the latent heat; *q.v.*) The unit of heat called the calorie (*q.v.*) is commonly defined as that amount required to raise the temperature of one gram of water from 14.5 to 15.5° C, which makes the specific heat of water at 15° equal to one  $\text{cal}\cdot\text{g}^{-1}\cdot\text{deg}^{-1}$ . For many uses the kilocalorie (1,000 calories; abbreviated kcal) is a more convenient unit.

**2. Statement of the Law.**—Holding to these definitions of potential and kinetic energy and of heat, it is found that whenever a quantity of potential or kinetic energy is dissipated by friction or some other dissipative process, an amount of heat appears which is proportional to the energy dissipated. Also, when heat is used to produce work, the amount of heat is diminished in proportion to the work done, by the same factor of proportionality. The proportionality factor has been found to be 4.1833 international joules per calorie. Since work and heat are both forms of energy they can both be expressed in joules, calories, or other units of energy. In the equations that follow it will be assumed that both are expressed in the same units; therefore no proportionality factor is needed.

Chemical transformations, the discharge of an electric condenser, the demagnetization of a magnet, and many other processes can do work or produce heat. It is convenient to assign an energy to each state such that the change of energy is the energy in the final state minus that in the initial state. When the above definitions and conventions are observed, the first law of thermodynamics, or the law of conservation of energy, may be stated thus: *For all changes in an isolated system, the energy remains constant.*

**3. Experimental Confirmation.**—As a consequence of this principle, for any change from state A to state B we expect the change of energy to be independent of the intermediate steps in the process. As an example, for the reaction

carried out in a calorimeter, the energy liberated as heat has been found in three investigations to be 15.30, 15.30, and 15.18 kcal respectively. For the dissolution of  $\text{Ca}(\text{OH})_2$  in aqueous HCl (200 moles  $\text{H}_2\text{O}$  per mole HCl)

the liberation of heat was found in two investigations to be 30.49 and 30.82 kcal. By the law of conservation of energy, the sum of the heats for reactions (a) and (b) should be the heat for reaction

The sum of the averages for (a) and for (b) is 45.92, while the result of direct measurement is 46.45 kcal. The discrepancy is believed to be due to experimental error, although some of the difference may be due to slight differences in the crystalline state of the CaO used in (a) and (c), and in that of the  $\text{Ca}(\text{OH})_2$  produced in (a) and used in (b).

The above example is fairly typical of a large body of experimental data in reasonably good accord with the principle of conservation of energy. Under favourable conditions the agreement is much better, but in other cases it is not as good. The cases of poor agreement can be explained by failure to provide sufficiently good isolation, but it is difficult to give independent criteria for isolation. An interesting example is the energy loss of radioactive material undergoing beta decay, which is presumably the same for each atom of the material which decays, and is expected to be equal to or greater than that for the most energetic beta particle emitted. However, the calorimetrically measured energy, when the energy is dissipated in an absorbing material, is appreciably less than that calculated from the energy of the most energetic beta particles. The commonly accepted explanation is that neutrinos are emitted along with the beta emission, and that they carry away some of the energy. Fortunately for this explanation, the existence of the neutrino is in accord with other conservation laws; but the difficulty of stopping neutrinos or of detecting their passage casts doubt on the possibility of demonstrating the establishment of a truly isolated system. By far the best reasons for accepting the first law of thermodynamics, along with the second (see below), are that a large number of corollaries have been de-

rived from either, or both in combination, and in no case has such corollary been found inconsistent with experiment. As a result, the first law of thermodynamics is regarded as one of the best-established laws of the physical sciences.

**4. The First Law and Relativity.**—According to the principle of relativity, energy and mass are related according to the equation  $E = mc^2$  where, if  $m$  is the mass in grams and  $c$  is the velocity of light in centimetres per second,  $E$  is the energy in ergs. This relation does not assert the transformation of mass into energy; rather, it asserts the equivalence of mass and energy. An isolated system containing radioactive material which emits alpha particles undergoes no change of mass. The rest mass of the daughter nuclei is less than that of the parent, but the mass of the liberated energy is equal to this difference, and the system loses mass only when the energy is lost from the system. In principle the mass-energy equivalence seems to give a means of measuring the energy of the system by measuring its mass. In practice this is useful only in nuclear transformations, for the change of mass corresponding to the energy change of most other processes is too small to be measured. Furthermore, the attempt to measure the total energy of the system by measuring its mass gives only the energy relative to the chosen inertial system.

## II. SECOND LAW OF THERMODYNAMICS

Under this heading we will first consider implications of the first law of thermodynamics that lead toward the second law: (1) the general principles governing exchanges of energy between systems; (2) the application of these principles to the reversible expansion of an ideal gas; and (3) the thermodynamic relationships epitomized in the Carnot cycle. The second law can then be stated and, in the sections following, some of the applications of the law to a variety of physical and chemical phenomena will be explored.

**1. Energy Exchange.**—According to the principle of conservation of energy, a system can gain energy only by interaction with other systems in such a way that the other systems lose a corresponding amount of energy. A gain of energy by conduction or by thermal radiation is called a flow of heat, while energy exchanged by other mechanisms is called work. It is customary to use  $q$  for the heat absorbed or gained by the system, and  $w$  for the work done by the system; so that, for any process,

$$\Delta E = q - w \quad (1)$$

where  $\Delta E$  is the increase of energy of the system,  $q$  is the energy gained by thermal flow (either by conduction or by thermal radiation), and  $w$  is the energy lost by the system because of other interactions, such as moving a body against an opposing force, producing an electric current, etc. While heat is most frequently measured in calories, and work in joules or other work units, either heat or work can be measured in units which are traditionally associated with the other (since both are forms of energy). Except when numerical results are given, it is usually unnecessary to specify the units being employed, but it will be assumed that when both heat and work occur in the same relation, we use the same units for both.

**2. Applications to Ideal Gases.**—The behaviour of gases on change of pressure or temperature is described approximately by the equations

$$PV = nRT \text{ and } (dE/dV)_T = 0 \quad (2)$$

where  $P$  is the pressure,  $V$  the volume,  $n$  the number of moles (the number of grams divided by the gram molecular weight), and  $T$  is the absolute temperature, or 273.15 plus the Celsius temperature.  $R$  is a constant whose numerical value depends on the units in which the other quantities are expressed (82.06 cm<sup>3</sup> atm-mole<sup>-1</sup> deg<sup>-1</sup>, 8.314 joule-mole<sup>-1</sup> deg<sup>-1</sup>, 1.986 cal-mole<sup>-1</sup> deg<sup>-1</sup>, and others), and  $(dE/dV)_T$  is the limit of the change of energy divided by the change of volume at constant temperature, as the change of volume approaches zero. A fictitious gas which obeys these relations is called an ideal gas. Actual gases deviate from these conditions, but as the pressure approaches zero,  $PV/nRT$  approaches unity and  $(dE/dV)_T$  approaches zero.

The work done by an expansion against a constant pressure is  $P\Delta V$ . For the expansion of an ideal gas at constant temperature the pressure continually decreases, and the work done is expressed by the integral:  $w = \int PdV = nRT \int dV/V = nRT \ln (V_f/V_i)$ , where  $V_f$  is the final volume and  $V_i$  is the initial volume. Since the energy of the ideal gas does not change at constant temperature,  $q = w$ , and the heat absorbed during the expansion is also  $nRT \ln (V_f/V_i)$ . It should be noted that the work done and the heat absorbed have been calculated for the reversible expansion of the gas. To expand in this manner would require that the opposing force exactly balance that due to the pressure of the gas; to carry out the expansion at a finite rate would require that the opposing force be slightly smaller to allow for friction or other source of loss, and in general the actual work done is less than that for the reversible process. The above result may be more precisely expressed  $w_{rev} = q_{rev} = nRT \ln (V_f/V_i)$  or  $q = w \leq nRT \ln (V_f/V_i)$ .

When no heat flows during the expansion, the process is called an adiabatic expansion. In this case  $q = 0$  and  $\Delta E = -w$ . For infinitesimal reversible expansion  $-PdV = dE = nC_v dT$ , where  $C_v$  is the heat absorbed by a mole of gas per degree rise in temperature, when heated at constant volume. Replacing  $P$  by  $nRT/V$ , then  $nC_v dT = nRT dV/V$ , or  $(C_v/R) dT/T = -dV/V$ . If  $C_v$  does not change with temperature, we obtain, by integrating,

$$(C_v/R) \ln (T_f/T_i) = -\ln (V_f/V_i) \quad (3)$$

From  $PV = nRT$  we obtain  $\ln (T_f/T_i) = \ln (P_f/P_i) + \ln (V_f/V_i)$ , and by adding to both sides of (3) we obtain

$$\ln (P_f/P_i) = (C_p/R) \ln (T_f/T_i) \quad (4)$$

The amount of heat absorbed by a mole of an ideal gas, per degree rise in temperature, when heated at constant pressure, is greater than  $C_v$  by the work done in pushing away the surroundings. The difference is easily shown to be  $R$ , and the heat capacity per mole of the ideal gas at constant pressure,  $C_p = C_v + R$ . Substituting this in (4), we obtain

$$\ln (P_f/P_i) = (C_p/R) \ln (T_f/T_i) \quad (5)$$

An interesting application of cooling by adiabatic expansion occurs on the rise of air in the atmosphere, due either to thermal

ISOTHERMAL AND ADIABATIC EXPANSIONS OF AN IDEAL GAS

Curves AB, BC, CD, and DA represent successively a threefold isothermal compression at 300° K (approximately 27° C or 80° F), adiabatic compression from 300° to 600° K, a threefold isothermal expansion at 600° K, and adiabatic expansion from 600° to 300° K. The area enclosed by ABCD is a measure of the work obtainable by carrying out the cycle in a reversible manner.

convection or to a wind which forces it up the side of a mountain. For dry air,  $C_p/R$  is about 3.5; for a rise from sea level, at a pressure of 760 mm and temperature of  $17^\circ\text{C}$ , to a height of about 1 km, where the pressure is about 660 mm, the temperature drops to about  $7^\circ\text{C}$ . (See also HEAT: *Thermal Properties of Gases*.)

**3. The Carnot Cycle.**—Two examples have been given (see above) of the production of work by the expansion of a gas. In the first instance the expansion is said to be isothermal; in the second instance, adiabatic. In an isothermal expansion, heat from an outside body is converted to work; in an adiabatic expansion, work is done at the expense of the thermal energy of the gas. In each case the gas occupies more space at the end of the process than at the beginning. If the expansion is continued, a very large space is required to obtain a comparatively small additional amount of work. Furthermore, unless this space is empty the point is soon reached where the work required to push away the material occupying the space is greater than the work obtained from expanding the gas. If, after an isothermal expansion, the gas is restored to its initial volume by isothermal compression at the initial temperature, the same amount of work must be done as was obtained by the initial expansion, if done reversibly; if done irreversibly, more work is required.

Let us now consider the cycle first studied by the French physicist Sadi Carnot (*q.v.*; 1796–1832). In this cycle the gas is expanded isothermally at  $T'$  from  $V_1$  to  $V_2$ ; expanded adiabatically from  $V_2$  to  $V_3$ , simultaneously cooling from  $T'$  to  $T''$ ; compressed isothermally at  $T''$  to volume  $V_4$ ; and then compressed adiabatically until the temperature is again  $T'$ . By use of equations (2) and (3) it can be shown that if  $V_3/V_4$  is chosen to equal  $V_2/V_1$ , the final volume will be the same as the initial volume, and the gas will have been restored to its initial state. The work done by the gas during the adiabatic expansion is equal to the work required for the adiabatic compression, but the work done by the expansion at  $T'$  is  $nRT' \ln (V_2/V_1)$ , while the work required for the compression at  $T''$  is  $nRT'' \ln (V_2/V_1)$ . The net work from the complete reversible cycle using the ideal gas is then

$$w_{\text{rev, gas}} = nR(T' - T'') \ln (V_2/V_1) = -q'(T' - T'')/T' = q''(T' - T'')/T'' \quad (6)$$

where  $q'$  is the heat absorbed by the hot body (in this case a negative quantity) and  $q''$  is the heat absorbed by the cold body. The gas absorbs heat at the high temperature and gives up heat at the low temperature, but at the end of the cycle it is restored in every way to its initial state. The net result of the process is the loss of heat by the hot body, the gain of a somewhat smaller amount of heat by the cold one, and the conversion of some of the heat into work. (See also HEAT: *Carnot: On the Motive Power of Heat*.)

Note that by the operation of this cycle involving the alternate expansion and compression of an ideal gas, only part of the heat can be converted into work. The question immediately arises: Can some other cycle—such as the compression of liquid water, its evaporation, and the expansion of the resultant steam, followed by condensation at a lower temperature—effect a greater conversion of the heat of the hot body into work? If such a cycle can produce more work than the reversible gas cycle, then  $w_2 > w_1$  where  $w_1$  and  $w_2$  are the amounts of work obtainable by the gas cycle and the second cycle respectively, when equal amounts of heat are withdrawn from the body at  $T'$  and the appropriate amount of heat is rejected to the cold body at  $T''$ . We operate the second cycle, obtaining the work  $w_2$ , and then operate the gas cycle in reverse direction, returning to the body at  $T'$  the amount of heat which had been removed from it by the second cycle. We thus obtain the net work  $w_2 - w_1$  with the removal of an equivalent amount of heat from the cold body, and with no net change in the hot body. If, instead, the reversible operation of the second cycle yields a smaller amount of work,  $w_2 < w_1$ , we operate the gas cycle to obtain work, and reverse the second cycle. In this case, again choosing to restore to the hot body the same amount of heat which it had lost, the net work obtained is  $w_1 - w_2$ , with the sole other result being the removal of an equivalent amount of heat from the cold body.

**4. Statement of the Law.**—A cyclic process in which the net result is the restoration of all parts of the system to their initial states except for the removal of heat from a body, and the production of an equivalent amount of work, has been called a perpetual motion of the second kind. Such a process would be extremely useful, and the failure of all attempts to find such processes has led to the belief that it is impossible. The impossibility of perpetual motion of the second kind is the essence of the second law of thermodynamics. The law is commonly stated in a variety of fundamentally equivalent ways; a satisfactory one for our purposes is: *It is impossible to operate a cycle in which the only net effect is the absorption of heat from a body at constant temperature and the production of an equivalent amount of work.* The mere failure thus far to find a means to do this, provides a very weak basis for this principle. On the other hand, it is strongly supported by many corollaries which have been logically derived from the principle and which are in accord with experience.

Accepting the second law, or the impossibility of perpetual motion of the second kind, we note that for the same amount of heat taken from the hot body the work obtained by any reversible cycle operated between two temperatures is the same, and equal to that given by the ideal gas cycle (equation [6]). We may also note from this equation that  $q'/T' + q''/T'' = 0$  for the reversible cycle. If the process had been carried out irreversibly, the work done (for the same  $q'$ ) would have been less, and correspondingly, the heat absorbed by the cold body,  $q''_{\text{irr}}$ , would have been greater than  $q''_{\text{rev}}$ . In this case  $(q'/T' + q''/T'')_{\text{irr}}$  is greater than zero.

**5. Entropy.**—We define entropy such that in a reversible process any part of the system at temperature  $T$  which absorbs heat  $q_r$  is said to have increased its entropy by  $q_r/T$ . It can be shown that the change of entropy depends only on the initial and final states; hence we can find its change for any process, reversible or not, by considering the heat which would have been absorbed in reversible changes leading to the same final state. When a process is reversible the sum of all changes of entropy is zero; for any irreversible process the sum is positive. The commonly accepted symbol for entropy is  $S$ , and we summarize the above statements by  $\Delta S = q_r/T \geq q/T$  where  $q$  is the heat absorbed for the process as actually carried out, and  $q_r$  is the heat which would have been absorbed in carrying the system reversibly from the same initial to the same final state.

The three statements concerning change of entropy—that it depends only on the initial and final states, that it is zero for a reversible process, and that it is positive for an irreversible process—are of great importance, both for the determination of entropy and for the prediction of possible changes in systems.

#### Example 1

An ideal gas at  $20^\circ\text{C}$  and 2 atm pressure is allowed to leak slowly into an evacuated space of volume equal to that initially occupied by the gas, so that the final pressure is 1 atm. No energy change takes place in this process, i.e., no energy need be absorbed or given off; and the average velocity of the individual molecules is unchanged.

To get the entropy change of the system we need to consider a reversible process by which the gas changes from the given initial state to the same final state. Such a process is the reversible isothermal expansion, in which the work done, and likewise the heat absorbed, is  $nRT \ln 2$ . The entropy change of the gas is now  $q_{\text{rev}}/T = nR \ln 2$ , and the entropy change of the surroundings is  $-nR \ln 2$ , giving a total entropy change of zero, as expected for a reversible process. Since the initial and final states of the gas are the same as for the irreversible process in the example, the entropy change of the gas during the irreversible expansion is also  $nR \ln 2$ . The surroundings, however, in this case undergo no change, hence no change of entropy; the total change is now  $nR \ln 2 + 0 = nR \ln 2$ , a positive quantity, in accord with our expectation for an irreversible process.

#### Example 2

One gram atomic weight (112.4 g) of cadmium and one mole (159.8 g) of liquid bromine are mixed at  $36^\circ\text{C}$ . (The temperature  $36^\circ\text{C}$  is chosen because at lower temperatures the aqueous solution would be saturated not with anhydrous  $\text{CdBr}_2$  but with a salt possessing water of crystallization. A cell saturated with this salt would give nearly the same electromotive force, but exact calculations of the quantities we desire would be complicated. For any temperature the solubility of bromine in the aqueous solution and of water in the bromine call for slight corrections which can be neglected here for the sake of simplicity.) Reaction occurs with the formation of  $\text{CdBr}_2$  and the liberation of

75.20 kcal of energy, which is absorbed by the surroundings as heat. The change in the surroundings is the same as if the 75.20 kcal had been absorbed as part of a reversible process; hence  $\Delta S_{\text{sur}}$ , the change of entropy of the surroundings, is  $75.20 \times 1,000 / (273.15 + 36) = 243.3$  cal/deg. Since the combination of cadmium and bromine is not carried out reversibly under these conditions, the change of entropy of the cadmium-bromine system is not the negative of this.

The combination of cadmium and bromine at  $36^\circ \text{C}$  could have been carried out nearly reversibly by separating the cadmium and the bromine by a saturated aqueous solution of cadmium bromide, putting a platinum wire in the bromine-cadmium bromide end of the cell, and drawing electric current from it. While current flows, Cd and  $\text{Br}_2$  are consumed and solid  $\text{CdBr}_2$  precipitates from the aqueous solution; for the consumption of 1 gram atomic weight of Cd and 1 mole of  $\text{Br}_2$ , 2 faradays (193,000 coulombs) of electricity pass through the circuit. The maximum work which can be obtained from the passage of electricity is the product of the quantity of electricity which passes, and the potential difference, which is about 1.516 volts when the process is carried out reversibly. The electrical work for the reversible process is then  $1.516 \times 193,000$  joules, or 69.94 kcal, and the heat absorbed from the cell is greater than that absorbed for the direct combination by this amount. Accordingly,  $q_{\text{rev}} = -75.20 + 69.94 = -5.26$  kcal (i.e., 5.26 kcal are given to the surroundings), and the entropy change for the production of 1 mole of solid  $\text{CdBr}_2$  is  $-5.26 \times 1,000 / (273.15 + 36) = -17.0$  cal/deg. Since the initial and final states of the cadmium-bromine system are the same in the reversible and in the irreversible processes considered, the total change of entropy of the irreversible process is  $243.3 + (-17.0) = 226.3$  cal/deg.

We may note that the work obtained from the above reaction in the electric cell is about 69.9 kcal, while the heat obtained from the direct combination is about 75.2 kcal. The question might be asked: Can we carry out the process in such a way that all the heat liberated in the direct combination is converted into work? If this were possible no heat would be given to the surroundings, and hence they would undergo no change of entropy. This would make the total entropy change  $0 + (-17.0) = -17.0$ , which, according to our rule, is impossible. In this instance our argument is circular, because we obtained the figure for the entropy change from the assumption that the work associated with an electromotive force of 1.516 volts is the reversible work. Nevertheless our rule that the total entropy change must be zero or positive is a convenient way of summarizing our ability to predict the behaviour of a system. In general, if we know the entropy change for each step in a process or set of linked processes we can, in a manner similar to the above, determine whether the process is possible or not; although, if it is possible, thermodynamics tells nothing about its rate—a determination which lies in the province of chemical, or reaction, kinetics (see CHEMISTRY: Chemical Kinetics; REACTION KINETICS).

Since the entropy of a system is a function of temperature, volume, and pressure, it would be quite impractical to try to measure the entropy of systems at all desired combinations of these variables; even if obtainable, it would be troublesome to tabulate them. To make a smaller number of measurements sufficient for most purposes we need to know how the entropy of a system changes with change of temperature, volume, or pressure. If a system is in equilibrium with surroundings at  $T$  and  $P$ , and its volume is changed reversibly and isothermally, the work done is  $PdV$  for an infinitesimal change of volume, and the heat absorbed is  $dE + PdV$ . Since the entropy change is the reversible heat absorbed divided by the temperature,  $TdS = dE + PdV$ . Formally dividing by  $dV$ , and noting that  $T$  is constant,

$$T(dS/dV)_T = (dE/dV)_T + P \quad (7)$$

If a system is heated reversibly at constant volume, the heat absorbed, for an infinitesimal change, is  $C_v dT$ , and  $dS = C_v dT/T$ . Dividing by  $dT$ , we obtain

$$(dS/dT)_v = C_v/T \quad (8)$$

Differentiating (7) with respect to  $T$ , and (8) with respect to  $V$ , and combining, we obtain

$$(dS/dV)_T = (dP/dT)_v \quad (9)$$

Equations (7), (8), and (9) are relevant to changes taking place at constant volume, or when temperature and volume are chosen as the independent variables, but processes are more likely to be carried out at constant pressure, or to be considered in terms

of temperature and pressure. If to the right side of the equation  $TdS = dE + PdV$ , we add  $d(PV)$  and subtract its equivalent  $PdV + VdP$ , we obtain  $TdS = d(E + PV) - VdP$ . Defining the enthalpy, or heat content, as

$$H = E + PV \quad (10)$$

we can then obtain

$$T(dS/dP)_T = (dH/dP)_T - V \quad (11)$$

Also, for reversible heating at constant pressure,

$$(dS/dT)_p = C_p/T \quad (12)$$

From (11) and (12), noting that  $C_p = (dH/dT)_p$ ,

$$(dS/dP)_T = -(dV/dT)_p \quad (13)$$

Since  $dS = (dS/dV)_T dV + (dS/dT)_p dT$  or  $dS = (dS/dP)_T dP + (dS/dT)_p dT$ , the most generally useful of the above equations are the pairs (8) and (9) and (12) and (13).

Equations (8) and (12) have the same form, and one can be obtained from the other by interchanging  $P$  and  $V$ . Equations (9) and (13) form a similar pair, except for the change of sign. The pair (7) and (11) follow a similar pattern if, in addition to a change of sign, we interchange  $E$  and  $H$ . When thermodynamic relationships are expressed in terms appropriate to choosing temperature and volume as the independent variables, comparatively simple equations are obtained, but when temperature and pressure are chosen, this simplicity is lost unless  $E$  is expressed in terms of  $H$ . For a process occurring at constant volume, doing no work, the heat absorbed,  $q = \Delta E$ , but if a process occurs at constant pressure, doing no work except that due to the expansion (or contraction) of the system against the constant pressure,  $q = \Delta E + P\Delta V = \Delta H$ . Tables of heats of fusion, of vaporization, and of reaction commonly give the heat absorbed at constant pressure, and accordingly  $\Delta H$  for the process. It may be anticipated that the Helmholtz free energy and the Gibbs function,  $A$  and  $G$  respectively, introduced in section 7, relate naturally to the temperature-volume and the temperature-pressure systems, respectively.

**6. The Clapeyron Equation.**—The change of vapour pressure of a liquid can be derived from equation (12). If vaporization of a liquid is allowed to take place while liquid and vapour are in equilibrium at constant temperature  $T$ , the latent heat of vaporization,  $\Delta H_{\text{vap}}$ , is absorbed while the system undergoes the volume change  $\Delta V$ . The entropy change per unit change of volume is then

$$\Delta H_{\text{vap}}/T\Delta V = (\Delta S/\Delta V)_T = (dS/dV)_T = (dP/dT)_v = dP/dT \quad (14)$$

for equilibrium between the phases.  $\Delta H_{\text{vap}}/T$  is the entropy change, since  $\Delta H_{\text{vap}}$  is the heat absorbed when the change takes place reversibly, and  $(\Delta S/\Delta V)_T$  is equal to  $(dS/dV)_T$  since  $\Delta S/\Delta V$  is independent of the amount of transformation which has occurred. This, by equation (12), is equal to  $(dP/dT)_v$ , but the restriction of constant volume is unnecessary since the change of pressure with change of temperature is the same whether volume is constant or not, as long as pure liquid and gas are in equilibrium.

The same form of equation applies to any equilibrium transition in which the number of phases is sufficient to keep the composition of each phase constant during the isothermal change. Thus, at the transition point of sodium sulfate,  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O} \rightarrow 0.37 \text{ Na}_2\text{SO}_4 + 269.5 \text{ g solution}$ , the latent heat of transition  $L = 17.3$  kcal and  $\Delta V = 1.3$  cc. Converting the heat in calories to  $\text{cm}^3\text{-atm}$  and using (14), we find that the transition temperature changes  $0.00055^\circ \text{C}$  per atm change of pressure.

**7. The Gibbs Function.**—An important use of thermodynamic data is in predicting whether a process will occur spontaneously—and further: if spontaneous, how much work could be obtained from the process if it were carried out reversibly; if not spontaneous, what is the minimum work required to carry out the process. A consideration of the entropy changes of all subsystems of interest, including the entropy changes of the surroundings, is sufficient for this purpose. However, in most cases the processes under consideration are at constant temperature and in communication with

surroundings at the same temperature, and also are usually at constant pressure. In such cases two auxiliary functions, the Helmholtz free energy,

$$A = E - TS \text{ (definition)} \quad (15)$$

and the Gibbs function, sometimes called the free energy or the free enthalpy,

$$G = H - TS \text{ (definition)} \quad (16)$$

are of great value. (Some authors have denoted  $E - TS$  and  $H - TS$  by  $A$  and  $F$ , while others have used  $F$  and  $G$ . This use of  $F$  for both functions has practically destroyed its utility, and is here avoided for that reason.) The Gibbs function, embodying one of the most important concepts in thermodynamics, was formulated by J. Willard Gibbs (*q.v.*; 1839–1903), who was chiefly responsible for the extension of thermodynamics into chemistry.

It can be shown that for an isothermal reversible process the work done is the initial value of  $A$  minus its final value, or  $-\Delta A$ . In a reversible process occurring at constant temperature and pressure, part of the work is done in expanding the system against the pressure of its surroundings, and the net work,  $w'$ , is  $-\Delta G$ . If the process is not reversible, the net work is less. In general, for any process at constant temperature and pressure

$$w' \leq -\Delta G \quad (17)$$

If  $\Delta G$  is negative the process is spontaneous; if zero the system is in equilibrium; and if positive the process can be made to take place only by doing work on the system or by linking it with another system undergoing a process with negative  $\Delta G$ . (In the latter case, if the two systems are considered as one, the total  $\Delta G$  for the combined system must then be negative or zero.)

Here, as with entropy, little use can be made of these functions unless we can obtain their changes with temperature and volume or with temperature and pressure, respectively. Using the definitions of  $A$  and  $G$  above, and the previously obtained relations for  $S$ , we readily obtain

$$(dA/dT)_v = -S \quad (18)$$

$$(dA/dV)_T = -P \quad (19)$$

$$(dG/dT)_p = -S \quad (20)$$

and

$$(dG/dP)_T = V \quad (21)$$

On replacing the entropy in the above relations by  $(E - A)/T$  and  $(H - G)/T$  respectively, we obtain from (18) and (20)

$$(d(A/T)/dT)_v = -E/T^2 \quad (22)$$

and

$$(d(G/T)/dT)_p = -H/T^2 \quad (23)$$

With compilations of  $G$ ,  $H$ , and  $C_p = (dH/dT)_p$  for large numbers of substances at arbitrarily chosen standard conditions (usually 25° C and 1 atm) and the above relations for the change with temperature and with pressure, the Gibbs energy changes of a very great number of processes occurring at constant temperature and pressure can be calculated. From these calculations it can be determined whether the process is spontaneous or not. Since energy can be measured only relative to an arbitrarily chosen base, this is likewise true of  $H$ ,  $A$ , or  $G$ ; tables of these quantities are given relative to the values for the elements composing the substances, in that state in which they ordinarily occur at 25° C and 1 atm.

**8. Chemical Potential.**—The relations thus far developed are sufficient for thermodynamic treatment of systems in which each substance occurs only in the pure state. However, in many cases one is interested in systems in which solutions occur. (In this and following sections the reader may have frequent occasion to consult the article SOLUTIONS on matters of detail or of parallel interest.)

Consider, for example, the vapour pressure of a 25% aqueous potassium chloride solution, and its change with temperature. The amount of KCl in the vapour is far too small to be detectable, and we may consider the vapour to be pure water. One method for measuring the vapour pressure of pure water is to put it into a previously evacuated space, allow water to evaporate into it until

it is saturated, and measure the pressure of the vapour with a manometer.

If the same method is used for the salt solution, its composition will change during the evaporation. To obtain the result we desire we must either make the amount of salt solution very large relative to the amount of water evaporated or put the solution in contact with a vapour space which is already nearly saturated with the vapour. In either case the process of interest may be described by the balanced "chemical equation"  $\Delta n_1 \text{H}_2\text{O}$  (25% KCl solution) =  $\Delta n_1 \text{H}_2\text{O}$  (gas) where  $n_1$  is the number of moles of water. If a nearly saturated space is used,  $\Delta n_1$  is very small and the solution is not appreciably changed during evaporation. If a large amount of solution is used  $\Delta n_1$  may be much larger without appreciable change of composition.

For convenience we may write the reaction for the evaporation of one mole of water as  $\text{H}_2\text{O}$  (25% solution) =  $\text{H}_2\text{O}$  (gas). The corresponding change of the Gibbs function is  $\Delta G = G(\text{gas}) - (dG/dn_1)_{n_2, P, T}$  where  $n_1$  and  $n_2$  are respectively the number

of moles of water and of salt in the solution, and  $(dG/dn_1)_{n_2, P, T}$  is the limit of the change of the Gibbs function of the solution on addition of water, divided by the amount added, as the addition approaches zero. (The subscripts indicate that during the addition of water the temperature, pressure, and amount of salt are kept constant.)

For solutions containing three or more components the amounts of all but one must be kept constant. When misunderstanding seems unlikely, some or all such subscripts will be omitted. The quantity  $(dG/dn_i)_{P, T}$  is called the chemical potential of substance  $i$  in the solution, and is generally written  $\mu_i$ , sometimes  $\bar{G}_i$ . While we have introduced the chemical potential as  $(dG/dn_i)_{P, T}$ , it can be shown that  $\mu_i$  is also equal to  $(dA/dn_i)_{V, T} = (dE/dn_i)_{S, V} = (dH/dn_i)_{S, P}$ . Since, however,  $\mu_i$  is generally employed in connection with processes at constant temperature and pressure, its expression  $(dG/dn_i)_{P, T}$ , for correlation with  $G$ , is most frequently encountered. Gibbs originally expressed  $\mu$  on a weight basis, but for chemical use it is more conveniently given, as above, on a molal basis.

The use of the chemical potential at various temperatures and pressures requires its change with temperature and pressure. By performing the appropriate partial differentiations we readily obtain

$$(d\mu_i/dT)_P = -(dS/dn_i)_{T, P} = -\bar{S}_i \quad (24)$$

$$(d\mu_i/T)/dT)_P = -\bar{H}_i/T^2 \quad (25)$$

$$(d\mu_i/dP)_T = (dV/dn_i)_{T, P} = \bar{V}_i \quad (26)$$

where, according to a common convention, the derivative with respect to  $n_i$ , keeping  $T$ ,  $P$ , and the quantities of other constituents constant, is called the partial molal quantity, and is abbreviated as above, with a bar over the symbol, together with the subscript.

Numerical values of  $\mu$  are obtained from reactions involving the appropriate substance in its solution and in the pure state, for which the change of  $G$  either is known or can be measured. If the system is in equilibrium,  $\mu_i$  is the same in each phase containing the constituent. (See PHASE EQUILIBRIA.) In the above example of an aqueous KCl solution,  $\mu_{\text{H}_2\text{O}}$  (solution) =  $\mu_{\text{H}_2\text{O}}$  (gas) =  $G_{\text{H}_2\text{O}}$  (gas at vapour pressure of the solution). If we assume that the vapour obeys the gas law, from  $(dG/dP)_T = V = RT/P$  we obtain  $\mu_{\text{H}_2\text{O}}$  (solution) =  $G_{\text{H}_2\text{O}}$  (pure liquid) +  $RT \ln P_s/P_w$ , where  $P_s$  and  $P_w$  are the vapour pressures of solution and of pure water respectively. To obtain the chemical potential of the KCl in the solution we note that the 25% solution is saturated at 17.8° C, and  $\mu_2(\text{solution}) = \mu_2(\text{solid}) = G_2(\text{solid})$ . If the chemical potential in the solution is desired at some other temperature, by using equation (25) we obtain

$$\mu(T') = G(\text{solid}, T') - T' \int_{T_s}^{T'} (\bar{H} - H_s) dT/T^2$$

where  $T_s$  is the saturation temperature and  $\bar{H} - H_s$  is the heat absorbed when one mole of solid KCl is dissolved in a quantity of nearly 25% KCl solution sufficient to make the change of composition negligible.

9. **Activity.**—For an ideal gas,

$$\mu'' - \mu' = \int V dP = \int RT dP/P = RT \ln P''/P' \quad (27)$$

Since most gases at moderate or low pressures deviate only slightly from ideality, it is convenient to define the activity,  $a$ , of the gas (also called its fugacity, as here defined) by the equation

$$RT \ln a''/a' = \mu'' - \mu' = \int V dP \quad (28)$$

Subtracting  $RT \ln P''/P'$  from the left, and its equal,  $\int_{P'}^{P''} RT dP/P$ ,

from the right, we obtain  $RT \ln (a''/P'')/(a'/P') = \int_{P'}^{P''} (V - RT/P) dP$  where  $V - RT/P$  is the deviation of the volume of the gas from ideality. A numerical scale for the activity of a gas can now be conveniently established by making  $a'/P'$  approach unity as  $P'$  approaches zero, leading to

$$RT \ln a''/P'' = \int_0^{P''} (V - RT/P) dP \quad (29)$$

As  $P$  approaches zero, both  $V$  and  $RT/P$  become infinite. However, both theory and experiment indicate that the difference approaches a finite value as the pressure approaches zero, and hence the integral of (29) can be evaluated.

As the total pressure of a gaseous mixture approaches zero each constituent is progressively less affected by the others, and it is consistent to define the activity of a gaseous constituent such that, as the pressure approaches zero,  $a_i/PN_i = 1$ , where  $N_i$  is the mole fraction of constituent  $i$  in the mixture. For a mixture, equation

(28) becomes  $RT \ln a''/a' = \int_{P'}^{P''} \bar{V}_i dP$  where  $\bar{V}_i$  is the change of volume of the mixture upon addition of one mole of constituent  $i$ , when the pressure and temperature and the amount of all other constituents are kept constant, and the total quantity is so large that the change of composition is negligible. Subtracting  $\int_{P'}^{P''} dP/P$  from each side and letting  $P'$  approach zero, we obtain

$$RT \ln a''/P''N_i = \int_0^{P''} (\bar{V}_i - RT/P) dP \quad (30)$$

From the relation of the activity to the chemical potential it is clear that the activity of a liquid or a solid is equal to the activity of its saturated vapour, if the activity is measured on the scale adopted for gases. For substances of very low volatility this scale is impractical; even for readily volatile ones it is frequently convenient to adopt different scales or bases of activity. Including the one just given, there are four commonly used bases:

Base 1, for a pure gas,  $a/P = 1$  as  $P = 0$ , and for a gaseous mixture  $a_i/PN_i = 1$  as  $P = 0$ .

Base 2, for a substance in solid or liquid solution, especially when considered as a solvent,  $a = 1$  for the pure solid or liquid at 1 atm pressure.

Base 3, for a substance in solution particularly when considered as a solute,  $a/N = 1$  as  $N = 0$ .

Base 4, for solutes for which the concentration is expressed in molality,  $m$ , the number of moles of solute per kilogram of solvent,  $a/m = 1$  as  $m = 0$ .

Care must be exercised in the use of activity when a base other than 1 is used: for two phases in equilibrium the activity of a constituent in phase A is equal to that in phase B if base 1 is used in both, but if base 1 is used for phase A and a different base is used for phase B the activities at equilibrium will now not be equal. If base 2 is used for both phases the activities are again equal at equilibrium, but with the use of base 3 or 4 the activity is not the same in the two phases in equilibrium, even when the same formal base is used for both, since the solvents are not identical.

Many solutions, particularly those of substances which are quite similar, conform rather closely to the relations  $a_1 = a_1^\circ N_1$  and  $a_2 = a_2^\circ N_2$  where  $a^\circ$  is the activity of the pure substance in the same physical state as the solution. Solutions which satisfy these relations exactly are called ideal. If it be required that the relations are satisfied at all temperatures and pressures, there must also be neither heat effects nor volume changes on mixing

the constituents. Such stringent requirements are not exactly satisfied even by mixtures of isotopes, but for moderate ranges of pressure and temperature a surprisingly large number of pairs of substances conform quite closely. In such cases the activity divided by the mole fraction, called the activity coefficient, is nearly unity over the whole range of compositions, and its deviation from unity is a measure of the deviation from ideality. If the solution is ideal over the whole range, the activity on base 3 is identical with that on base 2, but otherwise they will be different. Activity coefficients are defined as  $a/N$  for bases 2 and 3; for 1 and 4 they are  $a/PN$  and  $a/m$  respectively. Various symbols have been used for the different activity coefficients;  $\gamma$  has been most commonly used for  $a/m$ , and will be used here for any activity coefficient, since the context will usually make clear which one is meant.

#### 10. Change of Activity with Temperature and Pressure.

—Consider the transfer of one mole of a constituent from one solution to another, when the quantity of each is so large that no appreciable change of composition occurs as a consequence of the transfer. For this transfer,  $\mu - \mu' = RT \ln a/a'$  where  $\mu$ ,  $\mu'$  and  $a$ ,  $a'$  are respectively the chemical potential and the activity of the constituent in the two solutions. Using equation (25), and writing  $a' = \gamma'x'$  where  $x'$  may be  $P'N'$ ,  $N'$ , or  $m'$  according to which defining base is used, we obtain

$$(d \ln a/dT)_P = d \ln \gamma'/dT + d \ln x'/dT - (\bar{H} - \bar{H}')/RT^2 \quad (31)$$

For arbitrary compositions of the primed phase, (31) will have slight usefulness because of ignorance concerning the change of  $\gamma'$  with temperature. But if we choose  $x'$  such that  $\gamma'$  is very nearly unity at both  $T$  and  $T + dT$ , we may make the first term on the right of (31) as small as we please; and by choosing  $x'$  independent of temperature, the second term is zero. From this we obtain

$$(d \ln a/dT)_P = -(\bar{H} - \bar{H}^\circ)/RT^2 \quad (32)$$

where  $\bar{H}^\circ$  is the limit of  $\bar{H}$  as the composition is changed so that  $\gamma'$  approaches unity, and  $\bar{H} - \bar{H}^\circ$  is the limit of the heat absorbed when a mole of the constituent is transferred from a chosen solution to one whose composition is such as to make its activity coefficient approach unity. For convenience we may refer to this state as the defining state. For base 1 it is gaseous solution as the total pressure approaches zero, for base 2 it is the pure substance at standard pressure (generally 1 atm), and for bases 3 and 4 it is the substance in dilute solution as its concentration approaches zero.

From the definitions of the activity we easily obtain

$$(d \ln a/dP)_{T,N} = \bar{V}/RT \quad (33)$$

for each of the four bases which have been given for defining the activity. The subscript  $N$  denotes that the composition is kept constant.

#### 11. The Gibbs-Duhem and Duhem-Margules Equations.

—When a system is formed by the combination of two or more identical subsystems without changing the properties of the subsystems, we define as intensive properties those which are the same for the total system as for the subsystems, and as extensive properties those which are greater for the total system than for any one of the subsystems, in proportion to the ratio of their masses.

Temperature, density, and refractive index are common intensive properties; volume, energy, entropy, and the Gibbs function are representative of extensive properties. Using volume as an example, we may write (for a binary mixture; the results may be readily generalized)  $dV = (dV/dn_1)dn_1 + (dV/dn_2)dn_2 = \bar{V}_1dn_1 + \bar{V}_2dn_2$  where the derivatives are taken keeping  $T$ ,  $P$ , and the quantity of other constituents constant. The partial molal volumes,  $\bar{V}_1$  and  $\bar{V}_2$ , are functions of composition but not of the total mass of the system, and are intensive quantities. From this fact, and from the definitions of the quantities, simple mathematical manipulations yield  $V = n_1\bar{V}_1 + n_2\bar{V}_2$  and  $n_1d\bar{V}_1 + n_2d\bar{V}_2 = 0$ . Corresponding relations may be obtained from the

partial molal quantities derived from any extensive property. Using the Gibbs function we find

$$n_1 d\bar{G}_1 + n_2 d\bar{G}_2 = 0; \text{ or, using } \mu_i = \bar{G}_i, n_1 d\mu_1 + n_2 d\mu_2 = 0 \quad (34)$$

From the definition of activity we obtain from equation (34)  $n_1 d \ln a_1 + n_2 d \ln a_2 = 0$ , and dividing by  $n_1 + n_2$ ,

$$N_1 d \ln a_1 + N_2 d \ln a_2 = 0 \quad (35)$$

Since  $N_1 + N_2 = 1$ ,  $dN_1 + dN_2 = 0$ , and hence  $N_1 d \ln N_1 + N_2 d \ln N_2 = 0$ , we also find  $N_1 d \ln \gamma_1 + N_2 d \ln \gamma_2 = 0$  for all expressions of the activity coefficient except that on a molality basis.

Equations (34) and (35) are known respectively as the Gibbs-Duhem equation and the Duhem-Margules equation. They were both first obtained by Gibbs, and are so closely related that it seems hardly worth making a distinction between them. If we assume that the vapours of the constituents obey the gas law, on replacing activities by partial pressures we obtain the approximate equation  $N_1 d \ln P_1 + N_2 d \ln P_2 = 0$ , which gives in principle a means of finding the vapour pressure of one constituent of a solution if it is known at one composition and if the vapour pressure of the other is known over the entire range; but in practice the vapour pressures of the second must be known with rather high precision to get fairly good values of the first.

**12. Dilute Solutions; Henry's Law.**—In a very dilute solution, a solute molecule will (with rare exceptions) have only solvent molecules as near neighbours, and the probability of escape of a particular solute molecule into the gas phase is expected to be independent of the total concentration of solute molecules. In this case the rate of escape of solute molecules will be proportional to their concentration in the solution, and solute will accumulate in the gas until the return rate is equal to the rate of escape. With a very dilute gas this return rate will be proportional to the partial pressure of solute. Thus we expect that, for a solution very dilute in solute, in equilibrium with a gas at very low pressure,  $P_2 = k'N_2$ —the relation known as Henry's law. Since for gases at very low pressure the activity is proportional to the partial pressure, we may also write

$$a_2 = k'N_2 \quad (36)$$

which is the thermodynamically convenient form of Henry's law. While the above argument is to be considered only suggestive, Henry's law is found experimentally to hold for all dilute solutions in which the molecular species is the same in the solution as in the gas. The most conspicuous apparent exception is the class of electrolytic solutions, which will be discussed separately.

**13. Raoult's Law.**—Substituting (36) in (35) and using, for the binary solution,  $dN_1 + dN_2 = 0$ , we readily obtain  $a_1 = k''N_1$ , and substituting  $a_1 = a_1^\circ$  when  $N_1 = 1$ , we find

$$a_1 = a_1^\circ N_1 \quad (37)$$

where  $N_1$  is the mole fraction of the solvent in a solution which is very dilute in solute. This relation is generally known as Raoult's law, although originally expressed as  $P_1 = P_1^\circ N_1$ . It has frequently been used to find the molar weight of nonvolatile solutes by transforming to  $M_2 = M_1 P_1 w_2 / (P_1^\circ - P_1) w_1$ , where  $w_1, w_2, M_1, M_2$  are the weights of solvent and solute in the solution, and the molar weights, respectively.

**14. Freezing Point Lowering.**—At the freezing point of pure liquid,  $T_0$ ,  $\mu_1$  (liquid) =  $\mu_1$  (solid). Using equation (25) and neglecting the change of the heat of fusion with temperature, we obtain, at  $T$ ,

$$\mu_1 \text{ (solid)} - \mu_1 \text{ (liquid)} / T = \Delta H_{\text{fusion}} (1/T_0 - 1/T) \quad (38)$$

where  $\mu_1$  (liquid) is here the chemical potential of the pure supercooled liquid. From the definition of activity (28), and from Raoult's law (37)

$$\mu_1 \text{ (solution)} / T = \mu_1 \text{ (liquid)} / T + R \ln N_1 \quad (39)$$

and if  $T$  is the freezing point of the solution, or the temperature at which the solution is in equilibrium with solid solvent,

$$\mu_1 \text{ (solid)} = \mu_1 \text{ (solution)} \quad (40)$$

Combining (38), (39), and (40), we obtain

$$R \ln N_1 = \Delta H_{\text{fusion}} (1/T_0 - 1/T) \quad (41)$$

While equation (41) has been obtained for the dilute solution, for which Raoult's law holds, it is also valid for the ideal solution over the whole range, except that the neglect of the change of heat of fusion with temperature may now introduce error if the lowering is large. Also, (41) is valid only if the solvent separates as the pure solid; if solid solution is formed, (41) must be replaced by

$$R \ln (N_1/N_1') = \Delta H_{\text{fusion}} (1/T_0 - 1/T) \quad (42)$$

where  $N_1'$  is the mole fraction of solvent in the solid solution.

For dilute solutions ( $N_2$  small), equation (41) can be transformed into the approximate form  $T_0 - T = (RT_0^2/\Delta H_{\text{fusion}})(N_2)$ . The freezing point lowering, the lowering of vapour pressure, and the elevation of the boiling point are employed for estimating the molal weight of a solute.

**15. Boiling Point Elevation.**—If the solute is nonvolatile the elevation of the boiling point can be obtained by steps which are analogous to those used in deriving the lowering of the freezing point. The result is  $R \ln N_1 = \Delta H_{\text{vap}} (1/T - 1/T_0)$  or  $\Delta T \cong (RT_0^2/\Delta H_{\text{vap}})N_2$ , where  $T_0$  is the boiling point of the pure solvent,  $T$  is that of the solution,  $\Delta T$  is  $T - T_0$ , and  $\Delta H_{\text{vap}}$  is the heat of vaporization of the solvent. If the solute is also volatile an equation analogous to (42) is obtained:  $R \ln N_1/N_1'' = \Delta H_{\text{vap}} (1/T - 1/T_0)$ , where  $N_1''$  is the mole fraction of the solvent in the vapour.

**16. Osmotic Pressure.**—If a solution and pure solvent are separated by a membrane which permits passage of solvent only, the solvent will pass from its pure state to the solution unless a difference in pressure is maintained between them, because the activity of the solvent is less in the solution than in the pure solvent. For equilibrium the change of activity with composition must be offset by the change with pressure, or  $(d \ln a_1/dN_1)_P dN_1 + (d \ln a_1/dP)_N dP = 0$ . Substituting equations (37) and (33) we find

$$dP/dN_2 = -dP/dN_1 = RT/N_1 \bar{V}_1 \quad (43)$$

For very dilute solutions the partial molal volume,  $\bar{V}_1$ , approaches  $V_1$ ; the mole fraction of pure solvent,  $N_1$ , is nearly 1; and  $P - P^\circ \cong N_2 RT/V_1 \cong n_2 RT/V$  where  $n_2$  is the number of moles of solute in solution of volume  $V$ ,  $P^\circ$  is the pressure on the pure solvent, and  $P$  is the pressure on the solution when no flow of solvent can occur through the membrane. The right-hand term is the form used by J. H. van't Hoff. Because of its similarity to the ideal gas law it was at one time made the base for the derivation of the properties of dilute solutions, but Henry's law seems a simpler and more fundamental one to use.

**17. Solutions of Electrolytes.**—For dilute solutions, in which the solute molecules are surrounded only by solvent molecules, it seems a valid assumption that the vapour pressure of the solute should be proportional to its concentration, as expressed by Henry's law. The outstanding exception to this relation is the class of solutes known as electrolytes (those which conduct electric current, concomitant to their dissociation into ions). Hydrogen chloride in the gaseous state exists as HCl molecules, but in dilute aqueous solution it occurs almost entirely as the (presumably hydrated) hydrogen ions and chloride ions,  $H^+$  and  $Cl^-$ . Because of the high dielectric constant of water the attraction of the unlike charges is greatly reduced, and in very dilute solution the ions behave nearly as if the others were not present. There is no satisfactory way of determining the concentration of neutral HCl molecules in aqueous solution, but if we assume that in dilute solution the activity of each ion is proportional to its concentration, we can predict that the activity of HCl, and likewise its partial pressure, should be proportional to the square of the stoichiometric concentration. This is indeed the case, and we conclude that the failure to obey Henry's law is more apparent than real. All strong electrolytes behave as if the ions in dilute solution obey Henry's law, and hence the activity of the electrolyte varies as the square, cube, . . . of the electrolyte concentration,

according as the electrolyte dissociates into two, three, . . . ions. If base 4 is used for the definition of the activity of ions, the activity coefficient of the ion approaches unity as the concentration approaches zero. Because of the long range of the effects of the electrostatic forces of ions upon one another, however, the activity coefficients of ions deviate appreciably from unity even in very dilute solutions. When the solutions are so dilute that their interactions are almost entirely due to their charges, the activity coefficient can be calculated quite satisfactorily by the method of P. Debye and E. Hückel, which correlates the electrostatic interaction of an ion with the average distribution of ions around it, assuming that this distribution of ions is determined by the potential which would result from such an average distribution. Such calculations appear to give the activity coefficients of individual ions. However, because of the maintenance of approximate electrical neutrality, individual ion activities or activity coefficients cannot in fact be measured; only products of activity coefficients of ions of unlike charges, or quotients of ions of like charges, can be obtained. For example, one might measure the distribution of  $\text{FeCl}_3$  between an organic solvent and an aqueous solution of  $\text{FeCl}_3$  and  $\text{HCl}$ , and also measure the partial pressure of  $\text{HCl}$  in equilibrium with the solution. If the measurements are carried out on a series of solutions to sufficiently great dilution, one could obtain  $\gamma_{\text{H}^+} \gamma_{\text{Cl}^-}$  and  $\gamma_{\text{Fe}^{3+}} \gamma_{\text{Cl}^-}$ . One can also obtain  $\gamma_{\text{Fe}^{3+}}/\gamma_{\text{H}^+}$ ,  $\gamma_{\text{Fe}^{3+}} \gamma_{\text{Cl}^-}/\gamma_{\text{H}^+}$ , or any other combination obtained by multiplying or dividing the first two products.

In spite of our inability to measure the thermodynamic properties of individual ions, tabulations of free energies and entropies of formation, and activity coefficients of ions can be found. The entries in such tables are convenient fictions dependent on arbitrary assignments of activity coefficients to some ion, and are useful only when combined with other values based on the same convention so that the net result corresponds to a system with no net charge, or to a process with no change of charge. For the above system, entries from such tables would be appropriate for reactions such as  $\text{H}^+ + \text{Cl}^- = \text{HCl}$  (gas),  $\text{Fe}^{3+} + 3\text{Cl}^- = \text{FeCl}_3$  (gaseous, or in some appropriate solution),  $\text{Fe}^{3+} + \frac{3}{2}\text{H}_2 = \text{Fe} + 3\text{H}^+$ , etc. In the system considered above, the activity of  $\text{HCl}$  is proportional to the product of the activity of hydrogen ion and of chloride ion, and the activity of  $\text{FeCl}_3$  is proportional to the activity of ferric ion times the cube of that of the chloride ion. It is convenient to define the base of activity of the strong electrolytes such that the activity of the electrolyte is equal to the product of the appropriate ion activities. Since the individual ion activities cannot be determined, this appears to be a questionable procedure, but it is just these combinations of ion activities which can be measured. The above convention is regularly used for strong electrolytes or for those usually considered to be almost completely dissociated. For weak electrolytes or those of an intermediate degree of dissociation, activities and activity coefficients are usually based on the concentrations assumed to exist in the solution, rather than on the stoichiometric concentrations.

**18. The Electromotive Force of Galvanic Cells.**—Measurements of activities of strong electrolytes are made in many cases by the same methods which are used for nonelectrolytes; e.g., by equilibrium with another phase containing the electrolyte or by freezing point depression combined with the use of the Gibbs-Duhem relation (35). The activity is also frequently obtained from the electromotive force of a reversible cell which involves the production or consumption of the electrolyte. If the reversible electromotive force of the cell is  $\mathcal{E}$ , then

$$\Delta G = -n\mathcal{F}\mathcal{E} \quad (44)$$

where  $\mathcal{F}$  is the value of the faraday in appropriate units,  $\Delta G$  is the change of the Gibbs function for the change which occurs in the cell with passage of electricity, and  $n$  is the number of faradays which correspond to the chemical reaction written for the process. For example, when current is passed through the cell containing aqueous  $\text{HCl}$ , with a platinum anode surrounded by gaseous  $\text{H}_2$  and a silver cathode in contact with solid  $\text{AgCl}$ ,  $\text{HCl}$  is produced according to the reaction

For the specified amount of reaction, one faraday would be required, and  $n$  of equation (44) is 1. Subtracting the results of two cells differing only in the concentrations of  $\text{HCl}$ , we obtain  $\text{HCl}(m') = \text{HCl}(m'')$ ;  $\Delta G = n\mathcal{F}(\mathcal{E}' - \mathcal{E}'') = RT \ln a_2''/a_2'$  where  $a_2'$  and  $a_2''$  are the activities of  $\text{HCl}$  in the two solutions. For dilute solutions the activity of  $\text{HCl}$  is proportional to the square of the concentration, and the geometric mean activity and activity coefficient are defined by  $a_{\pm}^2 = a_{\pm} = \gamma_{\pm} m_{\pm}$  where  $m_{\pm}$  is the geometric mean of the molalities of  $\text{H}^+$  and  $\text{Cl}^-$ . The molalities of the ions of strong electrolytes are calculated as if they are completely ionized. Accordingly, for pure aqueous  $\text{HCl}$ ,  $m_{\pm} = m$  where  $m$  is the total number of moles of  $\text{HCl}$  per kilogram of water. (For a more complex electrolyte, a weighted geometric mean is used; e.g., for  $\text{BaCl}_2$ ,  $a_{\pm} = a_{\text{BaCl}_2}^{\frac{1}{3}} = \gamma_{\pm} m_{\pm}$  where  $m_{\pm} = [m_{\text{Ba}} + m_{\text{Cl}}^2]^{\frac{1}{3}}$ ). The  $a_{\pm}$  and  $\gamma_{\pm}$  so defined are convenient because, like the  $a$  and  $\gamma$  of nonelectrolytes,  $a_{\pm}$  approaches the concentration and  $\gamma_{\pm}$  approaches unity as the concentration approaches zero. The activity coefficients of strong electrolytes reported in the literature are almost universally the  $\gamma_{\pm}$  as defined above.

**19. The Equilibrium Constant.**—From the definition of activity we have  $\Delta G = \mu - \mu' = RT \ln a/a'$  for the transfer of a substance from a system in which its activity is  $a'$  to a system in which it is  $a$ , when the same base of activity is used in both. We may rewrite this

$$\mu - \mu' = \bar{G} - \bar{G}' = RT \ln a \quad (45)$$

writing  $\mu' = \bar{G}'$  for the chemical potential for the state in which  $a' = 1$ . Consider the isothermal reaction  $lL + l'L' + \dots = rR + r'R' + \dots$  for which

$$\Delta G = (rG_R + r'G_{R'} + \dots) - (lG_L + l'G_{L'} + \dots) = (rG_R^{\circ} + r'G_{R'}^{\circ} + \dots) - (lG_L^{\circ} + l'G_{L'}^{\circ} + \dots) + RT \ln J = \Delta G^{\circ} + RT \ln J \quad (46)$$

in which  $J$  is  $(a_R^r a_{R'}^{r'} \dots) / (a_L^l a_{L'}^{l'} \dots)$  by definition. We may call  $J$  the activity quotient, which, with arbitrary values of the component activities, can have any positive value.

Now let us consider the same reaction with the system in equilibrium. In this case

$$\Delta G = 0 = \Delta G^{\circ} + RT \ln J_e = \Delta G^{\circ} + RT \ln K, \text{ or } RT \ln K = -\Delta G^{\circ} \quad (47)$$

where  $K$ , the equilibrium constant, is equal to  $J_e$ , the value of the activity quotient for the system in equilibrium. Let us write  $K = Q_x Q_{\gamma}$  where  $Q_x$  and  $Q_{\gamma}$  are quotients of the same form as  $K$ , but with  $x$  and  $\gamma$  substituted for  $a$ . As in equation (31),  $x$  is used for  $PN$ ,  $N$ , or  $m$  according to the base used for the definition of the activity, which may vary within a quotient  $Q_x$ . While  $K$  is constant at constant temperature,  $Q_x$  and  $Q_{\gamma}$  will generally vary with change of composition. However, if each substance is nearly in its defining state, each  $\gamma$  will be nearly 1,  $Q_{\gamma} \cong 1$ , and  $K \cong Q_x$ .

As an example, consider the precipitation of  $\text{CoS}$  by the action of  $\text{H}_2\text{S}$  on a dilute solution of  $\text{CoCl}_2$  at  $25^{\circ}\text{C}$ . If the solution is very dilute we may assume the  $\text{HCl}$  which is produced, and the  $\text{CoCl}_2$  which remains, to be completely ionized, and write the reaction  $\text{Co}^{2+} + \text{H}_2\text{S}(\text{gas}) = \text{CoS}(\text{solid}) + 2\text{H}^+$  omitting the chloride ions since they undergo no appreciable change. From suitable compilations of thermodynamic data we find  $\Delta G^{\circ}$  for the above reaction is  $-1.2$  kcal, from which

$$K = Q_{\gamma} \cdot Q_x = Q_{\gamma} (m_{\text{H}^+})^2 / P_{\text{H}_2\text{S}} \cdot m_{\text{Co}^{2+}} = 7.6, \text{ or } m_{\text{Co}^{2+}} = Q_{\gamma} (m_{\text{H}^+})^2 / 7.6 P_{\text{H}_2\text{S}}$$

The activity coefficient of pure solid  $\text{CoS}$  is 1, by the usual convention and by that of the tables from which  $\Delta G^{\circ}$  was obtained, and that of  $\text{H}_2\text{S}$  is nearly 1 if the pressure is 1 atm. If the precision of other terms is sufficient to justify it, the activity coefficient of the  $\text{H}_2\text{S}$  may be estimated from the deviation of the gas from ideality. If the aqueous solution is rather dilute, the activity coefficients of the  $\text{H}^+$  and of the  $\text{Co}^{2+}$  may be calculated by use of the Debye-Hückel theory. If preferred, we may write  $\text{HCl}$  and  $\text{CoCl}_2$  in place of  $\text{H}^+$  and  $\text{Co}^{2+}$ , but since the fictitious ac-

tivity coefficient of  $\text{Cl}^-$  enters both numerator and denominator to the same power, the same result is obtained. If the solutions are extremely dilute we may without serious error write  $Q_\gamma \approx 1$ , and  $K \approx Q_\alpha$ .

We have arrived at the chief practical application of thermodynamics to physical chemistry. From the  $Q_\alpha$  for a given reaction we can relate the concentrations or partial pressures of the substances in equilibrium with one another, and hence can calculate, for any given initial conditions, whether the reactions as written will proceed to the right or left, and to what extent, if allowed to proceed to equilibrium.

The quantity which we have defined as  $Q_\alpha$  was called the equilibrium constant before the application of thermodynamics to chemical equilibria; it is better to call it the equilibrium quotient, and to reserve the name equilibrium constant for the activity quotient characteristic of equilibrium which has been designated above by  $K$ . The reasons for the seemingly arbitrary bases for defining the activity will now become apparent.  $Q_\alpha$  has been traditionally expressed by partial pressures of gaseous constituents, by mole fractions for nonaqueous solutions, and, for aqueous solutions, by concentrations in moles per litre. (The latter is preferably replaced by moles per kilogram of solvent, since this expression does not change with mere expansion of the solution with change of temperature.) With these modes of defining the activity we can keep  $K$  in the same form as  $Q_\alpha$  and even have nearly the same numerical values when the solutions are dilute and the gas pressures are low—both of which conditions have frequently prevailed.

**20. Change of Equilibrium Constant with Temperature and Pressure.**—The equilibrium constant can be expressed as a function of temperature or pressure by finding the corresponding expression for  $\Delta G^\circ$ . By equation (46)

$$\Delta G^\circ/T = \Delta G/T - R \ln J = \Delta G/T - R \ln J_\alpha - R \ln J_\gamma \quad (48)$$

where  $J_\alpha$  and  $J_\gamma$  are the quotients of  $x$ 's and of  $\gamma$ 's of the same form as the activity quotient  $J$ . Combining equation (48) with (23), keeping pressure and composition constant, we obtain

$$[d(\Delta G^\circ/T)dT]_{P,\alpha} = -\Delta H/T^2 - R[d \ln J_\gamma/dT]_{P,\alpha} \quad (49)$$

For arbitrarily chosen compositions we would have trouble in evaluating the last term. If, however, we choose such concentrations and partial pressures as to make each  $\gamma$  nearly unity and hence  $\ln J_\gamma$  very nearly zero, we can make  $\ln J_\gamma$  as small as we please, both at  $T$  and at  $T + dT$ , whereupon the last term of (49) becomes vanishingly small. Thus we find

$$[d \ln K/dT]_{P,\alpha} = -[d(\Delta G^\circ/RT)/dT]_{P,\alpha} = \Delta H^\circ/RT^2 \quad (50)$$

where  $\Delta H^\circ$  is the limit of the heat absorbed for the reaction in which each substance approaches the condition in which its activity coefficient is 1. In obtaining (49) and (50) we used partial derivatives with the formal restriction of constant pressure and composition, but since  $K$  and  $\Delta G^\circ$  are both independent of pressure and composition these apparent restrictions can be dispensed with.

It is noteworthy that, while  $\Delta G^\circ$  is  $\Delta G$  for the reaction in which each activity is 1,  $\Delta H^\circ$  is  $\Delta H$  for the reaction in which each activity coefficient is 1. The conditions for the activity coefficients to be equal to 1 can generally be reached or approached, but in many cases those required to make the activities equal to 1 may be unattainable. This is of no real concern, for we define  $\Delta G^\circ$  by equation (46), using a  $\Delta G$  for attainable conditions for which the activities are known. In subsequent use of  $\Delta G^\circ$  we again obtain a  $\Delta G$  for attainable conditions. The  $\Delta G^\circ$  of formation of  $\text{H}_2\text{O}$  (gas) at  $25^\circ \text{C}$  can be found in available tables. Formally, this is the Gibbs function of formation of water vapour at  $25^\circ \text{C}$  and activity of 1 atm. The activity of saturated water vapour at this temperature is 0.03 atm; while water vapour can be supersaturated to a considerable extent, it seems unlikely that it will ever be obtained at an activity of 1 atm at  $25^\circ \text{C}$ . This unattainable standard state could have been dodged by giving the  $\Delta G$  of formation of water vapour at, say,  $a = 0.01$ , rather than for 1 atm, and putting into the activity quotients of expressions

similar to (46) two sets of activities: those of the system of immediate interest and those for the tabulated state. The  $\Delta G^\circ$  values may be interpreted as merely a convenient and legitimate means of avoiding unnecessary additional labour of calculation.

### III. THIRD LAW OF THERMODYNAMICS

**1. Statement.**—The principle known as the third law of thermodynamics has been due primarily to the German chemist W. H. Nernst (q.v.; 1864–1941), but its significance and its limitations have been gradually developed by a number of workers. It is remarkably difficult to make a defensible statement of the third law which is not so full of restrictive qualifications as to make it practically useless. Its statement by G. N. Lewis and M. Randall (see bibliography) is: "If the entropy of each element in some crystalline state be taken as zero at the absolute zero of temperature: every substance has a finite positive entropy, but at the absolute zero of temperature the entropy may become zero, and does so become in the case of perfect crystalline substances."

Criticism of this statement will be deferred until after an examination of the usefulness of the law. Provisionally accepting it as stated, from measurements of  $C_p$  for both elements and the compounds of interest, one can, by integrating equation (9), find the entropies at some chosen temperature  $T$  for all the substances concerned in a reaction, and thus obtain  $\Delta S$  for the reaction. (If phase transitions occur between 0 and  $T$ , the change of entropy of such transitions must be included.) Combining this with the calorimetrically determined heat of the reaction, we obtain  $\Delta G = \Delta H - T\Delta S$ . If the activities of the substances have also been determined we can immediately obtain  $\Delta G^\circ$  and have all quantities of thermodynamic interest. The integration of (9) from  $T = 0$  can be carried out if  $C_p/T^n$  has a limit as  $T \rightarrow 0$  for positive  $n$ , not necessarily an integer; for all substances investigated this requirement is easily met. For most substances  $C_p/T^3$  approaches a limit; for metals having free electrons, calculations indicate that  $C_p/T$  approaches a small non-zero value.

**2. Evaluations.**—Tests of the third law have been made by carrying out measurements of heat capacities of substances involved in reactions for which the entropy change has been independently measured by the change of  $\Delta G$  with temperature. Satisfactory agreement is found in the great majority of cases, but a number of exceptions occur. To say that these are not perfect crystalline substances is not a satisfactory answer unless an independent criterion of perfection is available. The case of hydrogen is interesting. In accordance with certain quantum mechanical rules, normal hydrogen,  $n\text{-H}_2$ , may be considered a mixture of parahydrogen,  $p\text{-H}_2$ , with the nuclear spins aligned in opposite directions, and orthohydrogen,  $o\text{-H}_2$ , with the spins in the same direction. (See HYDROGEN: Orthohydrogen and Parahydrogen.) In the presence of an effective catalyst the  $o\text{-H}_2$  changes to  $p\text{-H}_2$  at low temperatures, and as absolute zero is approached it becomes nearly pure  $p\text{-H}_2$ . If its heat capacity is measured in the presence of a catalyst which maintains the mixture of  $o\text{-H}_2$  and  $p\text{-H}_2$  in their equilibrium amounts, entropies at higher temperatures are obtained which are consistent with measurements by other means. However, during heat capacity measurements in the absence of a catalyst, the  $n\text{-H}_2$  persists as a mixture of  $\frac{1}{2} o\text{-H}_2$  and  $\frac{1}{2} p\text{-H}_2$  to very low temperatures. Heat capacities so measured, combined with the assumption of zero entropy at the absolute zero, lead to an apparent entropy at moderate or high temperatures which is in disagreement with that consistent with the reactions of hydrogen by about 4 cal/mole-deg. If this value is used to calculate chemical equilibria, the pressure or concentration of hydrogen so found can be in error by nearly a tenfold factor. For a few other substances the corresponding error may amount to as much as a threefold factor, but in the great majority of cases there is very good agreement.

### IV. OTHER THERMODYNAMIC RELATIONS

**1. Thermodynamic Quantities from the Structure of Molecules.**—The determination of the structure of molecules, including interatomic distances and angles (see STEREOCHEMISTRY), has made possible the calculation of many important thermo-

dynamic functions of substances, particularly when in the dilute gaseous state. In a dilute gas, where the molecular interactions can be neglected, the energy of the system can be taken as the sum of the energies of the separate molecules, and the internal and translational energies of a molecule are independent. The internal energy may be further subdivided into electronic, vibrational, and rotational. For the monatomic gases, such as sodium and chlorine, the electronic energy is the only internal energy which needs to be considered. Arranging the electronic states in order of ascending energies, we will call that of lowest energy the ground state and those of higher energy the first, second, etc., excited states. If sodium vapour is held at constant temperature, atoms will exchange energy until at equilibrium the average fraction in any state will depend only on the temperature and the relative energy of the states. The exchanges may be represented by the reaction  $\text{Na}(o) = \text{Na}(i)$ , which indicates the change of a mole of Na in the ground state to the  $i$ 'th electronic state. At moderate temperatures practically all the atoms are in the ground state, and the vapour exhibits the heat capacity ( $C_p = \frac{5}{2}R$ ) characteristic of the translational energy of a monatomic gas. If all the atoms in the vapour could be maintained in a single excited state it is plausible to assume that its molal heat capacity would also be  $\frac{5}{2}R$ , and for the change of  $\text{Na}(o)$  to  $\text{Na}(i)$ ,  $\Delta C_p = 0$ ,  $\Delta PV = 0$ , and hence  $\Delta H = \Delta E$ . (The heat capacities discussed above are for sodium vapour with all its atoms in the ground state, or with all in the  $i$ 'th state. The heat capacity of the mixture is greater than that characteristic of any pure state because, on raising the temperature, the proportion of atoms in high energy states is increased. This additional heat capacity is the  $C_p$  discussed below.) Since  $\Delta C_p$  is zero, the change of entropy is independent of temperature; and, assuming from the third law that the entropy change is zero at  $T = 0$ , it is also zero at any other temperature, and  $-RT \ln K = \Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = \Delta E^\circ$ . From this we derive

$$n_i/n_o = e^{-(E_i - E_o)/RT} \quad (51)$$

where  $n_i$  is the number of atoms in the  $i$ 'th electronic state,  $n_o$  is the number in the ground state, and  $E_i - E_o$  is the difference in energy, per mole, between the  $i$ 'th state and the ground state. An equation of this form holds for each excited state, and the composition of the total equilibrium mixture can then be characterized by the sum

$$\frac{n_i/n_o}{Q_e} = \frac{Q_e}{Q_e} = 1 + e^{-(E_1 - E_o)/RT} + e^{-(E_2 - E_o)/RT} + \dots = \sum e^{-(E_i - E_o)/RT} \quad (52)$$

where  $Q_e$ , called the partition function for the electronic states, is defined by the above summation and  $n_i$  is the total number of molecules in the mixture. Taking the derivative of (52) with respect to temperature and multiplying by  $RT^2/Q_e$ , we obtain

$$\frac{RT^2(d \ln Q_e/dT)}{Q_e} = -\frac{(R/Q_e)dQ_e/d(1/T)}{Q_e} = \frac{\sum (E_i - E_o)e^{-(E_i - E_o)/RT}}{\sum e^{-(E_i - E_o)/RT}} = \Delta E_e = \Delta H_e \quad (53)$$

where  $\Delta E_e$  or  $\Delta H_e$  is the energy per mole of the mixture above the ground state due to the occurrence of electronically excited states. Taking the derivative of (53) with respect to temperature gives  $\Delta C_p$ , the contribution to the heat capacity due to the change in the proportions of the electronic states. Dividing this by  $T$  and integrating from  $T = 0$  to  $T = T'$ , we obtain

$$\Delta S_e = R[\ln Q_e + T'd \ln Q_e/dT]_{T'} \quad (54)$$

$$\Delta G_e = \Delta H_e - T'\Delta S_e = -RT' \ln Q_e \quad (55)$$

and for the change in entropy and Gibbs energy respectively, for the change from the ground state to the equilibrium mixture of the various electronic states.

In the case of sodium vapour in a magnetic field of 1,000 gauss, two electronic states have very nearly equal energies; one is higher than the other by only about 0.27 cal/mole. The next higher state is about 48,470 cal/mole above the ground state, and is accompanied by another having only a fraction of a calorie per mole higher energy. At about 48,510 cal/mole above the ground state there are four more states which differ from each other by only a

fraction of a calorie per mole. In weaker magnetic fields the differences within these groups of states are proportionally smaller, and at all except extremely low temperatures we may write the electronic partition function for sodium as  $Q_e = 2 + 2e^{-48,470/RT} + 4e^{-48,510/RT}$  where  $R$  is in calories per mole-degree. This grouping together of states of nearly equal energy leads to negligible error; but to have counted the group of states of nearly equal energy, called degenerate states, as only one state would generally lead to serious error. For atomic chlorine the electronic partition function  $Q_e = 4 + 2e^{-2,517/RT}$ , with  $R$  again expressed in calories per mole-degree. At 1,000° K one can find from the above that about 88% of the atomic chlorine is in one or the other of the four states of low energy, and about 12% is in one of the pair of states with 2,517 cal/mole higher energy. States of still higher energy exist, but the fraction of the mixture in such states is so small at readily attainable temperatures that they can be ignored, and have not been written in the above partition function.

For most stable diatomic and polyatomic molecules, the excited electronic states are of such high energy that they make negligible contributions to the corresponding electronic partition function. However, there are some exceptions; in particular, degenerate states need to be taken into account. For these molecules the vibrational and rotational energies are important. Generally no serious error is made by treating the rotational and vibrational energies as independent of one another. In this case, the successive rotational levels can be calculated from the principal moments of inertia, which can be found from the interatomic distances and angles as determined by X-ray or electron diffraction studies and from the spectra of the molecules. (See ELECTRON DIFFRACTION; MOLECULAR SPECTRA; SPECTROSCOPY, X-RAY.) The vibrational levels can also be found from spectroscopic studies; from these values rotational and vibrational partition functions,  $Q_r$  and  $Q_v$ , analogous to  $Q_e$ , can be constructed. Finally, from the quantum mechanical theory of molecules within an enclosure, the translational energy levels and the corresponding translational partition function can be found. From each of these partition functions a contribution to the entropy or to the Gibbs energy can be calculated, analogous to the electronic contribution given by (54) and (55). Except for the slight error made by treating the electronic, vibrational, and rotational energies as independent, the sum of these contributions to the entropy gives the total entropy for the substance in dilute gaseous state. To obtain equilibrium constants for reactions involving diatomic or polyatomic molecules one also needs the heat of the reaction at some temperature; even this can sometimes be obtained from spectroscopic measurements.

The equilibrium species present in a simple gas at high temperatures may be of some interest. From tables (presumably calculated from partition functions derived from spectroscopic data) one can find that the standard Gibbs energy of formation of H, monatomic hydrogen, is -18,523 calories at 5,000° K. This Gibbs energy is given relative to ordinary (diatomic) hydrogen,  $\text{H}_2$ ; from which we obtain, for  $\text{H}_2 = 2\text{H}$ :  $\Delta G_{5,000}^\circ = -37,046$ ,  $\log K = \Delta G/2.3RT = 1.620$ , and  $K = (a_{\text{H}})^2/a_{\text{H}_2} = 41.7$ . At low pressures the activity is very nearly the same as the pressure, and the standard states have been chosen to be consistent with the atmosphere as the unit of pressure. When the pressure of monatomic hydrogen is 0.1 atm,  $P_{\text{H}_2} = (0.1)^2/41.7 = 0.00024$  atm, from which we note that very little diatomic hydrogen will be present at this temperature.

At 5,000° K the monatomic hydrogen is dissociated to some extent into protons and electrons, and for  $\text{H} = \text{H}^+ + e^-$  we can also find, from tables,  $\Delta H(0^\circ\text{K}) = 313.5$  kcal. The translational energies of gaseous molecules within an enclosure can be calculated by means of quantum mechanics, and a translational partition function can be developed. From this one can derive the formula

$$G(\text{trans}, T) - G(\text{trans}, 0) = RT\left(-\frac{3}{2} \ln M - \frac{5}{2} \ln T + \ln P + 3.657\right) \quad (56)$$

in which the numerical constant 3.657 is a condensation of several constants and is valid only when the molecular weight is expressed in grams per mole, the temperature in degrees Kelvin, and the

pressure in atmospheres. In this case molecular rotation and vibration are absent and the effects of electronic and nuclear spin mutually cancel. Postponing consideration of the electronically excited states of H, we find for  $H_{gr} = H^+ + e^-$ :

$$\ln K = -\Delta G^\circ/RT = \frac{3}{2} \ln M_e + \frac{5}{2} \ln T - 3.657 - 313,500/RT \quad (57)$$

where  $H_{gr}$  means monatomic hydrogen in its electronic ground state or state of lowest energy, and  $M_e$  is the "molecular weight" or "atomic weight" of the electron, or the weight of one faraday equivalent of electrons. From this we obtain

$$K = (a_{H^+})(a_e)/(a_{H_{gr}}) = 1.15 \times 10^{-21}$$

Again assuming that the activities are nearly equal to the partial pressures, although the coulombic interactions will make this approximation relatively poor, we find that, when the pressure of ground state H is 0.1 atm.,  $P_{H^+} = P_e = 1.07 \times 10^{-6}$  atm.

The amount of H in electronically excited states proves to be rather difficult to define. The ground state consists of two states of practically identical energy; the next level, at  $313 \times (1 - \frac{1}{4})$  kcal higher energy, has eight states; and the  $n$ th level, at  $313 \times (1 - 1/n^2)$  kcal, has  $2n^2$  states. For  $n \geq 10$ , the energy is almost 313 kcal above the ground state, and the ratio of the number of atoms in state  $n$  to that in the ground state is about  $2n^2/2e^{-313,000/RT}$ , or about  $2 \times 10^{-14} n^2$ . At first sight there appears to be no limit to how high the quantum number  $n$  may go, and with  $n = 10^7$  there would be more atoms in this level than in the ground state. However, the average distance between the electron and its nucleus varies as  $n^2$ , and with  $n = 15$  this distance is more than 1,000 Å, while in a gas at 0.1 atm and 5,000° K the average distance of nearest neighbour gas molecules is about the same. Obviously, very strong interactions would occur between the excited atom and its neighbours, while our use of partition functions of molecules to calculate amounts of the gaseous species requires the assumption that the interaction of neighbouring molecules is very weak. In the gas described above the distinction between atoms in highly excited states and those which are ionized becomes meaningless.

## 2. Effects of Gravitational, Centrifugal, and Other Fields.

—In most of the applications of thermodynamics it is generally assumed that the quantities of thermodynamic interest are determined by temperature, pressure, and concentration, and that gravitational and other fields and surface tension have no appreciable influence on the processes under consideration. This assumption is usually justified but under some conditions these effects can be important.

The reversible lifting of a body in a uniform gravitational field produces no thermal change and thus no change of entropy. The well-known cooling of air when rising due to thermal convection or to deflection by a mountain slope results from the adiabatic expansion of the gas; the change of height operates only indirectly by furnishing the pressure gradient. If the gas is lifted in a closed container so that no pressure change occurs, the change of height produces no change of temperature.

For a system in equilibrium in a uniform gravitational field the temperature is uniform and the pressure varies according to the relation  $dP/dh = -\rho g$  where  $\rho$  is the density. For an ideal gas this gives, on integration,  $P = P_0 e^{-Mg(h-h_0)/RT}$  where  $M$  is the molecular weight,  $g$  is the acceleration of gravity, and  $P_0$  is the pressure at height  $h_0$ . For a mixture of dilute gases the partial pressure of each obeys the above equation, using its appropriate molecular weight; hence a gaseous mixture is partially separated by a gravitational field, but this is appreciable only if convection is prevented. Sampling of the upper atmosphere indicates that even in the stratosphere too much mixing occurs to permit a significant separation.

The effect of gravity offers the interesting theoretical possibility of obtaining fresh water from seawater. Several places have been discovered at which the ocean depth exceeds 10,000 m (more than 6 mi). At this depth the hydrostatic pressure of the seawater exceeds that of a column of fresh water by about 27 atm because of the difference in density. The osmotic pressure of seawater of

average salt concentration is about 23 atm; hence if a pipe closed at the bottom by a semipermeable membrane and filled with fresh water reached to a depth of 10,000 m, the excess of pressure over the osmotic pressure would cause a flow of fresh water through the membrane and out the top of the pipe. This appears to violate the second law of thermodynamics, but the driving force of the process would be furnished by the mixing of the seawater due to ocean currents. (If the seawater were stagnant and at constant temperature, the equilibrium concentration of salt at 10 km depth would be approximately twice as great as that at the surface, and fresh water in the pipe would flow through the semipermeable membrane into the saltwater.)

Cycles involving the change of magnetic field have been used to attain a very close approach to absolute zero. A large increase of entropy accompanies the change of liquid to vapour at constant temperature; if the change occurs without permitting a flow of heat the temperature is greatly lowered. This process is the one most commonly used in artificial refrigeration. It can produce temperatures down to about 2° K, but at still lower temperatures the vapour pressure of helium (the lowest boiling substance) becomes too small to be utilized for further cooling. In the discussion of partition functions (see preceding section) it was noted that sodium atoms in dilute vapour possess two states of nearly equal energy and that the difference in energy is proportional to the strength of the magnetic field. At 50,000 gauss the difference is about 13 cal/mole, and in the field due to the earth (about 0.5 gauss) the energy difference is 0.00013 cal/mole. At temperatures of 2° K or lower other electronic states are entirely negligible, and the electronic partition function may be written as  $Q_e = 1 + e^{-E_m/RT}$  where  $E_m$  is the energy of one state above the other, due to the magnetic field—13 and 0.00013 for the strong and weak fields respectively. Substituting in (54) we find that the entropy in the weak field is about 1 cal/mole-deg larger than in the strong field. If sodium vapour could be cooled to 2° K in the strong field, and if the field were then allowed to diminish to that of the earth while the temperature remained constant, the entropy of the vapour would increase while heat was absorbed from its surroundings. If, instead, the field were diminished while heat flow was prevented, no total change of entropy would occur, for the increase expected because of lowering the field would be compensated by the decrease due to the lower temperature. This process cannot be carried out with sodium vapour because no detectable sodium vapour persists at low temperatures, and the interactions of sodium atoms in metallic sodium bring about entirely different groups of energy levels. However, there are some salts, among which is ammonium ferric alum, which possess ions having energy levels whose behaviour in a magnetic field is similar to that of sodium vapour. Here the ferric ion has states of almost identical energy in a very weak magnetic field, but in a strong field at low temperatures nearly all the ions accumulate in that of lowest energy. On demagnetization they redistribute among the states of now nearly equal energy, with a lowering of temperature. The details are not as simple as the above description implies: the electric field of the neighbouring ions leads to a separation of some of the states which would otherwise have like energies in the absence of the magnetic field, and further, at very low temperatures the magnetic fields of neighbouring ions interact, so that they can no longer be considered as possessing independent energy levels and the change of entropy can no longer be obtained by relations analogous to (54). These interactions set limits to how near absolute zero a system can be cooled by the use of any given cycle.

**THERMOELECTRICITY** refers to effects that arise from the interaction between currents of heat energy and electrical

energy in any material. This interaction permits direct generation of electric power with a heat unit as small as a kerosene lamp or kitchen stove. The Soviet Army used such devices to power portable radio transmitters during World War II. In the 1960s a 5,000-watt thermoelectric generator was made for the U.S. Navy, and production of small thermoelectric refrigerators was underway in the U.S.S.R. and the U.S.

There are three basic thermoelectric phenomena: the Seebeck, Peltier, and Thomson effects. Related nonthermoelectric manifestations of interest are thermal conduction and Joule heating.

The familiar nonthermoelectric phenomenon in which heat energy flows in proportion to the temperature difference between points in a body is called thermal conduction. Mathematically, the thermally conducted heat energy  $Q_k = \kappa \Delta T$ , where  $\kappa$  is the thermal conductance of the material and  $\Delta T$  is the difference in temperature imposed across the material (see HEAT).

Joule heating is simply the irreversible production of heat energy by the current in an electrical circuit (as in the resistor wires of an electric toaster). The amount of such energy (the so-called Joule heat  $Q_j$ ) is equal to the square of the current  $I$  multiplied by the electrical resistance  $R$  of the circuit; i.e.,  $Q_j = I^2 R$  and is independent of the direction of the current.

**Seebeck Effect.**—Consider dissimilar materials A and B (not necessarily solids) joined to form a complete circuit (fig. 1). If one junction is kept at a high temperature  $T_h$  and the other junction is at a cooler temperature  $T_c$ , current flows in the circuit (Seebeck effect). The so-called Seebeck voltage, the open circuit voltage, that is induced is roughly proportional to the difference in temperatures. An obvious application of the effect would be a generator that produces voltage by applying a temperature difference to the junctions of two dissimilar materials.

The effect was discovered by the German physicist Thomas Johann Seebeck (1821) when he detected a magnetic field around such a differentially heated circuit. The finding led him to the unwarranted conclusion that the earth's magnetic field is produced by the temperature difference between the equator and the poles.

Mathematically the Seebeck voltage  $V$  is given by

$$V = \int_{T_c}^{T_h} \alpha dT$$

where  $T$  is the absolute temperature and  $\alpha$  is the factor of proportionality called the Seebeck coefficient. If  $\alpha$  is independent of temperature,  $V$  is proportional to  $T_h - T_c = \Delta T$ .

The Seebeck coefficient can have either a positive or a negative sign. A material having a negative  $\alpha$  is referred to as an n-type material, while a material having a positive  $\alpha$  is referred to as a p-type material. These sign conventions are consistent with those used in the field of semiconductors.

**Peltier Effect.**—If an electric current from an external source (e.g., a battery) flows in the circuit of fig. 1, the two junctions (initially at the same temperature) will develop a temperature difference. Thus in the Peltier effect electric current acts to cool one junction and to heat the other; reversal of current gives the opposite temperature effect at each junction. After the Joule heat is subtracted, the amount of heat energy absorbed or evolved at each junction will be proportional to the electric current and represents the contribution of the Peltier effect. Since one junction is cooled when current flows, the effect can be applied to the development of refrigeration devices.

The effect was discovered by the French physicist J. C. A. Peltier (1834) when he found that Joule heating failed to account for all of the heat energy evolved at a junction. The physical origin

of the Peltier effect may be understood by thinking of electrons as being evaporated from material A at the junction and being condensed on material B. Unless the energy required for evaporation is exactly equal to that required for condensation, a net amount of heat energy must be absorbed from or lost to the surroundings of the junction. This is the Peltier heat  $Q_p = \pi I$ , where  $I$  is the current and  $\pi$  is the proportionality factor called the Peltier coefficient. Lord Kelvin (William Thomson) showed through thermodynamic analysis that the Peltier and Seebeck coefficients are connected by the relation  $\alpha = \pi/T$ .

**Thomson Effect.**—When electric current passes through a circuit composed of a single material that has a temperature difference between any two of its points, the Thomson effect is manifested as the evolution or absorption of heat. After correction for Joule heating, the amount of this heat energy is found to be proportional to the current and to the temperature difference. Whether heat energy is absorbed or evolved depends on the direction of the current relative to the temperature gradient in the circuit. Lord Kelvin (1854) predicted this effect on theoretical grounds from thermodynamic considerations.

To examine the physical origin of the Thomson effect, consider a group of electrons crossing an imaginary interface at temperature  $T_1$  (fig. 1). The electrons theoretically must be in equilibrium at this temperature and thus must have a specific amount of energy. As they cross the interface at  $T_2$ , they must have the energy associated with the second temperature. If these two energies are unequal, the net difference must be absorbed from or supplied to the surroundings. The amount of heat energy exchanged with a given element of material should thus be proportional to the current and the temperature difference.

The proportionality constant is called the Thomson coefficient  $\tau$ ; and the Thomson heat  $Q_\tau = \tau I \Delta T$ , the  $\tau$  representing a sort of specific heat for the electrons, except that it can be either positive or negative. Lord Kelvin thermodynamically derived the relation  $\tau = T(d\alpha/dT)$ .

**Applications.**—Thermoelectricity may be used in power generation and refrigeration. Consider a power generator shown by fig. 2.  $R_L$  is the load resistance ( $T_h$ ,  $T_c$ , A, and B have the same meaning as in fig. 1). The efficiency  $\epsilon$  of such a device may be written  $\epsilon = I^2 R_L / Q$ , where the numerator is the power delivered to the load and  $Q$  represents the rate at which energy is removed from the hot junction. To maximize power output it is necessary to produce the largest possible voltage; thus the Seebeck coefficient  $\alpha$  should be large. In practice it can usually be made as large as desired by proper selection of materials in arms A and B. These should also have low electrical resistivity  $\rho$  to minimize Joule heat and internal resistance in the generator. Since heat energy is carried away by thermal conduction through A and B, the arms also should have low thermal conductivity  $\kappa$ . Hence the requirements for materials used in thermoelectric power generators are high  $\alpha$ , low  $\rho$ , low  $\kappa$ . If the efficiency is maximized by varying the load  $R_L$ , it is found that the efficiency depends on these material parameters through what is called the figure of merit  $Z = Tz = T\alpha^2/\rho\kappa$ . The higher the figure of merit the greater the efficiency for power generation. (For efficient thermoelectric refrigeration, materials should also have a high figure of merit.)

The efficiency of a thermoelectric generator may be written

$$\epsilon = \frac{\Delta T \sqrt{1 + Z} - 1}{T_h \sqrt{1 + Z} + T_c/T_h}$$

where  $T_h$  is the temperature of the hot junction,  $T_c$  is the temperature of the cold junction,  $T = (T_h + T_c)/2$  and  $\bar{z}$  is the average value of  $z$  (i.e.,  $\alpha^2/\rho\kappa$ ) over the temperature range. Although this expression is only exact if  $z$  is temperature independent, it is sufficiently accurate for almost all applications. The first term ( $\Delta T/T_h$ ) is the Carnot efficiency; i.e., the maximum theo-

FIG. 2.—BASIC THERMOELECTRIC POWER GENERATOR

retical efficiency obtainable between  $T_h$  and  $T_c$  (see THERMODYNAMICS). The remainder of the expression represents the efficiency of the thermoelectric device itself. With materials available in the 1960s with a figure of merit of about 1 from 300° to 1,500° K, a theoretical efficiency of about 20% was calculated; because of engineering problems the empirical efficiency was about half that (see ENERGY CONVERSION, DIRECT).

The important parameter for refrigeration is the coefficient of performance  $\phi_c$ . This quantity is defined as the ratio of energy removed (from the cold junction) to the device's power input, calculated as

$$\phi_c = \frac{T_c}{\Delta T} \frac{\sqrt{1 + \bar{T}_z} - T_h/T_c}{\sqrt{1 + \bar{T}_z} + 1}$$

The first term ( $T_c/\Delta T$ ) is the  $\phi_c$  for a Carnot refrigerator and the second term represents the efficiency of the thermoelectric circuit (see REFRIGERATION: *Thermoelectric Refrigeration*).

**THERMOMETRY** means the measurement of temperature. Temperature may be defined as the thermal state of a body as observed in its tendency to lose or gain heat energy from other bodies. Instruments used in such measurement are known as thermometers, or sometimes, when temperature exceeds red heat, as pyrometers.

This article, treating the subject in a generally historical order, is divided into the following sections:

- I. Early Development
  1. Thermometry
  2. Pyrometry
- II. Further Developments and Various Inventions
- III. Development of Precise Thermometry
  1. Expansion Thermometry
  2. Optical and Radiation Thermometry
  3. Electrical Thermometry

## I. EARLY DEVELOPMENT

**1. Thermometry.**—Of the two commonly practised basic methods of measurement, namely, by contact and by radiation, only the first was known for more than two centuries following the inventions of the faulty air thermometer of Galileo Galilei and the hermetically sealed Florentine thermometers first developed in the middle of the 17th century (see HEAT: *Temperature*).

Gabriel Daniel Fahrenheit (1686–1736), a modest German instrument maker, native of Danzig and long a resident of Holland, is said to have invented in 1714 the mercury-in-glass thermometer and the scale of temperature by which his name is daily remembered in some English-speaking countries. In devising a scale for his thermometer, Fahrenheit chose as the zero the lowest temperature obtainable with a mixture of ice and common salt, and first proposed to divide the interval between this temperature and that which is normally found to characterize the blood of a healthy man into 12 divisions, subsequently increasing the number to 96, purely as an arbitrary measure of convenience. Fahrenheit had previously shown that pure water while freezing in the presence of pure ice always gave the same reading on his thermometer, and he invented the mercury thermometer so that he could observe the constancy of the boiling point of water, a report of which he had

read in the *History of the Sciences* issued by the Royal Academy of Paris. These two points on his thermometer (later fully recognized as fixed points) were observed at the 32nd and 212th divisions, respectively. His thermometer must have had a rather uniform bore for him to have observed 212° F as the boiling point of water, but not precisely so, because the blood temperature of a healthy man was observed as 96°, and is now known to be 2° to 3° higher. The so-called Fahrenheit scale, having an interval of 180° between the freezing and boiling points of water, went rapidly into general use, and was still retained in the U.S. and Canada during the 1960s, particularly for meteorological work, because of its small degrees. R. A. F. de Réaumur (1683–1757), French naturalist, proposed in 1730 to divide the interval into 80°, and his scale is used in many countries. Anders Celsius (1701–1744), Swedish astronomer at Uppsala, whose name was to be used eventually to express temperatures as degrees Celsius (°C) on the International Practical Temperature Scale, is credited with first proposing to make the interval 100°, as it is on the centigrade scale.

During the century after Fahrenheit, the mercury-in-glass thermometer (fig. 1) became an instrument of useful precision and the basis of all temperature measurements, the thermal expansion of liquids being the only recognized means for measuring temperatures. The principles of thermodynamics were not well established, nor did the knowledge of the behaviour of gases extend much beyond the information afforded by the laws of Robert Boyle (discovered independently by E. Mariotte) and J. Charles (anticipating J. L. Gay-Lussac, 1802). No material success was attained in the experimental use of a gas thermometer, and measurements were limited to the range of the mercury thermometer graduated from –40° to 300° centigrade. The lower limit was determined by the freezing of mercury at –39.87° C (modern value), and the upper range was roughly limited by its high vapour pressure, which reaches atmospheric pressure at approximately 357° C (675° F). The thermometers of that period had to be kept well below this temperature because within the thermometer in the

Degrees Celsius or Centigrade (°C) Versus Degrees Fahrenheit (°F)

°C	°F	°C	°F
5,000	9,032	100	212
2,000	3,632	0	32
1,500	2,732	–40	–40
1,000	1,832	–100	–148
500	932	–273.15	–459.67

To convert °F into °C, first subtract 32, then take 1/5 of the remainder. To convert °C into °F, first multiply by 1/5, then add 32.

capillary space above the mercury there was no gas under pressure, as usually found in thermometers many years later, to prevent the mercury from boiling and from distilling into the capillary. The upper limit was not affected by the softening of the glass which would probably have withstood a temperature above 400° C.

**2. Pyrometry.**—In order to measure higher temperatures than these early thermometers could withstand, James Prinsep (1828), interested in alloys of gold, silver, and platinum, and wanting to measure their melting points, made a large bulb of gold connected with a sensitive manometer with which to maintain the gas (air) at constant pressure within, and connected also with a reservoir of olive oil. Temperatures were measured by weighing the oil that had to be removed from the manometer, as the air expanded, in order to maintain the level constant. This could be considered the beginning of gas thermometry. Prinsep's measurements were limited in the upper range by the melting point of gold, found to be 1,063° C near the close of the century. Others, including Sir Humphry Davy, used the Prinsep method without much improvement, until Claude Servais Mathias Pouillet (1836) made a bulb of platinum and improved the experimental procedure, which was further improved in 1847 by Henri Victor Regnault, and in the 1880s by H. L. Callendar and his associates. The high melting point (1,769° C) of platinum extended the upper limit of measurement many hundreds of degrees. Pouillet also studied the relation between temperature and radiation from glowing solids. Thomas Johann Seebeck had discovered in 1821 that electromagnetic changes occur in a closed circuit of two dissimilar metals when the junctions of the metals are maintained at dif-

ferent temperatures, and Antoine Becquerel had tried a platinum-palladium junction in 1830.

The methods of gas thermometry continued to be improved throughout the 19th century. Regnault had shown in 1847 that the gas thermometer could afford precision in the range  $0^{\circ}$  to  $100^{\circ}$  C. He attained a precision sufficient to detect differences in the expansion coefficients of some of the more readily condensable gases, but not of hydrogen and nitrogen, which were found to expand one part in about 273 per degree C at  $0^{\circ}$  C. During this period, the mercury thermometer remained the primary and most reliable means for measuring temperatures in practical applications.

Sadi Carnot had described in 1824 his ideal reversible heat engine, and had endeavoured to prove on theoretical grounds that the efficiency of his ideal engine was the maximum possible and dependent only on the limits of temperature between which it works. Neither Carnot's proof nor that of many others appeared to be fully satisfactory for many years. The mechanical theory of heat, i.e., the interpretation that heat is energy subject to the law of conservation, was slowly displacing the older theory that heat is an imponderable fluid with the power of penetrating all substances. Quoting Callendar, "The honour of placing the mechanical theory of heat on a sound experimental basis belongs almost exclusively to [J. P.]

Joule, who showed by direct experiment that in all the most important cases in which heat was generated by the expenditure of mechanical work, or mechanical work was produced at the expense of heat, there was a constant ratio of equivalence between the heat generated and the work expended and vice versa." Joule reported his long series of brilliant experiments in a series of papers from 1840-43, and in 1848 he wrote to William Thomson (Lord Kelvin) to point out that according to his experiments, the efficiency of Carnot's engine must be proportional to  $1/T$ , the absolute temperature appearing in the equation  $pV = RT$ , representing the combined laws of Charles and Boyle for the expansion of gases. This equation was known to be a good approximation for the air thermometer between  $0^{\circ}$  and  $100^{\circ}$  C if  $T$  be put equal to  $t(^{\circ}\text{C})$  plus 273. At this time, thermodynamics was making rapid strides and the experimental work was all based on the centigrade scale as defined by the mercury thermometer and the value 273 for  $T - t$ . In 1852 Thomson gave as the expression for the efficiency of the Carnot cycle on the evidence of Joule's experiment:

$$W/Q = (t_1 - t_2)/(t_1 + 273) = (T_1 - T_2)/T_1$$

where  $Q$  is the heat energy an engine receives and  $W$  is the work it performs. Thomson had realized that in the ideal heat engine lay a means for measuring temperature independently of the property of any substance. Four years earlier he had proposed for this purpose to write  $W/Q$  equal to a constant, but as the experimental evidence accumulated he proposed in 1854 to define the thermodynamic scale according to the above equation, thus making this

equation exact, and to determine by experiment how far the scale of the gas thermometer departed from the ideal scale. With this object in mind he devised a very delicate method, known as the porous plug experiment, to measure the temperature change accompanying the expansion of a gas in the absence of any conversion of heat to kinetic energy. Joule and Thomson carried out a long and famous series of experiments, and finally reported in the *Philosophical Transactions* (1862) that the deviations of the air thermometer from the absolute scale as above defined are almost negligible, and that in the case of the gas hydrogen, the deviations are so small that a thermometer containing this gas may be taken for all practical purposes as agreeing exactly with the absolute scale at all ordinary temperatures.

It should be carefully noted that the above equation, defining the thermodynamic temperature scale, does not determine any numbers for temperatures, but only defines the ratio of  $T_0$  to  $T_1$  as equal to  $1 - W/Q$ . Thus any number may be selected for one fixed point, for example, the ice point, leaving the intervals between this point and all others such as the steam point subject to experimental determination; or we can select any convenient interval such as that between the ice and steam points, leaving both their values above absolute zero subject to experiment. At the time Lord Kelvin was faced with making one of the selections, Regnault had been using air thermometers in his laboratory in preference to mercury thermometers because of the capricious performance of the latter, and had been accustomed to basing his calculations on the difference between the ice and steam points. Had Kelvin suggested, and the suggestion prevailed, that a number be permanently assigned to the ice point on the thermodynamic scale, the differences of the two scales at all other points would have had to be tabulated, and the lengthy tables revised from time to time in order to fit the results of future experiments. Kelvin chose to suggest that the ice-steam interval be fixed at  $100^{\circ}$  and this suggestion prevailed until 1954. (See below *The International Practical Temperature Scale*.) The thermodynamic scale is known simply as the Kelvin scale, temperatures on it being designated  $^{\circ}\text{K}$ . The symbol in equations is usually  $T$ . A thermodynamic scale with the ice-steam interval fixed at  $180^{\circ}$  as in the Fahrenheit scale may be defined as  $9/5 T$ . Called the Rankine scale, it came to be used in some engineering work; to convert to degrees Rankine ( $^{\circ}\text{R}$ )  $459.67$  is added to  $^{\circ}\text{F}$ .

**3. Further Developments and Various Inventions.**—Although the measurements of Regnault in the 1840s and '50s with his gas thermometers in the range  $0^{\circ}$  to  $100^{\circ}$  C were in error by a few tenths of a degree according to modern data, he was probably attaining a precision of about  $0.1^{\circ}$ , and his mercury thermometers did not compare favourably with this precision, varying erratically by tenths of a degree within that range and much more at higher temperatures. Very little was known at the time about annealing glass, so it was customary to age the green or new thermometers for many weeks, during which the ice point would slowly rise by a degree or more as the strains in the glass slowly decreased. These strains would never disappear and the thermometers would give readings at the fixed points (such as ice and steam) differing by tenths of a degree, sometimes changing for months. On the other hand, it was thought that the gas thermometer was providing measurements agreeing with the Kelvin scale to better than  $0.1^{\circ}$ . For these reasons the gas thermometers, especially the constant-volume hydrogen thermometer, came to be regarded as the ultimate standard for laboratory work at ordinary temperatures.

The mercury thermometer was also improved during this period by the introduction of nitrogen into the capillary bore above the mercury. Before this time the thermometers had been sealed after filling, while the bulb was kept hot enough to run the thread of mercury to the upper end of the stem. Thus when the bulb cooled, the space above the mercury contained only its vapour at a pressure corresponding to the temperature of the space. By introducing nitrogen into the bulb at some lower temperature, the pressure of the gas will increase as the mercury rises, and counteract the vapour pressure rising with increasing temperature. The use of nitrogen not only prevents the mercury in the bulb from vaporizing but also retards the vaporization into the space occupied by

FIG. 1.—MERCURY-IN-GLASS THERMOMETERS

(A) Extra hard glass for  $1,200^{\circ}$  F ( $649^{\circ}$  C) in  $2^{\circ}$  divisions; (B) precision type for  $200^{\circ}$  C in  $0.2^{\circ}$  divisions; (C) Beckmann differential,  $6^{\circ}$  range in  $0.01^{\circ}$  divisions; (D) common type for indoor or outdoor use

the nitrogen. In order to best match the varying pressure of the mercury, the proper size of the expansion chamber at the upper end is calculated according to the size of the bore. This calculation is necessary because pressures of a few hundred pounds per square inch are required at the highest temperatures at which the thermometer can be used. These gas-filled thermometers extended the useful range toward the softening temperature of the glass and in order to take full advantage of the new method of filling, harder glasses were developed; *i.e.*, glasses with higher softening temperatures. The first of these were the so-called *verre dur* of France and the type Jena 16, III of Germany. Filling the thermometers with nitrogen spoiled them for the most precise laboratory measurements, because the varying pressures made the scale nonuniform and prevented the application of corrections, but it made them better for general and industrial applications. The useful range was raised to nearly 500° C (932° F), although the accuracy above 400° C was low.

Another invention of the period was the clinical thermometer in a form much as it is currently known. This is essentially a maximum-reading thermometer; that is, designed to indicate the highest temperature to which it has been subjected after the mercury has been shaken down. It is made while the glass is soft by collapsing a bubble blown in the stem between the bulb and the part of the stem to be calibrated. Expert workmanship closes the bore or passage almost completely so that as the temperature falls the mercury thread breaks at the constriction, leaving all that has remained above to be observed at leisure. The bulbs of these thermometers are made small, cylindrical, and thin-walled, so that they will come up to the maximum temperature as rapidly as possible. Most clinical (also called medical or fever) thermometers require three minutes or more for all the mercury to reach the body temperature. The small bulbs require that the bore also be exceptionally small, and this requirement in turn has led to the so-called lens-front stems designed to magnify the thread of mercury for easier reading (fig. 2). The scales of these thermometers range from about 33° to 42° C or 92° to 108° F.

Other developments of the period were the resistance thermometer of fine platinum wire first tried by W. Siemens in 1871 with-

but its use in pyrometric measurements has been limited mainly to industrial applications.

## II. DEVELOPMENT OF PRECISE THERMOMETRY

**1. Expansion Thermometry.**—The researches of Callendar and his associates at the Imperial College of Science, London, and the work of P. Chappuis at the Bureau Internationale des Poids et Mesures, Paris, from the late 1880s to the early 1900s were the beginnings of modern precise thermometry. Chappuis undertook the task of comparing the temperature scales of carefully made hard-glass mercury thermometers (not nitrogen-filled) and a constant-volume hydrogen thermometer having a platinum-iridium bulb. This work covered the range from 0° to 100° C and was designed to establish standardized measurements in many countries by supplying mercury thermometers thus calibrated. The probable accuracy per degree was stated by Chappuis to be 0.002°. Callendar developed a compensated constant-pressure gas thermometer with a glass or porcelain bulb and a delicate, sensitive manometer for the close maintenance of a constant pressure, and carried his measurements beyond the boiling point of sulfur (reported with Ezer Griffiths to be 444.53° C). His interests led him to develop also the platinum resistance thermometer as an instrument of great precision, and to compare it with the gas thermometer up to about 550° C, and to devise the so-called Callendar formulas for expressing the relation between resistance and temperature. Applying these equations for extrapolating, he determined melting points for silver and gold that deviated by only 0.8° and 2°, respectively, from the values accepted in the 1960s.

During this time a platinum-rhodium thermocouple was made by Henry le Châtelier to combine with a high resistance galvanometer in portable form for industrial pyrometry. At the same time C. Barus used a platinum-iridium alloy to combine with platinum as a thermocouple. He used a constant-pressure gas thermometer with a porcelain bulb at temperatures up to 1,200° C to calibrate his thermocouples. In 1892 L. Holborn and Wilhelm Wien reported comparing an air thermometer with the platinum-rhodium thermocouple up to about 1,300° C.

An international committee on weights and measures passed a resolution adopted in 1887, that: "The international committee on weights and measures adopts as the standard thermometric scale for the international service of weights and measures the centigrade scale of the hydrogen thermometer, having as fixed points the temperature of melting ice (0°) and the vapour of distilled water boiling (100°) at standard atmospheric pressure, the hydrogen being taken at an initial manometric pressure of one meter of mercury—that is to say,  $1,000/760 = 1.3158$  times the standard atmospheric pressure."

The effect of this action and the work of Chappuis was felt mainly in the limited range between the ice and steam points, and here the matter stood officially for more than a quarter of a century. Chappuis had transferred the hydrogen scale to four primary standard mercurial thermometers of French hard glass; these were used to standardize many other mercury thermometers.

Precise thermometry at high temperatures (*e.g.*, a precision of 0.1° at the melting point of gold [1,063° C] as compared with 0.001° at 50° C) was not attained with gas thermometers until the 1950s. By 1911, however, high-temperature gas thermometry had reached the point where A. L. Day and R. B. Sosman (using bulbs of 10% iridium or 20% rhodium with nitrogen at constant volume) found the melting point of palladium within 2° C. They determined the melting points of eight metals from zinc to palladium, and transferred their measurements to thermocouples, for which they set up interpolation formulas. Duplication of the work probably will not be attempted because other methods are available; however, for the next generation, radiation (optical) methods depended on extrapolation from the melting points of gold and palladium as determined by Day and Sosman.

**2. Optical and Radiation Thermometry.**—As early as 1860 G. R. Kirchhoff had conceived of the complete radiator that has the maximum radiation possible for a given temperature, and that absorbs completely any incident radiation (*see* BLACK BODY). He concluded that the emittance of any opaque substance is equal to

FIG. 2.—CROSS SECTIONS (DOUBLE SIZE) OF THE STEMS OF PRINCIPAL TYPES OF MERCURY-IN-GLASS THERMOMETERS CONTRASTING VARIOUS SCHEMES FOR PROMOTING EASE IN OBSERVING THE POSITION OF THE MERCURY

out success; the pyrometric cones made of clays and other minerals for the ceramic industries, said to be used first by C. Lauth and J. H. L. Vogt in 1882 but highly developed by H. Seger and fully described by him in 1886; the thermopile consisting of a large number of closely grouped thermojunctions, devised by Francesco Rossetti in 1879, for measuring heat radiation; and many improvements in electrical measuring instruments including the moving-coil reflecting galvanometer by J. Arsène d'Arsonval in 1882 (*see* INSTRUMENTS, ELECTRICAL MEASURING). Attempts to estimate very high temperatures by radiation methods met slight success. Josef Stefan had suggested in 1879 from the earlier measurements by John Tyndall that the radiation from incandescent platinum was proportional to the fourth power of the absolute temperature. This was established as the law for total radiation (radiation of all wavelengths) by Ludwig Boltzmann in 1884, who in theory substituted radiation as the working substance in a Carnot cycle. This law has since been known as the Stefan-Boltzmann law, and has had considerable influence on theories of physics,

its absorptance, and that the sum of the two is equal to unity. In the 1890s W. Wien, in studying the spectral distribution of the radiation from a black body, found that the product of the wavelength of maximum intensity of radiation and the absolute temperature is a constant. Later he concluded that the radiation corresponding to any wavelength  $\lambda$  is  $J = c_1 / [\lambda^5 \exp(c_2/\lambda T)]$ , where  $c_1$  and  $c_2$  are constants.

In 1900 H. Rubens and F. Kurlbaum tested this equation at long wavelengths and found their results in serious disagreement. Max Planck suggested that they add  $-1$  to the denominator, and this was found to fit the data; when Planck tried to derive the modified equation, he had to assume that radiation is emitted in multiples of indivisible quanta of energy. Planck's theoretical formula bore directly on thermometric measurements, but in the final analysis the constant  $c_2$  is best evaluated empirically.

E. Becquerel suggested as early as 1864 that high temperatures could be measured by the intensity of red radiation from incandescent bodies, but it was not until 1892 that the first pyrometer using the idea was invented. Le Châtelier designed a photometric instrument for comparing the brightness of a standard oil lamp with that of the source to be measured, and set up empirical formulas by measuring temperatures with other means to calibrate his instrument.

Pyrometers of this type were gradually displaced by disappearing filament optical pyrometers based on an invention by E. F. Morse. If the current through the filament of an electric lamp is slowly increased, the filament glows red at first, then orange, yellow, and white. If this filament is placed in the plane of the image of an incandescent object, in a telescope or microscope, the current through the lamp can be adjusted until the filament or a part of it matches the brightness of the image. When this condition obtains, part of the filament becomes invisible against the background of the bright image, and the current required becomes a measure of the temperature of the object. Red glasses are used in the eyepiece to provide the higher accuracy of monochromatic photometry, and absorbing screens are used between the object and the filament to reduce the brightness of the image to the calibrated range of the filament.

While the instrument itself was being perfected, much work was done to convert experimental data into temperature and to realize more nearly the thermodynamic scale. C. E. Mendenhall (1911) pointed out that the temperature scale based on the Wien-Planck law is in fact based on a single temperature and the selected value of  $c_2$  in the equation, and that a calibration of the instrument is preferably carried out on this basis. By 1926 the value of  $c_2$  was commonly given as 1.432 cm. degrees, but later determinations altered this by a significant amount.

**3. Electrical Thermometry.**—Precise resistance thermometry began with the work of Callendar cited above. He found that previous efforts had evidently been careless of the contamination of the fine platinum wire by the reduction of silica in the porcelain spool on which the platinum was wound. Callendar supported the wire on the edges of clean sheet mica to minimize contamination and strain; he was able to achieve striking precision with such methods. It was fortunate that platinum was available in relatively high purity. Owing to the tremendous difficulties of using gas thermometers in experimental work, use of the Callendar thermometer grew rapidly in the principal laboratories of the world. Various forms of instruments for measuring resistance with sufficient accuracy were developed as their need appeared. Callendar first used an ordinary Wheatstone bridge with a two-lead thermometer. Later improvements included a pair of dummy leads in the parallel arm of the bridge; two leads on each end of the resistor, switched to eliminate the inequality of the two current leads; special forms of the Kelvin double bridge having six decades, with which measurements could be made by a single reading after three of the leads were adjusted to equality; a six-decade Wheatstone bridge arranged to avoid the errors of contact resistances and with means for determining the bridge zero and for commutation of the leads. To attain a precision of 1 part in 10,000,000 or better, the resistor coils of manganin were immersed in a thermostated oil bath. Others chose to use potentiometric

measurements which require four attached leads plus a standard resistor with four leads.

Precise thermometry by thermocouples received a very favorable start when L. Holborn and Day compared a platinum, platinum-10% rhodium thermocouple with the gas thermometer between 300° and 1,000° C and found that a simple parabolic expression  $E = a + bt + ct^2$  would represent the relation between electromotive force and temperature within experimental error (a few tenths of a degree). However, the interpolation formulas of Day and Sosman mentioned earlier were standards of reference for some years. These were not only based on gas thermometer measurements, but represented concurrent researches of the highest order of thoroughness. The precision of electrical measurements attained by their associates was excellent. Improved tables were published including tables for copper-constantan up to 385° C calculated from  $E = a - b(1 - e^{-ct})$ , where  $e$  is the Napierian base. The precision implied in these tables is not attainable without the precise and accurate measurement of small voltages. This was done with a potentiometer of Wolff standard construction by direct comparison with a saturated cadmium cell that was accurate to one or two parts in 100,000. It was a five-dial instrument designed to measure 0.1 microvolt with exactness, and contained no slide-wire usually found in potentiometers designed for less accurate work.

### III. DEVELOPMENT OF INDUSTRIAL THERMOMETRY

**1. Introduction in Industry.**—There are poor records of the slow growth of mercurial thermometry from the time of its invention by Fahrenheit to the end of the 19th century. Use of these devices apparently grew with such developments as steam power and progress in the chemical industry. Mercury thermometers in metal sheaths for ruggedness became articles of commerce known as industrial thermometers. Thus protected they lose some accuracy, but continue to have widespread use. Another instrument of industrial importance was the dial (or pressure-spring) thermometer in which a liquid or gas is enclosed in a metal bulb connected by a capillary metal tube to the pressure spring, a modification of the Bourdon tube in pressure gauges. This may take the form of a spiral or helix of a flattened metal tube that reacts to internal pressure by a slight unwinding. One end of the tube is fixed and the other turns a pointer around the dial scale. The early (before 1911) forms were crude and not compensated for simple errors such as expansion of the fluid in the connecting capillary and spring.

Thermocouples made of base metals had begun to compete with the Le Châtelier couple because of their lower cost and higher thermoelectric power. Iron was still considered unsuitable for a thermocouple element and many combinations of metals and alloys were tried. The most successful of these was invented by M. A. L. Marsh, who combined an alloy of nickel-2% aluminum with nickel-10% chromium. These alloys became known through their trade names Alumel and Chromel, respectively. Chromel-Alumel thermocouples were found to be serviceable as high as 1,100° C and generated an electromotive force (emf) four to five times as large as did the platinum alloy couple of Le Châtelier. Optical pyrometers of the Holborn-Kurlbaum and the Wanner types were in extensive use; likewise radiation pyrometers of C. Féry, C. E. Foster, and C. B. Thwing. A commercial form of Callendar's resistance thermometer was having considerable success. Rugged low-resistance millivoltmeters were available for use with thermocouples and radiation receivers, and the earliest forms of recording instruments were manufactured in considerable quantities. Of these the recorder developed by Callendar with its Wheatstone bridge circuit for his resistance thermometers, various recording millivoltmeters, and the Leeds and Northrup recording potentiometers were outstanding examples.

**2. Industrial Thermometry up to 1920.**—The Faraday Society held a symposium on pyrometry in London in 1917. The consensus of this symposium was that pyrometers needed to be improved in ruggedness and accuracy, and that persons using them needed to learn much more about them. In thermoelectric pyrometry, it was reported that base-metal thermocouples are in-

homogeneous and so cannot provide the accuracy of rare-metal couples. The limitations of radiation pyrometers were discussed, but their unsuitability for portable use was not yet clear. Optical pyrometry had not reached many hands and there was a prevalent idea that too much knowledge was necessary to make good use of it. The disappearing-filament type was competing on even terms with the Wanner (spectrophotometric) instrument.

In Chicago, Ill. (1919), a symposium on pyrometry revealed that the application of pyrometry had been largely made in the high-temperature industries: metals and to some extent glass, ceramics, and portland cement. There was slight scientific interest in industrial thermometry—that is, thermometry below a red heat. A great many engineering colleges were teaching pyrometry and probably a little thermometry. Electrical thermometry had not yet seriously invaded the field of expansion thermometry at lower temperatures. Automatic control (regulation) by means of electrical instruments was barely started, as on-and-off control only.

The symposium showed that base-metal thermocouples had finally found established acceptance for industrial use, the combinations—copper-constantan, iron-constantan, and chromel-alumel—being well known. There was evidence of growing use of industrial forms of potentiometers, particularly the recording potentiometer invented by Morris Leeds, and a number of good recording millivoltmeters. A new form of resistance thermometer appeared in which a fine platinum ribbon was wound on a small tube made of fused quartz, and over this is melted down an outer jacket of the same material, completely sealing in the platinum resistor and protecting it from contamination by industrial gases. This device was to meet much success even for temperatures as high as 900° C. Resistance thermometers made of nickel wire protected for use up to 500° C were also described, but there seems to have been no attention to the molecular change in nickel at about 325° C, which makes this metal unsuitable in this range and beyond.

#### IV. MODERN THERMOMETRY FROM 1920

Other U.S. symposia on temperature were held in 1939, 1954, and 1961. They revealed remarkable growth in temperature scales, precision thermometry, automatic temperature regulation and recording, standards, and extremely low and high temperatures.

**1. The International Practical Temperature Scale.**—The thermodynamic temperature scale has long been recognized as the fundamental reference. However, experimental difficulties inherent in measuring temperature on the thermodynamic scale led the seventh General Conference on Weights and Measures (a diplomatic body representing 33 nations and having the power to set standards for international use) to adopt a scale in 1927 that was more conveniently realized and reproducible. National laboratories used this scale and urged scientists and industrial workers to do the same. The revision in use in the 1960s is known as the International Practical Temperature Scale of 1948. The official text of this scale is contained in the *Comptes Rendus de l'Onzième Conférence Générale des Poids et Mesures* (1960). The following is a translation of the official text for the defining part of the scale by H. F. Stimson in the *Journal of Research of the National Bureau of Standards*, vol. 65A (1961).

Temperatures on the International Practical Temperature Scale of 1948 are expressed in degrees Celsius, designated by °C or °C (Int. 1948), and are denoted here by the symbol  $t$  or  $t_{\text{int}}$ .

The International Practical Temperature Scale is based on six reproducible temperatures (defining fixed points), to which numerical values are assigned, and on formulas establishing the relation between temperature and the indications of instruments calibrated by means of values assigned to the six defining fixed points. These fixed points are defined by specified equilibrium states, each of which, except for the triple point of water, is under a pressure of 101 325 newtons/meter<sup>2</sup> (1 standard atmosphere).

The fixed points of the scale and the exact numerical values assigned to them are given in table 1.

The procedures for interpolation lead to a division of the scale into four parts.

*a.* From 0 °C to 630.5 °C (antimony point) the temperature  $t$  is defined by the formula

$$R_t = R_0(1 + At + Bt^2),$$

TABLE 1. Defining Fixed Points

Exact values assigned. The pressure is 1 standard atmosphere, except for the triple point of water.

	Temperature °C (Int. 1948)
Temperature of equilibrium between liquid oxygen and its vapor (oxygen point).....	−182.97
Temperature of equilibrium between ice, liquid water, and water vapor (triple point of water).....	+0.01
Temperature of equilibrium between liquid water and its vapor (steam point).....	100
Temperature of equilibrium between liquid sulfur and its vapor (sulfur point).....	444.6*
Temperature of equilibrium between solid silver and liquid silver (silver point).....	960.8
Temperature of equilibrium between solid gold and liquid gold (gold point).....	1063

\*In place of the sulfur point, it is recommended to use the temperature of equilibrium between solid zinc and liquid zinc (zinc point) with the value 419.505° C (Int. 1948). The zinc point is more reproducible than the sulfur point and the value which is assigned to it has been so chosen that its use leads to the same values of temperature on the International Practical Temperature Scale as does the use of the sulfur point.

where  $R_t$  is the resistance at temperature  $t$  of the platinum wire resistor of a standard resistance thermometer, and  $R_0$  is the resistance at 0 °C. The constants  $R_0$ ,  $A$ , and  $B$  are to be determined from the values of  $R_t$  at the triple point of water, at the steam point, and at the sulfur point (or the zinc point). The platinum wire of a standard resistance thermometer shall be annealed and its purity shall be such that  $R_{100}/R_0$  is not less than 1.3920.

*b.* From the oxygen point to 0 °C, the temperature  $t$  is defined by the formula

$$R_t = R_0 [1 + At + Bt^2 + C(t - t_{100})^3],$$

where  $R_0$ ,  $A$ , and  $B$  are determined in the same manner as in *a* above, the constant  $C$  is to be determined from the value of  $R_t$  at the oxygen point, and  $t_{100} = 100$  °C.

*c.* From 630.5 °C to the gold point the temperature  $t$  is defined by the formula

$$E = a + bt + ct^2,$$

where  $E$  is the electromotive force of a standard thermocouple of platinum and platinum-rhodium alloy, when one of the junctions is at 0 °C and the other at the temperature  $t$ . The constants  $a$ ,  $b$ , and  $c$  are to be determined from the values of  $E$  at 630.5 °C, at the silver point, and at the gold point. The value of the electromotive force at 630.5 °C is to be determined by measuring this temperature with a standard resistance thermometer.

The wires of the standard thermocouple shall be annealed and the purity of the platinum wire shall be such that the ratio  $R_{100}/R_0$  is not less than 1.3920. The platinum-rhodium wire shall consist nominally of 90 percent platinum and 10 percent rhodium by weight. When one junction of the thermocouple is at 0 °C and the other is successively at 630.5 °C, the silver point, and the gold point, the completed thermocouple shall have electromotive forces such that

$$E_{Au} = 10\,300\,\mu\text{V} \pm 50\,\mu\text{V}$$

$$E_{Au} - E_{Ag} = 1183\,\mu\text{V} + 0.158 (E_{Au} - 10\,300\,\mu\text{V}) \pm 4\,\mu\text{V}$$

$$E_{Au} - E_{630.5} = 4766\,\mu\text{V} + 0.631 (E_{Au} - 10\,300\,\mu\text{V}) \pm 8\,\mu\text{V}.$$

*d.* Above the gold point the temperature  $t$  is defined by the formula

$$\frac{J_t}{J_{Au}} = \frac{\exp \left[ \frac{C_2}{\lambda(t_{Au} + T_0)} \right] - 1}{\exp \left[ \frac{C_2}{\lambda(t + T_0)} \right] - 1},$$

where  $J_t$  and  $J_{Au}$  are the radiant energies per unit wavelength interval at wavelength  $\lambda$ , emitted per unit time per unit solid angle per unit area of a blackbody at the temperature  $t$  and the gold point respectively,  $C_2$  is the second radiation constant with the value  $C_2 = 0.014\,38$  meter-degrees,  $\lambda$  is in meters, and  $T_0 = 273.15$  degrees.

Recommendations for experimentally realizing the above-defined scale also may be found in Stimson's translation.

Until 1948 the thermodynamic scale was defined on the basis of the 100-degree temperature interval between the ice and steam points. Lord Kelvin, who originally defined the scale in this manner in 1854, recommended that when a single fixed point was sufficiently well known it would be preferable to define the scale using this one point. In 1948 the ninth general conference redefined the thermodynamic scale in this way using the triple point of water and in 1954 the 10th general conference approved the

value of  $273.16^\circ \text{K}$  for this point. The zero of the thermodynamic Celsius scale is still the freezing point of water but defined to be .0100 degrees below the triple point. The International Practical Temperature Scale of 1948 is not defined below the boiling point of oxygen. In the temperature range from the oxygen point to the ice point, measurements in 1932 and in 1935 indicated that the two scales agreed within  $0.05^\circ$ . A determination of the thermodynamic temperature of the oxygen point in 1953 gave  $-182.94^\circ \text{C}$ . Intercomparison of two nitrogen gas thermometers with platinum resistance thermometers between the ice and sulfur points indicated that the thermodynamic scale was about  $0.006^\circ$  lower at the steam point and  $0.1^\circ$  higher at the sulfur point than the practical scale of 1948. A redetermination of the gold point utilizing gas thermometry was reported in 1961 as  $1,064.5^\circ \text{C}$ . In 1956 the same method had given a value of  $1,063.69^\circ \text{C}$  for the gold point and  $961.28^\circ \text{C}$  for the silver point. Above the gold point, differences between the fundamental and practical scales can be estimated from estimates of the difference between defined and true values of  $t_{\text{Au}}$ ,  $c_2$ , and  $T_0$ . The uncertainty in  $T_0$  can be neglected compared with that of  $t_{\text{Au}}$ . An analysis of variance of data on atomic constants in 1955 gave the value of  $1.43888 \text{ cm. degree}$  for  $c_2$ ; and in 1957 similar analysis gave it as  $1.43886 \text{ cm. degree}$ . If the correct value for  $c_2$  were  $1.439$  and  $t_{\text{Au}}$  were  $1,064^\circ \text{C}$ , the thermodynamic temperature above the gold point would be about  $0.07\%$  higher than that of the practical scale of 1948.

**2. Gas Thermometry.**—Modern industrial gas thermometry

is limited because of the difficulty of correcting for the expansion of the gas in the connecting tube between the bulb and the pressure measuring device, such as the Bourdon tube, or pressure spring. However, scientific interest in precise gas thermometry has been directed to gases such as nitrogen, hydrogen, and helium (fig. 3), and to converting the real gas thermometer scale to the thermodynamic scale (which would be realized by an ideal gas). Gas thermometry is basic in the accurate definition of physical units ( $q.v.$ ), the relation of the universal gas constant  $R$  (in the equation of a perfect gas  $pV = RT$ ) to many other constants, and through the dependence of these constants on the value of the ice point  $T_0$  on the Kelvin or thermodynamic scale.

General thermodynamic theory of empirical departures from the laws of an ideal gas indicates  $pV = RT + Bp$  for moderate pressures (one or two atmospheres). For the three commonly used thermometric gases mentioned above, the term  $Bp$  amounts to less than  $0.1\%$  of  $RT$  at  $0^\circ \text{C}$  and one atmosphere.  $B$ , the second virial coefficient, is a function of both temperature and pressure, but because  $Bp$  is so small,  $B$  values may be determined with satisfactory accuracy by varying  $pV$  at constant temperature and writing  $B = v - RT/p$ . The slopes of the  $pV$  isotherms of any gas serve in themselves to determine the departure of the gas from ideal, without the use of any other data. Some investigators set up equations for  $B$  as a function of  $T$  and use them to smooth the data.  $B$  values can also be calculated from the Joule-Thompson coefficient  $\mu$ , and the specific heat  $C_p$  at constant pressure. Most

FIG. 3.—EXPERIMENTAL GAS-THERMOMETER SYSTEM CONSTRUCTED IN DUPLICATE

The three pressure systems are designed for operating the nitrogen-filled thermometers at constant volume: (1) the main system, B, A', (F), D, G, H, J; (2) the auxiliary system, A, C, P, M, Q, for determining the correction for the dead space, the region of large thermal gradient; and (3) the external pressure adjusting system, steel case to E to N. Mercury reservoirs L are connected through steel blocks H and M to the manometers G, J and P, Q. Bulb is of vitreous silica and connections are steel capillaries and stopcocks. K is a thermostated housing

of the data on gas scale corrections are, however, based on the compressibility, the  $pV$  isotherms. In the 1960s, the U.S. National Bureau of Standards had a precise gas thermometry program aimed at realizing the thermodynamic scale from the triple point to the gold point with greater accuracy than any previous work. A 0.01-degree accuracy at the gold point appeared to be attainable. Significant results were expected that would alter the practical scale to better agree with the thermodynamic scale.

**3. Modern Mercury-in-Glass Thermometry.**—By far the most important in point of numbers used, the mercury thermometer lost its standing as a primary standard to the platinum resistance thermometer, despite its high potential for accuracy. Particularly in the range from slightly above  $-40^{\circ}$  to  $150^{\circ}$  C, accuracies near  $0.01^{\circ}$  are attainable in experienced hands. A thermometer of such a grade has its scale etched directly on the glass stem. The thermal volume expansion of mercury is only about 180 parts per 1,000,000 per  $^{\circ}$ C at room temperature, yet an accuracy of indicating an expansion of only 180 parts in 100,000,000 is attainable. It is especially remarkable in view of the natural instability of glass, even of the special hard glasses employed. Such an accuracy is obtained only under carefully prescribed conditions. The thermometer must have been properly annealed, filled with the purest mercury, and sealed with the correct pressure of nitrogen in the capillary space; *i.e.*, just sufficient to prevent the mercury from easily separating during rough handling. Some manufacturers age their thermometers for extended periods at as high a temperature as they can withstand after filling and sealing. This is supposedly an inferior method.

Calibration must proceed at a series of successively higher temperatures, must include the ice point, and must be carried out with mercury in the stem extending out of the hot bath only far enough to be seen. When the thermometer is used, measurements must be made under a similar set of conditions. If a thermometer thus calibrated is heated after having been, for instance, at the ice point for several days, the bulb will expand within a few minutes to the size it had at this higher temperature during calibration. If it then is cooled back to zero the bulb will gradually shrink to its original size over several days. During this period the bulb is larger than normal, producing an error called the ice-point depression in even the best thermometers. The depression at any temperature amounts to nearly  $0.01^{\circ}$  for every 10-degree drop if the observation is made within a few minutes of cooling. Thus it would require a thermometer graduated in tenths of a degree to reveal this hysteresis (or lag) readily.

The device just described is known as a total-immersion thermometer. It is normally used and calibrated with all its mercury immersed except the bit required to be visible outside the bath. If it is used with a considerable part of the capillary thread of mercury extending out of the bath, the stem correction is about  $0.00016n(T - t)$  where  $n$  is the number of  $^{\circ}$ C emergent from the bath,  $T$  is the temperature in  $^{\circ}$ C of the bath, and  $t$  is the average temperature of the emergent stem. Partial-immersion thermometers, the commoner form for industrial use, do not have a single stem-correction formula, since the conditions under which they are calibrated vary.

The upper limit of temperature for which these thermometers can be designed depends not only upon the softening range of the glass but also upon the high vapour pressure of mercury. The commonest glasses made expressly for thermometers permit reliable use up to about  $400^{\circ}$  C ( $752^{\circ}$  F). Those glasses usually contain lead, and the harder borosilicate glasses raise the limit to about  $500^{\circ}$  C ( $932^{\circ}$  F). Still harder glasses which raise the limit to about  $650^{\circ}$  C ( $1,202^{\circ}$  F) are used to some extent, but suffer the competition of thermocouples.

High-temperature thermometers have been made of fused silica filled with the metal gallium which melts at approximately  $30^{\circ}$  C ( $86^{\circ}$  F) and boils above  $1,600^{\circ}$  C. The lower vapour pressure of the liquid gallium at high temperatures is a real advantage, but capillary tubes of fused silica are difficult to make because of the high melting point ( $1,710^{\circ}$  C) of this oxide, and the combination has not been extensively employed. The lower limit of mercury-in-glass thermometers has been extended by alloying thal-

lium with the mercury in a percentage close to the composition having the lowest melting point (eutectic mixture). This is at 9.3% thallium, the melting point being  $-59^{\circ}$  C ( $-74^{\circ}$  F). Such a thermometer is easier to make than the gallium-in-silica, and has been used in limited quantities.

**Thermometric Lag.**—When a thermometer is immersed in a fluid medium, the thermometer temperature changes rapidly at first and more slowly as that of the medium is approached. When no further change of the thermometer can be detected it is assumed that the temperature of the medium is indicated. If the temperature of the medium is varying, the thermometer will be at a temperature that is lower or higher than that of the medium at any given moment as a function of this lag. A mercury-in-glass thermometer, when immersed bare in a stirred bath, lags the temperature of the bath according to Newton's law. In this case the rate of change of temperature of the thermometer is proportional to the difference between its temperature and that of the bath. As given by D. R. Harper:

$$\frac{d\theta}{dt} = \frac{1}{\lambda}(u - \theta)$$

where  $u$  is the temperature of the bath at time  $t$ ,  $\theta$  is the temperature of the thermometer at the same time, and  $\lambda$  is a constant.

In the case of constant temperature in a stirred bath, the solution is:

$$(\theta - u) = (\theta_0 - u)e^{-t/\lambda}$$

where  $e$  is approximately 2.718, and  $\theta_0$  is the temperature at the start of reckoning time ( $t = 0$ ). At the time  $t = \lambda$ ,  $(\theta - u) = (\theta_0 - u)/e = .37(\theta_0 - u)$ ; *i.e.*,  $\lambda$  is the time required for the temperature difference to be reduced to 37% of the initial difference. This value of  $\lambda$  is called the time constant (lag constant) of the thermometer under the conditions of the bath. An ordinary bare laboratory thermometer has a time constant of 2 to 3 seconds in a well-stirred water bath, 5 or 6 seconds in oil, and about 1 minute in well-stirred air; it is 3 or more minutes in still air. The time required for the difference to decrease to 1% of the initial difference is  $4.6\lambda$  and the time to reach 0.1% is  $6.9\lambda$ . For example, a bare thermometer for which  $\lambda$  is 2 seconds, when immersed in a stirred water bath which is  $10^{\circ}$  hotter than the thermometer, will warm  $6.3^{\circ}$  in 2 seconds,  $9.9^{\circ}$  in 9.2 seconds, and  $9.99^{\circ}$  in 13.8 seconds.

These simple relations do not apply to thermometers in a sheath or to other cases where more than one layer of substance is found between the bath and the mercury.

**Liquid-in-Glass Thermometers** other than mercury-filled are employed to a considerable extent for temperatures below the freezing point of mercury. The (ethyl) alcohol thermometer is used from  $70^{\circ}$  to  $-80^{\circ}$  C. Many organic liquids can be used, the special requirements being low freezing point, low viscosity, non-toxicity, and ability to dissolve a dye while remaining stable. Pentane thermometers are useful from  $30^{\circ}$  to approximately  $-200^{\circ}$  C and toluene thermometers are useful from  $150^{\circ}$  to  $-80^{\circ}$  C. Most organic liquids have an expansion coefficient many times larger than that of mercury; these so-called spirit thermometers are characterized by a large diameter of the capillary and superior visibility of the red-dyed column of liquid. The liquids tend to form separate droplets that are readily rejoined by tapping the stem. Because these liquids all wet the glass, forming a deep meniscus, the top of the column is not so accurately observable as that of a mercury column. Also, during a decrease of temperature, the receding liquid leaves a thin film on the glass, which runs down slowly. While this distributed liquid is running down, the thermometer indicates too low a temperature. In spite of these disadvantages such thermometers are widely used. Before sealing the top of these thermometers after filling, the bulb is cooled with dry ice and the space above the liquid is left full of air, which materially reduces distillation into the space and separation of the liquid column.

**4. Modern Dial Thermometers.**—Modern dial thermometers have industrial importance rivaled only by mercury-in-glass in point of numbers. Though there are many types including solid,

liquid, gas, or liquid-vapour filled, this article will discuss only the liquid-filled. The usual liquid is mercury because of its range of usefulness from  $-40^{\circ}$  to somewhat above  $500^{\circ}$  C. Most of the mercury is contained in a strong steel (sometimes stainless) bulb to which is welded a long steel capillary tube having a bore about .01 in. in diameter. The other end of the tube is welded to a Bourdon tube, sometimes called a pressure spring, also of steel, mounted in a case and attached through a mechanism to a rotating pointer. The entire closed system of bulb, tube, and flattened pressure spring which has been wound into a spiral or helix, is filled with mercury (to the exclusion of any gas or low-boiling liquid) under a pressure of a few hundred pounds at room temperature. Higher temperatures increase this pressure so that it is maintained well above the vapour pressure of the mercury, while not exceeding the limited strength of the pressure spring, which is highly strained as the liquid expands. With a proper connecting mechanism, the scale of such a thermometer is very nearly uniform. In its more highly developed form the expansion of the mercury in the tube and spring is compensated so that tubes more than 250 ft. long can be used without material loss of accuracy.

One form of compensating device consists of a duplicate capillary tube, also containing mercury, and attached to a second pressure spring that opposes the main spring; another consists of a wire of nickel steel threaded through the single tube. This wire is selected to have a negligible expansion (e.g., invar) and the space between it and the wall of the capillary bore is adjusted to vary with temperature in correspondence with the expansion of the mercury. A bimetallic spring can be used to separately compensate for the expansion of the liquid in the pressure spring. Such thermometers, especially with the connecting tube protected with an armour of flexible metal or rubber, successfully compete with electrical thermometers and are also made into recorders and automatic controllers of various forms. Organic liquids are occasionally substituted, but their higher expansions are offset by the necessity of keeping the volume of the bore and spring small compared with that of the bulb. Furthermore, none of them have a range comparing favourably with that of mercury.

**5. Electrical Thermometry.**—This is intended to include resistance and thermoelectric instruments; that is, those in which a resistor or a thermocouple is used.

The resistance thermometer affords the greatest precision of all forms of temperature-measuring devices in ranges below  $660^{\circ}$  C, and is widely used in scientific and industrial laboratories. It is made in rugged and less expensive forms for measuring the temperatures of manufacturing processes, machines, stationary structures, air-conditioning equipment, and other applications where temperatures do not exceed about  $150^{\circ}$  C ( $302^{\circ}$  F). Most industrial forms employ a resistor of nickel wire (occasionally copper) in a helix or coil and protected in a sealed metal tube. For higher temperatures platinum is used because nickel undergoes a molecular transformation between  $300^{\circ}$  and  $350^{\circ}$  C, accompanied by troublesome changes in resistance with rising and falling temperatures; also it is not available in high purity, and cannot be annealed satisfactorily after winding in the form of insulated wire. Platinum can readily be obtained with a purity better than 99.999%, and for industrial use thermometers made of such metal do not require annealing at a high temperature to reproduce a standard resistance-temperature relation.

Platinum resistance thermometers in strain-free form and mounted in glass or quartz tubes filled with air, nitrogen, or helium for small lag, display stability of resistance to temperatures as high as  $700^{\circ}$  C. Slow changes of resistance of a few parts per 1,000,000 can be detected, however, during long continued use, and proper corrections to a few parts in 10,000,000 are on occasion reliably applied. These thermometers have four leads usually made of gold wire, extending from the coil to the head. Short lengths (an inch or so) of platinum wire connect the gold to the resistor to reduce the heat conduction to the leads. A convenient value of the resistance for most purposes is 25.5 ohms such that the variation is approximately 0.1 ohm per degree centigrade. By the 1960s platinum resistance measurements had been made with a stability and reproducibility at the gold point at least ten times greater than was

possible with the standard thermocouple. A platinum resistance thermometer was expected to replace the thermocouple on the International Practical Temperature Scale.

The expression  $R_t = R_0(1 + At + Bt^2)$  for the relation between resistance and temperature for platinum, as found above in the definition of the international practical scale gives the same set of resistance-temperature values as the original Callendar formula:

$$t = \frac{R_t - R_0}{R_{100} - R_0} (100) + \delta \left( \frac{t}{100} - 1 \right) \frac{t}{100}$$

both being empirical formulas in the first power of  $R_t$  and the first and second power of  $t$ .

Modern methods of measuring resistance are fundamentally the same as those described above. A gold-chromium alloy provides coils with resistances that are reported to change by no more than 1 or 2 parts in 1,000,000 within the ordinary range of room temperatures. Resistors of this alloy can be made of very fine wire and are especially suited for standards of reference. It is doubtful that they will replace thermostated manganin in resistance-measuring bridges. However, since an entire bridge can be rechecked with a single reference standard, this alloy can improve the reliability of measurements.

Except possibly at temperatures above  $1,500^{\circ}$  C very little more is expected to be done to significantly improve thermocouples or their use. They continue to attract wide interest since they offer such advantages as simplicity, low cost, a wide range, ease of installation, and small size. The major limitation is the effect on the temperature determination when any physical or chemical inhomogeneity in the thermocouple leads exists in a temperature gradient. With the purest platinum and platinum-rhodium available in the 1960s an accuracy of  $\pm 0.1^{\circ}$  was difficult to achieve. However, when  $\pm 0.1^{\circ}$  is adequate below  $500^{\circ}$  C and  $\pm 0.3^{\circ}$  above  $500^{\circ}$  C, the thermocouple is an excellent temperature-measuring instrument; between  $630^{\circ}$  and  $1,063^{\circ}$  C it remained the international standard thermometer.

The thermocouples in common use are limited to those made of a relatively few combinations of metals found to have such characteristics as an emf increasing continuously with rising temperature over a considerable range; freedom from significant change of emf by changes of crystalline structure; resistance to oxidation, corrosion, or contamination. Among the best combinations are platinum with platinum-10% rhodium (also 13%); copper with constantan; iron with constantan; and chromel *P* with alumel. The combination of chromel *P* with constantan is occasionally used because of a relatively large emf. The platinum combinations are useful from  $0^{\circ}$  to nearly  $1,500^{\circ}$  for extended exposures and in the combination platinum-6% rhodium with platinum-30% rhodium to  $1,700^{\circ}$  C. A few refractory metal thermocouples have been used successfully up to  $2,000^{\circ}$  or  $2,200^{\circ}$  C. These include tungsten with rhenium, tungsten with tungsten-2.6% rhenium, and iridium with a rhodium-iridium alloy, usually 40% to 60% iridium. Corresponding temperatures for copper-constantan are  $-200^{\circ}$  to  $350^{\circ}$  (max.  $1,000^{\circ}$ ); for iron-constantan,  $-200^{\circ}$  to  $750^{\circ}$  (max.  $1,000^{\circ}$ ); for chromel-alumel,  $-200^{\circ}$  to  $1,200^{\circ}$  (max.  $1,350^{\circ}$ ). The nominal composition of constantan, which is also used in larger quantities for resistor wire, is 55% copper and 45% nickel. Chromel, identified as chromel *P* to distinguish it from electrical heating wire, has retained its original composition of 90% nickel with 10% chromium, but alumel is 95% nickel with aluminum, silicon, and manganese added.

The platinum, platinum-rhodium thermocouple invented by Le Châtelier is noted for its stability and freedom from internal changes. It is usually used carefully protected in a refractory porcelain insulator and tube. The metals of which this couple is made have a purity of the highest order, spectroscopic analysis revealing scarcely the slightest trace of impurity. This cannot be said of any of the other metals employed for thermocouples although the copper generally used is so pure as to require the spectroscope to detect slight traces of iron, silicon, and dissolved oxygen. While platinum of the purity found in resistance thermometer and thermocouple wire is the primary thermoelectric ref-

erence standard, the best grade of commercial copper wire makes an excellent standard that can be relied upon to a few microvolts for a 200° C interval.

The copper-constantan thermocouple is noted for its well-established temperature emf relation from about -260° to 350° C, its low cost, and the not inconsiderable adaptability to the use of long extension leads of the same composition and relatively low resistance. Also, as compared with iron, copper oxidizes very slowly at ordinary temperatures at which iron must be protected from rusting. The iron-constantan couple is the most widely used in industrial applications because it is inexpensive and has a useful range well above that of copper.

The chromel-alumel couple is well known for its outstanding resistance to oxidation at high temperatures, especially in the range from 750° to 1,200° C, where it is most often used. It must not be exposed to reducing gases; oxidized chromel exposed to hydrogen, for example, develops a conducting coating of nickel mixed with chromium oxides. The widespread employment of controlled atmospheres in heat-treating furnaces of the metals industries accentuates this limitation on the chromium-alloy couple.

Probably the most serious limitation in using thermocouples above about 1,800° C is the lack of an adequate insulating material. Alumina is excellent but cannot be used above about 1,800° C. Beryllia and thoria have been used with some success to about 2,200° C but nothing is available above this temperature.

The relations between temperatures and emf for thermocouples are based on experimental data, not on any theoretical relation. In a simple thermoelectric circuit of two metals joined into a closed loop, emf arises at each junction and in each leg of the couple where it passes through the temperature gradient (*see THERMOELECTRICITY*). Analytical expressions have been set up for the platinum, platinum-10% rhodium thermocouple and the copper-constantan couple but these are applicable over limited ranges. For example, the expression  $E = a + bt + ct^2$  is used in the specifications for reproducing the international scale between 630.5° and 1,063° C with the former couple, and the equation  $E = at + b(1 - e^{ct})$  has been used between 0° and 350° C for the latter couple. The expressions are useful for construction of tables from which deviation curves or tables can be constructed for particular calibrated couples. The temperature-emf tables for iron-constantan and chromel-alumel couples reveal that no expression as simple as those given above would suffice even as a rough approximation. If a couple is expected to furnish measurements agreeing with the international scale, it must be calibrated with a platinum resistance thermometer from -190° to 630.5° C, with a platinum, platinum-10% rhodium couple from 630.5° to 1,063° C, and with a proper radiation device above 1,063° C.

Modern electrical instruments for use with thermocouples can be classified as millivoltmeters and potentiometers (fig. 4). Industrial potentiometers are built

around a resistor with sliding contact (slide wire); precision potentiometers have three or more dial switches for connecting between fixed resistors, after the manner of the precision bridge. Recording potentiometers almost completely removed recording millivoltmeters from the industrial scene. Industrial instruments have extraordinary precision considering the severe requirements for ruggedness and reliability. Industrial recording to 1° F is not uncommon, and automatic control of some processes to 0.1° has been attained.

**6. Modern Optical Pyrometry.**—The disappearing-filament pyrometer continues to afford the greatest precision and accuracy for research work and

the greatest convenience for practical applications in optical pyrometry. The principal commercial forms are made by the Leeds and Northrup Co. and the Pyrometer Instrument Co. in the U.S., their optical principles being similar to those of the laboratory type. The Leeds and Northrup device is portable, with a unique type of slide-wire potentiometer designed for rapid use. The lamps in these instruments are highly evacuated so that the tungsten wire or ribbon will withstand heating to 1,500° C for hundreds of hours without serious change. Gas filling would reduce the rate of evaporation of tungsten, but the lamp would become subject to changes in ambient temperature, and introduce great lag in its response to adjustments in the heating current. Fairly high temperatures can be measured without heating the lamp much above 1,400° C by the use of absorption screens, and the lamp will retain its original calibration remarkably well for many years.

Such pyrometers are calibrated at national laboratories by comparison with a standard instrument or by sighting them on large tungsten-strip lamps that previously have been calibrated. Primary calibrations at the gold point are made by sighting the pyrometer at a black body immersed in highly pure freezing gold. Calibrations below or above the gold point are made by sighting at a convenient source (this need not be a black body) with a calibrated screen interposed. This screen may be a rotating disk with an open sector that has been measured on a circular dividing engine, or an absorbing coloured glass whose transmission has been measured by comparison with a sector disk or with the interval between two fixed points. Primary calibrations above the gold point are based on this one point (1,063° C) and the constant  $c_2$  in the Planck equation. A complete table of temperature-current values is tediously built up by smoothing the deviations from a reference table or curve based on an equation such as  $i$  (current) =  $a + bt + ct^2 + dt^3$ , the four constants of which are determined from four selected calibration points. The interval from the copper point to the palladium point is so large that it is preferable to establish at least two points in between with sector disks or absorption screens to step down from the upper point. The most accurate measurements above the gold point are obtained by keeping the pyrometer lamp at a current value nearly corresponding with that determined for the gold point, and choosing an absorption device to nearly fit the extrapolation desired, for example, from gold to the platinum point (1,769° C). For much higher temperatures the lamp has to be raised toward the palladium point to make use of screens of accurately measurable transmission.

Laboratory pyrometers (Fairchild type) can be calibrated with respect to the international scale to about 0.4° at the gold point and about 3° at 2,300° C. High temperatures are readily measured with the disappearing-filament pyrometer without overheating the lamp by using two absorbing screens or one combined with a sector disk. For brightness temperatures up to about 2,500° C tungsten-strip lamps can be calibrated and used as transfer standards with an accuracy from about  $\pm 3^\circ$  at the gold point to  $10^\circ$  at 2,500° C. An interesting fixed point for high-temperature work is that of the positive crater of the carbon arc. With a properly operated electric arc and a positive electrode of pure graphite, the apparent temperature, usually called brightness temperature, is about 3,800° K with an uncertainty of approximately 15°.

Some success was attained by the 1960s with photoelectric devices to take the place of the optical pyrometer. One photoelectric pyrometer developed at U.S. National Bureau of Standards used a photomultiplier tube as a detector and a multilayer interference filter to restrict the spectral band. A small tungsten lamp in the device is moved in and out of the optical path at thirty second intervals, permitting the detector to compare the brightness of the unknown source with that of the known lamp. The instrument has a sensitivity and a short-term reproducibility of about 0.02° C, but the instability of the lamp limits the long term reproducibility to about 0.1° C at 1,063° C. Accuracy of this photoelectric pyrometer was expected to be about four times greater than the best visual pyrometer. In addition the instrument affords a potential means for automatic recording and making brightness measurements of sources having a short time duration. Several commer-

FIG. 4.—A SIMPLIFIED DIAGRAM OF THE ELECTRICAL CIRCUIT OF A POTENTIOMETER FOR USE WITH A THERMOCOUPLE

BY COURTESY OF LEEDS AND NORTHRUP CO.

dial photoelectric pyrometers were also available in the 1960s.

Many forms of so-called colour pyrometer have been invented from time to time. In these instruments the intensities of radiation of two bands of wavelengths are compared and interpreted by calibration, as corresponding to some temperature. Commercial two-colour devices available in the 1960s were not as sensitive as the photoelectric (single-colour) type and were of little value in accurate work.

**7. Modern Radiation Pyrometry.**—This is pyrometry in which heat radiation of a broad wavelength region is used as a measure of temperature, is generally confined to industrial applications and seldom employed in research work. Relatively useful designs for the ceramic and steel industries lack the precision of the optical pyrometer, and are generally set in a fixed position where they can be checked with an optical instrument. These pyrometers are constructed of a receiver of heat radiation consisting of a thermocouple junction or small group of junctions, mounted in a housing (fig. 5) that can be water-cooled if necessary, and in which reference junctions of the couples are disposed as to give the least errors from variations in the temperature of the whole receiver. Such instruments are especially valuable where recorded temperatures are essential, where immersed thermocouples cannot withstand the heat, or corrosive vapours of gases, or where the cost of a photoelectric pyrometer is prohibitive. The

practice of attaching the receiver of these instruments to the open end of a tube inserted into a furnace protects the receiver from flame and smoke, and permits sighting it through an atmosphere free from carbon dioxide and water vapour, gases that are not transparent to infrared radiation. The thermal lag introduced by the thick-walled tube is not a deterrent to this practice where the lag of the furnace itself is large.

**8. Flame Thermometry.**—The measurement of temperatures in flames or hot gases, particularly above  $1,500^{\circ}\text{K}$ , requires equipment or techniques somewhat different from those already considered. Thermocouples or resistance thermometers are generally not used in such flames because of serious radiation losses, disturbance of the combustion process, mechanical rigidity of the thermometer, and melting of the thermometer itself. An optical pyrometer or two-colour pyrometer can sometimes be used, but usually the emissivity is unknown or changing rapidly with wavelength, producing large uncertainties in their application. Two of the more widely used methods are those of line reversal and of intensity distribution in spectral lines.

In the line-reversal method, the brightness of a source of radiation, such as a tungsten-strip lamp, is adjusted until at a wavelength corresponding to some spectrum line in the flame, the source appears equally bright when viewed directly or through the flame. The flame temperature is the temperature of a black body having this brightness; i.e., the brightness temperature of the source at

the same wavelength. This method is based on Kirchhoff's law, which states that the fractional amount of radiation absorbed by a body is equal to the fraction it emits relative to a black body at the same temperature. Thus when the black body and the flame are at the same temperature, the amount of radiation absorbed by the flame is just equal to that which it emits and the black body appears equally bright when viewed directly or through the flame. Usually a spectrograph or a monochromator equipped with a suitable detector such as a photomultiplier is used to isolate and measure the radiation at the spectrum line. An element not found in the flame may be added to obtain a strong spectrum line in a convenient spectral region. Sodium, which emits strong yellow lines at 5890 and 5896 Å, has been used frequently.

It is possible to obtain reversal temperatures at  $2,500^{\circ}\text{K}$  that are reproducible to a few degrees. However, it is very questionable that the temperature measurement is this accurate. Great care must be taken with the optical path, the solid angles subtended and corrections for optical elements utilized with the tungsten source only. In addition, the brightness temperature of the tungsten source will be uncertain by at least  $7^{\circ}$  at  $2,500^{\circ}\text{K}$  and greater at higher temperatures; temperature gradients in the flame will also affect accuracy. Nevertheless, the reversal method is probably more reproducible than any other method known in the 1960s for measuring flame temperatures; in many cases, the measured temperature agrees reasonably well with that calculated from known equilibrium concentrations.

A second method for determining flame temperatures is based on the relative amount of energy emitted by a source per unit time (relative intensity) in two or more spectral lines. According to quantum theory (see PHYSICS: GENERAL SURVEY; QUANTUM MECHANICS) an atom or molecule can have only certain definite energies that are called energy levels. An atom in a flame, for example, can lose its excess energy by making a transition to a lower energy level. There is a definite probability that this lost energy will appear in the form of radiation. This radiation will have a particular wavelength (spectral line) that is inversely proportional to the lost energy. For a source containing many atoms, the intensity of a spectral line is the product of the energy for one transition, the number of atoms in the initial energy level, and the probability of the transition. The relative number of atoms in two or more known energy levels for a system in thermal equilibrium depends only on the temperature; and therefore the temperature can be calculated if the relative number of atoms is known. Thus if the energy levels and the relative transition probabilities can be calculated or determined in an independent experiment, the relative intensity of two or more spectral lines emitted by a source in thermal equilibrium can be used to obtain the temperature of the source. Spectroscopists have determined many energy levels for a great number of atoms and molecules. Unfortunately, as of the 1960s only a few relative transition probabilities had been determined experimentally or could be calculated accurately. This has been one of the major limitations of this method of measuring flame temperatures. It has the advantage over the reversal method in that another source is not viewed through the flame, thereby making the optical setup less critical.

**9. Thermometry Below the Oxygen Point.**—The international scale was not yet defined below the boiling point of oxygen by the 1960s. None of the thermometers available for low-temperature measurements had the characteristics of a practical standard—sensitivity, reproducibility, convenience, and a simple interpolation equation.

From  $90^{\circ}$  to  $20^{\circ}\text{K}$  the platinum resistance thermometer was still the most precise thermometer available. Below  $50^{\circ}\text{K}$  its sensitivity begins to decrease rapidly but at  $17^{\circ}\text{K}$  it still has sufficient sensitivity to determine differences of  $0.001^{\circ}$  or less. At  $11^{\circ}\text{K}$  the sensitivity has decreased by a factor of about 4 relative to that at  $17^{\circ}\text{K}$ . The major limitation was that no simple mathematical relationship had been found between temperature and resistance. The suggestion was being studied that an empirical table be developed that could be adjusted for each thermometer utilizing calibration data at several fixed points.

The U.S. National Bureau of Standards calibrated (1965) plati-

num resistance thermometers down to 11° K. This was done by comparison with six platinum resistance thermometers calibrated against a helium gas thermometer with a reported accuracy of  $\pm 0.02^\circ$ . At Pennsylvania State University a similar calibration of resistance thermometers was estimated to agree with the thermodynamic scale within  $\pm 0.005^\circ$ .

When considerably less precision than that available with a platinum resistance thermometer is required, a copper-constantan thermocouple can be used down to about 15° K. Another thermometer that often is useful in this region is the saturation vapour pressure of hydrogen. The vapour pressure-temperature relationship has been determined from the critical point, 33° K, where the pressure is about 9,700 mm. Hg, to the triple point, 13.8° K, where the pressure is about 53 mm. Hg.

Below 11° K platinum resistance thermometers are of little value because of their small sensitivity. However, resistance thermometers made of semiconducting materials have ample sensitivity by virtue of their negative temperature coefficient; i.e., the resistance increases with a decrease in temperature. A major limitation of the semiconducting thermometers has been their lack of stability. However, germanium alloy thermometers containing extremely small amounts of indium have been reported to be reproducible to 0.001° between 1° and 5° K, even after repeated warming and cooling. Even better reproducibility (0.003° at 4.2° K) with germanium resistors (1963) indicated that such devices may become standard thermometers in the range from about 1° to 15° K.

Since in most low-temperature experiments the basic cooling is produced by a bath of liquid helium, the saturation vapour pressure of helium is a convenient thermometer. Its useful range extends from the critical point (5.2° K and 1,718 mm. Hg) to the lowest pressure conveniently measured (0.1 mm. Hg and 1° K). The relationship between the vapour pressure of helium and its temperature led to the adoption (1958) of He<sup>3</sup> as an international standard between 1° and 5.2° K; He<sup>4</sup> was made (1962) an international standard between about 0.3° and 3.5° K (see HELIUM).

Below 0.3° K a major problem is the difficulty in establishing thermal equilibrium. The magnetic thermometer is one of the few devices that can be used. It is based on the fact that the magnetic susceptibility of a paramagnetic salt is a function of temperature. Therefore, if such a salt is placed in the magnetic field of an inductor, the inductance which depends on the susceptibility of the salt can be used as a temperature indicator. Often at temperatures below 1° K, paramagnetic salts themselves are investigated. Thus the unusual but convenient situation is encountered where the material under study, the coolant, cold bath, and thermometer are one and the same. Another feature of the magnetic thermometer is that it is in the class of absolute instruments such as the gas thermometer. With proper corrections, it can be used to determine the ratio of thermodynamic temperatures, but the precision is not very great (see MAGNETISM: Paramagnetism).

**THERMONUCLEAR REACTIONS** are those in which the combination (see FUSION) of atomic nuclei of light elements occurs, producing heavier elements. The process leads to an overall loss of mass, which appears as the kinetic energy of the reaction products. The nuclei are similarly charged, and repel each other; under some conditions energy that overcomes this Coulomb repulsion and prompts the particles to fuse comes from the thermal energy of the particles themselves; hence the term thermonuclear. The energy liberated is so great compared to that supplied to overcome Coulomb repulsion that the reaction can sustain itself (chain reaction) and may be used to generate power. Thermonuclear reactions produce the energy in stars and in the hydrogen bomb. Great interest in such reactions stems from the hope of finding

a practical method of controlled nuclear fusion, providing a relatively cheap and abundant replacement for fossil fuels (coal, oil, and natural gas).

Another nuclear reaction called fission produces energy when a heavy nucleus (an isotope of thorium, uranium, or plutonium) absorbs a neutron, becomes unstable, and splits into two or more fragments (see ATOMIC ENERGY). By the mid-1960s only the fission process had been applied to produce controlled supplies of power. Nuclear fusion has distinct advantages over fission, however: its products are not radioactive and the fuel (deuterium in particular) is abundant and inexpensive. Eight gallons of ordinary water contain about one gram of deuterium, with a cost of extraction of not more than about 30 cents and an energy content (if there were a fusion reactor to burn it) equivalent to 2,500 gallons of gasoline.

Since Coulomb repulsion is so effective in keeping particles apart, reactions of interest for controlled fusion are limited to nuclei with the lowest possible charge: the isotopes of hydrogen (ordinary hydrogen H or H<sup>1</sup>, deuterium D or H<sup>2</sup>, and tritium T or H<sup>3</sup>). The first in a sequence of reactions that produce energy in the sun

(where  $e^+$  is a positron) proceeds with too low a probability for man-made reactors (see STAR: Stellar Structure). However, two DD reactions that occur with roughly equal probability

(where  $n$  is a neutron) are of major interest. The energy release (in million electron volts [Mev]) is given in each equation (see DEUTERIUM AND TRITIUM). A DT reaction involving tritium, the rarest hydrogen isotope, is

The three reactions occur with relatively high probability if the bombarding energy of one particle on another exceeds 50,000 electron volts (50 kev). In the DT reaction, for example, the fusion cross section (i.e., the area over which effective collisions occur) reaches a value of  $5 \times 10^{-24} \text{ cm}^2$  at a bombarding energy of 100 kev.

If the D or DT mixture is to begin reacting (ignite) under its own thermal energy, the temperature must be very high (millions of °K). Under these conditions the fuel will be a plasma (a gas of positively charged nuclei and of electrons). Acting to oppose thermonuclear energy production are various loss mechanisms, the most important of these being radiative. Particle density in plasma is too low to permit equilibrium between matter and radiation; hence, the dominant radiation loss is bremsstrahlung (i.e., energy radiated from the very frequent collisions between the charged particles). The ratio of bremsstrahlung loss to energy production through nuclear reaction is independent of the density of the plasma. The point at which this ratio equals unity determines the ideal ignition temperature of the system; when the plasma is hotter than this ignition temperature, the reaction will be self-sustaining if other losses are negligible. The ignition temperature for the DD reaction is about 400,000,000° K, and for DT it is about 45,000,000° K.

To achieve controlled nuclear fusion the reacting system must be confined; but no known material can remain solid at such temperatures. Thus much talent and money have been devoted to an effort to confine the plasma magnetically. Schemes proposed include confinement by a magnetic field surrounding a current discharge (pinch effect); by magnetic mirrors; by a figure-8 magnetic torus (stellarator); and by a multipole (picket-fence) configuration. Early attempts were plagued by instability (see MAGNETOHYDRODYNAMICS), but research on controlled fusion continued in the U.S. at the Los Alamos Scientific Laboratory, the Lawrence Radiation Laboratory, the Oak Ridge National Laboratory, and Princeton University, and in the United Kingdom, France, and the U.S.S.R. See also COSMOGONY: Origin of Chemical Elements.

(J. R. RE.)

**THERMOPYLAE** ("hot gates"; modern Greek *THERMOPYLAI*), a narrow pass about 4 mi. (6 km.) long, named after its hot springs, which are said to have medicinal properties, lies on the east coast of central Greece between the valley of the Spercheus (Sperkhios) River and the district of Locris. The pass is used by any army following the coast, and the alternative route climbs far inland through Doris. In antiquity the cliffs of Thermopylae were about 50 ft. from the sea and at some points much less; nowadays the accumulation of silt has widened the distance to more than a mile. In 480 B.C. a small Greek force under the Spartan king Leonidas held the pass for three days against a huge Persian army (*see* GRECO-PERSIAN WARS). In 323 Leosthenes occupied it as his base against the Macedonian regent Antipater. In 279 the Greeks delayed Brennus and his Gauls there. Antiochus III of Syria in 191 B.C. fortified the pass against the Roman consul Acilius Glabrio. The Persians, Gauls, and Romans turned the pass by sending detachments of troops inland through the hills (the actual routes are disputed): the pass was too narrow for frontal attacks to succeed against heavily armed infantry.

(N. G. L. H.)

**THERMOSTAT**, a device to regulate automatically the supply of heat to, and consequently to control the temperature of, the air in a space, or of liquids or materials involved in a process. Basically the thermostat consists of two elements, a sensing element and an actuating or control element. The sensing element is sensitive to temperature changes that produce proportional changes in its physical dimensions, volume or electrical resistance. The actuating element translates the action of the sensing element to a proportional movement of the controlling air damper, valve or electric switch.

The principle of thermal expansion of metals, liquids and gases with temperature increase is the basis of the sensing element design for all thermostats except the electronic instrument. The range of temperature change during which the linear expansion bears a constant ratio to the temperature change is limited to approximately 250° F. The following table lists the coefficients of linear expansion for the metals commonly used for thermostatic sensing elements.

*Linear Coefficients of Thermal Expansion per Degree Fahrenheit*

Metal	Coefficient
Aluminum	0.000123
Brass	0.000106
Graphite	0.000044
Copper	0.000093
Quartz	0.000003
Wrought iron	0.000063
Invar steel	0.000005
Silver	0.000105

**Sensing Elements.**—Four types of sensing element are commonly used in commercially produced thermostats. The bi-metal strip consists of two strips of metal having widely different linear coefficients of thermal expansion (*see* table). These strips are fused together and as the temperature increases, the strip bends away from the side having the greater coefficient of linear expansion. In application, one end of the strip is anchored, leaving the other end free to move. The strip may be straight, bent to a radius perpendicular to the long axis of the strip into a U shape or a helical shape, or it may be wound in a spiral whose axis is parallel to the long axis. Selection of shape is governed by the magnitude of movement desired at the free end of the strip. In some types of thermostats the bi-metal sensing element produces enough force to actuate the control directly.

The tube and rod sensing element also is designed to take advantage of the difference in the linear thermal expansion of two metals. It is composed of a tube of metal that has a high coefficient of expansion and a rod of metal that has a low coefficient of expansion. The rod is inserted into the tube and anchored at its closed end. The open end of the tube is anchored and as the length of the tube changes with a change in temperature there is a relative movement of the free end of the rod, the length of which has remained unchanged.

The bellows type of sensing element consists of a volume con-

finied by a diaphragm of cup-shaped, very light metal, or a cylindrical vessel with a corrugated wall spun out of light weight metal. The volume is completely filled with a liquid, a vapour or a gas. In any case, an increase in temperature results in an increase in volume and an increase in axial length of the vessel.

The remote bulb type of sensing element is actually an adaptation of the bellows type. It consists of a bulb attached to the diaphragm, or bellows, by a capillary tube of any desired length, all of which is completely filled with liquid, vapour or gas. The bulb is placed in the region to be controlled and any change in pressure due to a temperature change at the bulb is transferred through the capillary tube to the bellows.

The electronic sensing element consists of a small coil of wire whose resistance changes in a constant ratio with temperature changes.

**Actuating or Control Elements.**—In some types of thermostats using a bi-metal sensing element, the sensing element itself functions as the control element and operates directly an air damper or valve. In other types, the sensing element acts as a pilot to the control element that regulates a supply of external energy in the form of pneumatic energy or electrical energy necessary to operate the air dampers, valves or switches.

The type of control element selected depends upon the type of action. To start or stop a burner or fan, to open or close a damper, a two-position control element is used that simply makes or breaks an electric circuit. The so-called floating control is similar to the two-position control element except that there is a neutral zone midway between the two contacts and that the action is at a constant rate toward either of the on or off positions. When the neutral zone is reached, the action stops until the sensing element makes one contact or the other at which time the action is resumed in the proper direction.

The modulating or proportional control element is piloted by the sensing element pushing a sliding contact over a potentiometer coil that controls the position of a reversible valve or damper motor, there being a motor position for each turn of wire on the potentiometer coil.

The pneumatic powered control element action controls the compressed air pressure in pneumatic air motors attached to dampers and valves. The air pressure causes movement in one direction only and a spring powers the return stroke. The position of the motor is fixed by the air pressure in the control line that is regulated by the control element. The pneumatic thermostats have modulating action that also satisfies a two position requirement.

**Types of Thermostats.**—There are five classified types of thermostats. (1) The room thermostat is mounted in the room that is to be controlled. It may have a sensing element of either the bi-metal, bellows or electronic type, and its control element may be powered by electric or pneumatic energy. (2) An insertion thermostat is mounted on a duct with the control element in the room and the sensing element in the duct. (3) The immersion thermostat is used for the control of high pressure fluids or gases. A pressure tight bushing permits the sensing element to be immersed in the fluid and the control element to be accessible. Immersion and insertion thermostats use the bi-metal control element, either the spiral wound or the tube and rod type. The self-contained direct acting tube and rod thermostat is often used to control the water temperature in gas fired water heaters. The rod is linked directly to the gas valve operating mechanism. (4) The surface type thermostat has its sensing element clamped to the surface of a tank or pipe and is an expedient substitute for an insertion or immersion thermostat. (5) The remote bulb thermostat is applied when it is desired to have the control element located at a distance from the sensing element.

**Action of Thermostats in the Control of Residential Heating.**—The action starts with the room thermostat, usually located in the living room. The secondary circuit is normally open, but the thermostat closes the circuit on a falling temperature, causing the relay to close and energize the primary (line voltage) circuit that starts the burner. When the temperature at the room thermostat rises to the desired degree at which it has

been set, the secondary circuit is opened, the relay opens the primary circuit and the burner stops. Thus the room thermostat controls the operation of the burner and the source of heat. The point at which the burner starts is usually  $1\frac{1}{2}^{\circ}$  to  $2^{\circ}$  below the point at which it stops. As a safety measure, a limit switch is connected in series with the secondary circuit in order to prevent overheating.

The limit switch, when used with a warm air heating system, is an insertion thermostat that is reverse acting, *i.e.*, opens on a rising temperature and closes on a falling temperature, and has its sensing element in the warm air bonnet of the furnace. Its opening point is usually set about  $5^{\circ}$  above the minimum air temperature required to heat the house. Its opening point is fixed at  $15^{\circ}$  below its opening point. In case the bonnet air temperature reaches the limit, the switch opens the secondary circuit and the burner stops independently of the room thermostat. After the bonnet air cools  $15^{\circ}$  the limit closes and the burner starts again, providing the room thermostat has not been satisfied in the meantime. The warm air circulating fan is controlled by an insertion thermostat in the warm air bonnet of the furnace and is set to start the fan  $5^{\circ}$  above the lowest temperature that will avoid the sensation of drafts in the living room, and to stop the fan  $5^{\circ}$  below the starting point.

With hot water systems, the room thermostat controls the operation of the circulating pump and the burner is controlled by a direct acting immersion thermostat set to open the secondary circuit at the minimum water temperature necessary to heat the house, and to close at about  $10^{\circ}$  to  $15^{\circ}$  below the opening point. When used with hot water heating systems, the limit switch is a direct-acting double-throw immersion thermostat with one pole in series with the primary circuit to the burner and the other in the primary circuit to the circulating pump. The circuit to the burner is normally closed, and the circuit to the circulator is normally open. When the water temperature rises to the set point, the highest temperature for safe operation, the primary circuit to the burner opens and the burner stops; at the same time the primary circuit to the circulating pump closes and it starts independently of any controls on the secondary circuit.

(W. T. MR.)

**THESEUS**, the great hero of Attic legend, was the son of Aegeus, king of Athens, and Aethra, daughter of Pittheus, king of Troezen (in Argolis, in the Peloponnese), or of Poseidon and Aethra. (Aegeus and Poseidon may be one and the same.) The legend relates that Aegeus, being childless, went to Pittheus, who contrived that Aegeus should have intercourse with Aethra, who

in due time brought forth Theseus. On Theseus' reaching manhood, Aethra sent him to Athens to his father. On the journey he encountered many adventures. First he met and slew Periphetes, surnamed Corynetes (Clubman). At the Isthmus of Corinth dwelt Sinis, called the Pine Bender because he killed his victims by tearing them apart between two pine trees; Theseus hoisted the Pine Bender on his own pine tree. Next Theseus dispatched the Crommyonian sow (or boar). Then over a cliff he flung the wicked Sciron, who used to kick his guests into the sea while they were washing his feet. In Eleusis, Theseus wrestled with Cercyon and killed him. Later he slew Procrustes, who fitted all comers to his only bed by lopping or racking them to the right length.

On his arrival in Athens he found his father married to Medea (*q.v.*). Being a witch, she knew Theseus before his father did, and tried to persuade Aegeus to poison his son; but Aegeus recognized him. Theseus was then declared heir to the throne, and the Pallantids—sons of Pallas, Aegeus' brother—who had hoped to succeed the childless king, conspired against him. Theseus crushed the conspiracy. He then attacked the fire-breathing bull of Marathon (brought there as the seventh labour of Hercules) and took it alive to Athens, where he sacrificed it to Apollo Delphinus. Next came the adventure of the Cretan Minotaur, for which *see* MINOS; MINOTAUR.

While Theseus was on his way to Crete, Minos, wishing to learn whether Theseus was really the son of Poseidon, flung his ring into the sea. Theseus dived and brought it up, together with a golden crown, a gift of the sea goddess Amphitrite. On the return voyage from Crete he landed at Delos, and there he and his comrades danced the crane dance, whose complicated movements were meant to imitate the windings of the Labyrinth. In historical times, this dance was still danced by the Delians round the Altar of Horns. Also on the return voyage he abandoned Ariadne (*q.v.*) at Naxos.

Theseus had promised Aegeus that, if he returned successful, he would hoist a white sail in place of the black sail with which the fatal ship bearing the sacrificial victims to the Minotaur always put to sea. But he forgot his promise, and when Aegeus, from the Acropolis at Athens, saw the black sail at sea, he flung himself from the rock and died. Hence, at the festival which commemorated the return of Theseus there was always weeping and lamentation. Theseus now carried out the union of the various Attic communities into a single state and extended the territory of Attica to the Isthmus of Corinth (*see* ATTICA). He transformed the Isthmian Games (*see* GAMES, CLASSICAL) in honour of Melicertes by adding games in honour of Poseidon. Alone, or with Hercules, he captured the Amazon princess Antiope (or Hippolyta). As a result the Amazons attacked Athens, and Hippolyta fell fighting on the side of Theseus. By her he had a son, Hippolytus, beloved of Theseus' second wife, Phaedra (*see* HIPPOLYTUS). Theseus is also said to have taken part in the Argonautic expedition and the Calydonian boar hunt. He compelled the Thebans to give up for burial the unburied bodies of the Seven (*see* SEVEN AGAINST THEBES).

The famous friendship between Theseus and Pirithous, king of the Lapiths, originated when Pirithous heard of the strength and courage of Theseus and desired to put them to the test. Accordingly, he drove away from Marathon some cows that belonged to Theseus. The latter pursued, but when he came up with the robber the two heroes were so filled with admiration of each other that they swore brotherhood. At the marriage of Pirithous, Theseus participated in the famous fight between the Lapiths and Centaurs. Pirithous now helped Theseus to carry off Helen (*q.v.*). In exchange, Theseus descended to the lower world with Pirithous, to help his friend carry off Persephone. But the two were caught and confined in Hades till Hercules came and released Theseus.

When Theseus returned to Athens, he found that a sedition had been stirred up by Menestheus, a descendant of Erechtheus, one of the old kings of Athens. Failing to quell the outbreak, Theseus in despair sent his children to Euboea, and after solemnly cursing the Athenians sailed away to the island of Scyros, where

EXPLOITS OF THESEUS; VASE PAINTING

Theseus (left) attacking the Crommyonian sow and (right) hoisting Sinis on his own pine tree

he had ancestral estates. But Lycomedes, king of Scyros, took him up to a high place, and killed him by casting him into the sea. His ghost was said to have appeared in the Athenian ranks at Marathon. When the Persian War was over, the Delphic oracle bade the Athenians fetch the bones of Theseus from Scyros and lay them in Attic earth. This was done, in 469, by Cimon.

Theseus' chief festival, called Theseia, was on the 8th of the month Pyanopsion (in October), but the 8th day of every month was sacred to him.

The well-preserved Doric temple to the north of the Acropolis at Athens, commonly known as the Theseum, is certainly not his shrine. There were several (according to Philochorus, four) temples or shrines of Theseus at Athens.

Farnell, *Hero Cults of the Greek States*. See also the two novels by Mary Renault, *The King Must Die* (1958) and *The Bull From the Sea* (1962).

**THESMOPHORIA**, a very ancient festival, in honour of Demeter Thesmophoros, celebrated by women in many parts of the Greek world (as Attica, many places in the Peloponnese, Boeotia, several islands, the coast of Asia Minor, Cyrene, Italy and Sicily, but not generally among the Dorians).

The name Demeter Thesmophoros does not mean, as the ancients usually supposed, *legifera Ceres* ("lawgiving Ceres," Ceres being equivalent to Demeter), since the festival has no aspects in any way connected with the bringing or establishing of laws or customs (*thesmoi*). It is possibly "bringer of treasure or wealth," an obsolete sense of *thesmos*, of which a few traces remain. Or, perhaps better, the name Thesmophoria is the primary one, from which the epithet of the goddess is derived, and it means "the carrying of things laid down," the radical meaning of *thesmos* referring to the fertility charms described below. As no men were admitted to the rites, and in any case they were largely secret, nothing like a full description is available.

The celebrants were women who seem to have been at least generally married, and who had to be free. They observed chastity for several days (nine, according to Ovid, a likely number considering its magical connotations), and abstained from certain foods; thus, they must not eat pomegranate seeds. The festival lasted three days, although in Attica it was lengthened by the addition of other celebrations of a similar character, the Stenia and the Halamusian Thesmophoria, making five days in all, Pyanopsion 10–14. But the original days were Pyanopsion 12–14 only (i.e., in what is now October) and shortly after the Pyanopsia (q.v.). The days were called respectively *Anodos* (or *Kathodos*), *Nesteia*, *Kalligeneia*.

*Anodos* (ascent) is often taken to mean the "going up" of the women to the Thesmophorion, or precinct of Demeter; but this does not explain why the day should also be called *Kathodos*, or descent. As the name of the second day, which signifies "fasting," describes what the celebrants then did, it is plausible to take the first day as having been called Ascent and Descent, and to connect it with the rite known to have been performed at some time in the festival. Pigs were thrown into an underground chamber, called a *megaron*; they were probably alive, but the text is corrupt and uncertain. At all events they were left there until such parts of them as were not eaten by the guardian snakes of these underground sanctuaries had had time to rot. The remains were then brought up by certain women who had observed chastity for three days and were called *antletriai* or "drawers up"—the verb *antlein* means to pump or draw off water. These women also carried, or some of the celebrants did, certain well-known symbols of fertility, including pine cones and "figures made of flour of wheat, in imitation of the shapes of serpents and of men." The remains of the pigs were laid on an altar, and if taken and mixed with seed were believed to ensure a good crop. Apparently the figures, like the pigs, were thrown into the chasms; but the authority here (a scholiast on Lucian) is both confused and manifestly corrupt; he seems to be confusing the Thesmophoria with a quite different festival, the Arrhephoria.

If, however, pigs, pine cones, figures and all were thrown into the *megara* and "pumped" out again, it is very intelligible magic.

These objects are all, in their nature, connected with fertility—a fertile beast, a seed vessel, a preparation of grain shaped like a creature supposed to be full of earth magic (the serpent) and like a man, perhaps a phallic figure. They are then put into a holy place, left there to acquire additional mana from the sacred surroundings and the touch of the sacred serpents, real or imaginary, who live there, and finally taken out again by pure agents, whose chastity has, so to speak, insulated them. Finally, they are laid on a holy altar, whence they are taken, heavily charged now with potency, and used to bring the blessing of fertility. To mix all manner of magical things with seeds to make them sprout better is a widespread primitive custom.

The ancients tried to explain all these matters as commemorations of the abduction of Kore; but it is rather the legends that grew out of the ritual, now no longer understood. In modern times it has been found possible to conjecture a reason for them; but it is to be remembered that, because of the fragmentary state of available knowledge, the above is offered as a conjecture only, especially as regards the date of the rite.

The *Nesteia* is easily enough explained; it is known that the women fasted, sitting upon the ground. Fasting is a common piece of agricultural magic, and contact with the ground is also common. The third day, *Kalligeneia*, is "the fair birth." We need not take it as originally referring to anyone so definite as Kore; it rather indicates the happy issue of all this magic, and doubtless of much more that is not known, in the fertility of the ground and doubtless of men and beasts as well. It remains only to add that the Thesmophoria, or at least a great part of it, was carried out at night by torchlight, and that it was accompanied by ceremonial coarse abuse among the women; again a common means of promoting fertility. The festival formed a setting for Aristophanes' comedy *The Thesmophoriazusae*. See also FEAST AND FESTIVAL.

**THESPIAE** (Greek THESPIAI), an ancient Greek city of Boeotia by the Thespius (modern Kanavari) River, on level ground commanded by the low eastward spurs of Mt. Helicon. Thespie, inhabited in Neolithic and Mycenaean times, was one of Boeotia's larger cities and figures chiefly as an enemy of nearby Thebes. During the Persian invasion of 480 B.C., almost alone among Boeotian cities, it joined the Greek resistance; 700 Thespians accompanied Leonidas to Thermopylae and of their own free will shared his death. Thespie was burned by Xerxes, but the remaining inhabitants furnished 1,800 unarmed men to the Greek army at Plataea (479). In 424 the Thespian contingent at Delium sustained heavy losses, and next year the Thebans took advantage of this to accuse Thespie of friendship toward Athens and to dismantle its walls. In 414 the Thebans interfered again to suppress a democratic rising. In the Corinthian War Thespie sided with Sparta, and between 379 and 372 it repeatedly served the Spartans as a base against Thebes. The Thespians were reduced by the Thebans and compelled to send a contingent to Leuctra (371); after this Theban victory the entire population evacuated Thespie, which the Thebans destroyed. The town was soon rebuilt. In 171, true to its policy of opposing Thebes, Thespie supported the Romans, who declared it a free city in 146 B.C.

The deity most worshiped at Thespie was (unusually) Eros, whose primitive image was an unwrought stone. The town contained many works of art, among them the marble Eros of Praxiteles, dedicated by the famous courtesan, Phryne, who was born at Thespie, and one of the most famous statues in the ancient world; it was carried off to Rome by Caligula, restored by Claudius, and removed again by Nero. There was also a bronze Eros by Lysippus. The Thespians also worshiped the Muses and celebrated a drama and poetry festival in their honour in the sacred grove on Mt. Helicon. There are remains of the sanctuaries of the Muses both at Thespie and on Mt. Helicon. See also BOEOTIA.

**THESPI** (6th century B.C.), Greek poet from the Attic country-deme of Icaria. He was often reckoned the "inventor of tragedy" and the Parian Chronicle (*q.v.*) records his name as the first to win a prize for tragedy at the City Dionysia, c. 534 B.C. The significance of the claim depends on the interpretation of scanty and summary evidence about Thespis, and the view taken of the origins and development of Greek drama. Aristotle, according to the rhetorician Themistius, said that in its earliest stage tragedy was entirely choral, the prologue and speeches being first introduced by Thespis. If this be accepted—and on linguistic grounds it is perfectly possible—then the contribution of Thespis was indeed decisive: he was the first "actor," and tragic dialogue began when he exchanged words with the leader of the chorus. The Suda Lexicon gives the titles (of doubtful authenticity) of several of his plays (not confined to the legends of Dionysus, but embracing the whole body of heroic legends), but the fragments quoted in various writers as from Thespis (*see* A. Nauck, *Fragmenta Tragicorum Graecorum*, 2nd ed., 1926) are probably forgeries by Heracleides Ponticus. The statement of Horace in the *Ars poetica* that Thespis went round Attica with a cart, on which his plays were acted, seems to be due to a confusion between the origins of tragedy and of comedy. (A. M. DE.)

**THESSALONIANS, EPISTLES TO THE**, two books of the New Testament, the items placed last in the traditional collection of the Pauline Epistles that are addressed to a congregation. According to the usual dating they are the earliest extant letters of Paul and hence the earliest of surviving Christian documents (though this hinges on the date of Galatians, which is disputed; *see* PAUL, SAINT: *Letters and Style*). They are closely connected to one another not only in that they are both addressed to the same congregation at Thessalonica (modern Salonika, in Macedonian Greece) but also by similarity of wording and content, including the fact that Silvanus (Silas) and Timothy are mentioned in the opening sentence of both epistles as being co-authors with Paul. These very resemblances have given rise to the literary problem of the second letter, whose authenticity is much debated and cannot be proved with certainty, though there is no reasonable doubt among modern scholars that the first letter is the work of Paul.

**Contents.**—The two books may be outlined as follows:

I. Thess.	1:1	greeting
	1:2–10	thanks to God for the Thessalonians' faith and good conduct
	2:1–12	Paul's defense of his own motives and conduct when staying with them
	2:13–3:13	Timothy's good report, and a prayer for the Thessalonians
	4:1–12	warnings and exhortations
II. Thess.	4:13–5:11	the dead and the living at the Second Coming, which will be soon
	5:12–28	exhortations and conclusion
	1:1–2	greeting
	1:3–12	thanks to God for the Thessalonians' faith and good conduct and reference to God's retribution on their enemies
	2:1–12	warning against false reports of the end of the world
	2:13–3:5	renewed thanks
	3:6–16	warnings and exhortations
	3:17–18	conclusion

**I Thessalonians.**—*Themes.*—After the introductory greeting (1:1) Paul gives thanks for the faith and love of the congregation, which are an example to all (1:2–10). He then looks back at his own stay in Thessalonica, defending himself against the accusation that his missionary work there had selfish motives by pointing out that he earned his own living in their city concurrently with preaching the gospel (2:1–12). After renewed thanks for the Thessalonians' progress in the Word of God, Paul tells them how much he had longed to visit them again, but because he could not do so he had sent Timothy. Timothy has just returned with news of them which leads Paul to pray that they may continue blameless (2:13–3:13). An exhortation against sexual immorality and dishonesty follows, together with an exhortation to brotherly love and working peaceably for their living (4:1–12). Paul then turns to a special problem: there was some concern in the

congregation about those who had died before the Second Coming, and Paul assures them that those Christians who have died already will rise to meet their Lord first, before we who are still alive are also caught up into the clouds with him (4:13–18). The day of the Lord will come unexpectedly, and the Thessalonians must be prepared for it (5:1–11). After some general exhortations (5:12–25) the letter ends with the unexpected command to read the letter to all the brethren and with the usual formula of benediction (5:26–28).

The epistle was clearly written just after Paul had received news of the Thessalonians from Timothy and wanted to express his joy over them. As he cannot immediately visit them himself (3:10), he wants to strengthen their faith by writing (4:1 ff.), and in this part of the letter, quite possibly, he may be also answering questions the congregation sent to him. In any case he has heard of the uncertainties caused by the death of some Christians, and one gets the impression that he is also aware of a certain tension between "those who labor among you and are over you in the Lord and admonish you" (5:12) and the rest of the brethren (5:12–14, 27). It need not, however, be assumed that every exhortation or self-justification in the letter must necessarily refer to some feature of the situation in Thessalonica.

*Place and Date of Writing.*—Though the motives for writing the letter are clear enough, it is not so easy to place it in its historical setting. Paul was anxious for news of the Thessalonians, whom he had visited only once (2:17), and he had apparently left Athens just at the time when he sent his friend Timothy to Thessalonica. This situation fits quite well with the events narrated in Acts 17:1–18:5: Paul had to flee from Thessalonica to Beroea and from there to Athens, after which he reached Corinth without his companions Silas and Timothy, who joined him soon after. Most scholars therefore think that the First Epistle to the Thessalonians was written in Corinth at some time after Paul's arrival there from Athens.

The objections to this view are that there was hardly time, so soon after Paul left Thessalonica, for several Christians to have died and for news of the Thessalonians' faith to have spread beyond Greece (4:13 and 1:8). The scholars who make these objections suggest that, as the polemic in 2:1 ff. is similar to that in the Epistles to the Corinthians, the First Epistle to the Thessalonians was probably written four years later, when Paul during his stay in Ephesus was in controversy with the Corinthians about the same problems. There is no *a priori* reason, however, against several deaths occurring in Thessalonica during a short space of time, and the reference to Paul's having for the first time received news from Thessalonica (3:6) cannot be reconciled with the theory that the epistle was written four years later. It is therefore more likely that the view of the majority of scholars is right: that I Thessalonians was written in Corinth, shortly after Paul first arrived there. According to the usual chronology, the date of the epistle would be A.D. 50 or 51.

**II Thessalonians.**—*Themes.*—After an introductory sentence (1:1–2) that is almost identical with that of I Thessalonians, Paul begins with thanksgivings that pass over into a description of God's retribution on their enemies (1:3–12). He then warns them not to be agitated by the rumour that he had said or written anything which implied that "the day of the Lord has come." He reminds them how he told them that before the Second Coming the "man of lawlessness" (*i.e.*, Antichrist) must appear and that this "son of perdition" is hindered from coming by "him who now restrains him" (2:1–12). But Christians know that they are called to salvation, and Paul is sure that God will guard the Thessalonians from evil (2:13–3:5). The epistle ends, like I Thessalonians, with various admonitions, including the necessity of work, and of shunning those who disobey Paul's commands on this point (3:6–16). The concluding benediction emphasizes that Paul's own hand wrote these last lines (3:17–18).

*Question of Authenticity.*—If I Thessalonians were no longer extant, no one would doubt the authenticity of II Thessalonians. Comparison of these two epistles, however, reveals far more similarity of content and wording than one would expect in two letters addressed in fairly quick succession to the same readers, and on the

other hand a marked difference between them in eschatological teaching. In I Thessalonians Paul says that the day of the Lord will come quickly, yet in II Thessalonians he reminds them that Antichrist and his "restrainer" must come before the Lord can appear. The expectation of the eschatological events in I Thessalonians seems less complicated than that in II Thessalonians, so some scholars hold that II Thessalonians is spurious while others avoid some of the problems by supposing that the second letter was in fact written first or that it was originally addressed to another congregation or to a special group within the Thessalonian congregation.

The difficulties, however, are really not so great as they seem at first sight. The difference in eschatological ideas can be explained on the supposition that during the period that elapsed between the sending of the two letters an unsound eschatological excitement had developed in the congregation. One should also remember that Paul is merely reminding the Thessalonians of a doctrine—complementary to the ideas developed in I Thess. 4: 13 ff.—which he taught when he was among them. If Paul wrote the second letter soon after the first one, it would be natural for them to be similar in content. It is therefore probable that II Thessalonians was the work of Paul, but as it gives no indication of date one is reduced to guesswork in suggesting that it may have been written not long after I Thessalonians and may also have originated in Corinth.

**Significance.**—The importance of these two epistles is twofold. They embody the theology of Paul in its earliest form and they indicate the difficulties created by the Christian message in pagan surroundings. Further, they help toward a fuller understanding of Paul's eschatological ideas and his adaptation of Jewish apocalyptic to Christian theology. See also BIBLE.

**THESSALY (THESSALIA)**, a district of northern Greece, lies south of Macedonia, and between upland Epirus and the Aegean Sea. It forms an irregular square, about 60 mi. (about 100 km.) in each direction, and is encircled by natural boundaries: the Cambunian (Kamvounia) Mountains on the north, Othrys (Othris) on the south, and the chain of Pindus (Pindhos) on the west; at the northeastern angle is Olympus, separated by the gorge of Tempe from the coast range of Ossa and Pelion, which forms a continuous line to the southeast. It is drained by the numerous confluent of the Peneus (Pinios) River, which flows into the sea through Tempe, and is essentially an agricultural and pastoral district, its plains producing wheat, maize (corn), rice, cotton, and tobacco. It is divided into the *nomoi* of Kardhitsa, Larisa, Magnisia, and Trikkala. Area 5,395 sq.mi. (13,973 sq.km.); pop. (1961) 695,385.

Through Thessaly lie all land routes between peninsular Greece and the north. Xerxes entered it by the Petra Pass, which comes down west of Olympus into the plain north of Larissa. The route taken from Epirus by Julius Caesar before the Battle of Pharsalus (48 B.C.) passed over Mt. Lacmon to Aeginium (modern Kalabaka), in the northwestern angle, whence there is now a road via Metsovo to Ioannina. Another pass, farther south near Gomphi (mod. Gomfoi), leads through the "Gates of Trikkala" to Arta and the Ambracian Gulf. The great southern pass of Coela, followed by the modern highway, crosses Mt. Othrys nearly due north of Thermopylae. The main railway line from Athens to Salonika enters Thessaly by this pass, reaches Larissa, and makes its way through the gorge of Tempe and along the sea front of Olympus. Larissa is connected by rail with the port of Volos; and another

line runs from Volos westward to Kardhitsa, Trikkala, and Kalabaka.

Though Thessaly is the most level district of Greece, it is divided by ranges of hills into two sections: that to the west and southwest, which is dominated by the town of Trikkala (*q.v.*), and that to the east, which centres on Larissa (*q.v.*). The ancient political divisions or "tetrads" followed the physical, Pelasgiotis being the lower plain of the Peneus, Histiaeotis and Thessaliotis respectively the north and south portions of the upper; the fourth, Phthiotis, the realm in legend of Achilles, lay to the southeast. The Gulf of Volos (*q.v.*) on the east is enclosed by the Magnesia peninsula, an extension of the chain of Pelion. The Argonauts (*q.v.*) set sail from this landlocked bay.

**History.**—The history of Thessaly is closely connected with its geography. The fertility of the land offered a temptation to invaders from the earliest times. It was the home of an extensive Neolithic culture deriving probably from Asia Minor or Syria, which was interrupted about 2500 B.C. by immigrants from the north who constructed fortified settlements, such as that at Dhimini near Volos. Thessaly remained at first rather on the fringe of the great Bronze Age civilization of Greece, although Mycenaean settlements have been discovered, e.g., at Iolcus near Volos. Toward the end of the Mycenaean period, however, it was overrun by a new wave of invaders. The tribe of the Thessali, coming from Thesprotia in southern Epirus, entered the plain of Thessaliotis and imposed an aristocratic rule on the older inhabitants, who became their vassals or took to the surrounding hills. The rich lowlands were the natural home of baronial families such as the Aleuadae of Larissa and the Scopadae of Crannon, who organized a pan-Thessalian federation under an elected military chief (*tagos*), and controlled the Amphictyonic League of northern Greek states in the 6th century B.C. The plains were also suited to horse breeding, and consequently the Thessalians were strong in cavalry. But the isolation and the semi-Hellenic character of the people held them aloof from the main currents of Greek history in the classical period. At the time of the Persian Wars the Aleuadae joined the Persians; and the rivalries of the leading families promoted political instability. United, as under Jason of Pherae in the 4th century, the Thessalians were formidable, but they seldom combined for long and had little influence in Greece. After the 4th century they were usually Macedonian vassals, until liberated by the Romans and incorporated in the Roman province of Macedonia in 148 B.C.

Diocletian made Thessaly a separate province c. A.D. 300 with its capital at Larissa; and in the Byzantine Empire it was attached to the theme of Thessalonica. In the 7th century it was invaded by Slavs, and in the 9th its coasts were frequently raided by Arab pirates, who destroyed the port of Demetrias in 902. The Bulgars, who had attacked it in the 8th century, conquered it in the 10th. Byzantine rule was restored by Basil II, and was maintained by his successors (except for a brief Norman occupation at the end of the 11th century) until the Fourth Crusade (1204), when Thessaly was taken over, with Thessalonica, by Boniface of Montferrat. It was soon recovered by the Greek ruler of Epirus, Theodore Angelus, whose descendants held it until 1318 as an independent principality, with its capital in the south at Neopatra (Ipati), and maintained close ties with the French dukes of Athens and Thebes and with the Angevin claimants to the Morea. The settlement of nomad Wallachians or Vlachs from the Danube area had become so extensive by the 12th and 13th centuries that Thessaly came to be called Great Wallachia (*Megale Vlachia*); and there are still colonies of Vlach herdsmen in the surrounding hills, who come down into the Thessalian plains during the winter. In 1309 Thessaly was temporarily overrun by the Almogávares (*q.v.*); and in 1333 it reverted to the status of a Byzantine province, though dominated, as it had been in ancient times, by a few aristocratic families, such as the Melissenis and the Gabrielopoulis, who had learned feudal manners from their French neighbours. In 1348 it was occupied by the armies of the Serbian Stephen Dushan, whose half-brother, Symeon Urosh, set up his capital at Trikkala. For a short period after 1381 it was again Greek, until its total conquest by the Turks in 1393, when Trikkala became the seat of the

pasha of Thessaly. Most of the country was ceded to Greece by the Turks in 1881, the frontier being drawn a little to the north of Tempe; after the Balkan Wars of 1912-13 all of Thessaly passed into the kingdom of Greece. The area was fought over in the Greco-Turkish War of 1897, and again in World War II.

**THETFORD**, a municipal borough in the South Norfolk parliamentary division of Norfolk, Eng., 29½ mi. (47.5 km.) WSW of Norwich by road. It is the centre for the Breckland and is on the edge of Thetford Chase Forest. Pop. (1961) 5,399. In the time of Edward III there were 20 churches and 8 religious houses, but now there are only 3 parish churches and the remains of a Cluniac priory (excavated by the Ministry of Works) and a Benedictine nunnery. Castle Hill, a large medieval motte, is 80 ft. high. Excavations have revealed traces of a Saxon town of about 4,000 inhabitants with considerable industry and a mint. The grammar school has a record of headmasters from 1114, and may be mentioned in the Anglo-Saxon Chronicle as existing in 631. It was re-founded in 1567 by Sir Richard Fulmerstone. King's House, used by Elizabeth I and James I and reputed to stand on the site of the palace of William the Conqueror's son-in-law, was bequeathed to the corporation in 1946, and serves as municipal offices. There have been mayors since 1272, and the town is now governed under a charter of 1573. The borough regalia is fine and interesting. Thomas Paine, the reformer, was born there in 1737 and attended the grammar school. Industries include paper-pulp manufacturing, canning, coffee milling, and light engineering.

See T. Martin, *The History of the Town of Thetford* (London, 1779); A. L. Hunt, *The Capital of the Ancient Kingdom of East Anglia* (London, 1870).

**THETFORD MINES**, a city of Quebec, Can., 55 mi. (89 km.) S of Quebec City, famous for asbestos deposits discovered there in 1876; they produce more than half of the world's asbestos supply. The community, first known as Kingsville after one of the owners of the first mine, was later renamed for Thetford, Eng. It became a village in 1892, a town in 1905, and a city in 1912. Pop. (1961) 21,618.

On a picturesque slope, Thetford Mines soon found that the profitable mining operations had some unpleasant aspects: clouds of dust from the open-pit mining saturated the city; dreaded respiratory ailments occurred among the miners; and mountains of slag hemmed the city in on three sides. The asbestosis and silicosis were almost eliminated, and in the 1950s an entire housing district was moved and slag heaps were torn down in an effort to prevent the strangling of the city. (J. P. Le.)

**THIAZINES** are organic compounds, of which some of the more complex derivatives are of importance in the manufacture of dyestuffs. They have the molecular formula  $C_4H_6NS$ , to which six-membered heterocyclic ring structures have been assigned.

1,3,2-Thiazine

1,3,4-Thiazine

1,4-Thiazine

The thiazines themselves and their simpler derivatives are of little practical importance or theoretical interest. The so-called thiazine dyes are phenazothionium salts and may, therefore, be regarded as derivatives of phenothiazine (2,3,5,6-dibenzo-1,4-thiazine).

The simplest of the thiazine dyes is Lauth's violet (I); probably the most important is methylene blue (II).

The skeletal structure of the thiazine dyes was elucidated by August Bernthsen in 1887, although methylene blue was discovered in 1876 by Heinrich Caro. (P. H. O. R.; X.)

**THIAZOLES** are a class of organic compounds, some of which are notably versatile in synthetic reactions; in their own right they are important as cotton dyes. Thiazoles contain a five-membered ring of one nitrogen, one sulfur and three carbon atoms which are connected by three single and two double bonds in the following order:

The earliest synthesis of a compound of this type was effected in 1874, by the action of hydrogen sulfide on potassium cyanide; however, the constitution of this product remained long in doubt and was rigorously established, as 5-amino-2-thiocarbamylthiazole, only in 1947.

Thiazoles, as a class, were discovered in 1887 by Arthur Hantzsch, who then systematically explored their chemical characteristics. They are most conveniently prepared by the condensation of  $\alpha$ -halogenated aldehydes or ketones with thioamides:

The parent thiazole, in which  $\text{R}^1$ ,  $\text{R}^2$  and  $\text{R}^3$  represent hydrogen atoms, is a colourless liquid that boils at 117° C. and exhibits weakly basic properties like those of pyridine; the homologous thiazoles display similar properties.

The 2-aminothiazoles, in which  $\text{R}^3$  represents the amino group, are formed in an analogous reaction from thiourea; the sulfanilyl derivative, in which  $\text{R}^1 = \text{R}^2 = \text{H}$  and  $\text{R}^3 = \text{NH} \cdot \text{SO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{NH}_2$ , is the synthetic antibiotic drug sulfathiazole.

The 2-hydroxythiazoles, in which  $\text{R}^3 = \text{OH}$ , are produced by the action of alkali upon  $\alpha$ -thiocyanoketones:

The corresponding 2-mercaptothiazoles ( $\text{R}^3 = \text{SH}$ ), formed by the interaction of  $\alpha$ -halogenated ketones with ammonium dithiocarbamate, find industrial use as accelerators in the vulcanization of rubber.

The 5-aminothiazoles ( $\text{R}^1 = \text{NH}_2$ ) have been prepared by treating  $\alpha$ -amino nitriles with carbon disulfide and then removing the sulphydryl group (at position 2) from the product by the action of Raney nickel catalyst:

Dihydrothiazoles, or thiazolines, have been prepared by the action of ethylene dibromide upon thioamides:

or, less conveniently, from acid chlorides or anhydrides and  $\beta$ -amino thiols.

Tetrahydrothiazoles, or thiazolidines, are formed by the interaction of aldehydes or ketones with  $\beta$ -amino thiols:

In 1935 and the subsequent two decades the thiazole group and its hydro analogues were shown to occur in natural products: thiamine (vitamin B<sub>1</sub>) contains a thiazole nucleus, the penicillins are derivatives of thiazolidine and there are indications that the thiazole ring may be present in the antibiotic bacitracin.

See Sir Ian Heilbron, *J. Chem. Soc.* 2099 (1949); Roger Adams et al. (eds.), *Organic Reactions*, vol. 6, ch. 8 (1949–51). (H. T. C.)

**THIBAUT IV** (1201–1253), count of Champagne and Brie, and king (as Tibald I) of Navarre from 1234, was the most famous of the aristocratic *trouvères* (q.v.), thrice cited by Dante in his *De vulgari eloquentia*. He was born at Troyes in 1201, probably on May 30, the posthumous son of Thibaut III and Blanche of Navarre, and lived for four years at the court of Philip II (Philip Augustus), to whom he did homage in 1214. He deserted Philip's son Louis VIII at the siege of Avignon in the late summer of 1226. On Louis' death a few months later, he joined the dissident baronial league which opposed the new queen mother, Blanche of Castile, but soon abandoned it and became reconciled with Blanche. It was rumoured that he was her lover and had poisoned her husband, and many of his poems are thought to be addressed to her. As leader of the Crusade of 1239 he won back Beaufort, Safed (Safad), and Ascalon for the Christians. After his return he spent the rest of his life in Champagne and in his kingdom of Navarre, where he died at Pamplona in 1253, probably on July 7.

Thibaut left about 60 lyrics, mainly lovesongs and debates in verse, with two *pastourelles* (lovesongs between knight and shepherdess), and nine religious poems. His verse now seems conventional; only occasionally, as in the heptasyllabics of no. 17 in Wallensköld's edition ("The hind is up and away/And she is white as the snow/And both the braids of her hair/Are brighter than Spanish gold"), does it convey a genuine mood of urgency. Perhaps he finds his true level in the *jeu-parti* (courtly love-debate) in which he discusses with a crusading crony, Raoul de Soissons, whether it is better to embrace one's love in the dark or to see her without embracing her, with wry allusions to Thibaut's potbelly and Raoul's crutch (no. 43). Thibaut's reputation is due to the fortunate survival of his lyrics, with their music, in six manuscripts (*K, M, O, T, V, and X*), of which three have been published in facsimile (see *Bibliography*).

**BIBLIOGRAPHY.**—The standard edition of Thibaut's *chansons* is *Les Chansons de Thibaut de Champagne, roi de Navarre*, ed. by A. Wallensköld, for the Société des anciens textes français (1925). Earlier editions were published by L. A. Levesque de La Ravalière (1742), and P. Tarbé (1851). The facsimiles appear in *Le Chansonnier de l'Arsenal* (ms. *K*), ed. by P. Aubry and A. Jeanroy (1908 ff.); *Le Manuscrit du Roi* (ms. *M*), ed. by J. B. and L. Beck (1938); and *Le Chansonnier Cangé* (ms. *O*), ed. by J. B. Beck in *Les Chansonniers des troubadours et des trouvères* (1927). See also M. Roques, "Le Chansonnier français de Zagreb," in *Mélanges . . . offerts à M. Alfred Jeanroy* (1928); S. Runciman, *A History of the Crusades*, vol. iii, pp. 212–217 (1954); F. Gennrich, *Altfranzösische Lieder*, 2 vol. (1955–56), *Exempla altfranzösischer Lyrik: 40 altfranzösische Lieder* (1958); His Master's Voice Records, *The History of Music in Sound*, vol. ii, side 2 (1957). (C. A. RN.)

**THIBAUT, ANTON FRIEDRICH JUSTUS** (1772–1840), German jurist and leader of the philosophical school which maintained the tradition of natural law in a spirit of moderate rationalism. He is remembered chiefly because his demand for the codification of German law provoked F. K. von Savigny's famous retort "On the Calling of Our Time for Legislation," in which the leading ideas of the historical school of law were formulated. Thibaut was born at Hameln, Ger., on Jan. 4, 1772. He studied law at Göttingen, Königsberg, and Kiel, where, in 1796, he qualified as teacher of law. He was appointed professor of civil law at Kiel in 1798, then at Jena in 1802, and at Heidelberg in 1806. In 1834 he became a member of the court of arbitration of the German Confederation. He died in Heidelberg on March 28, 1840.

His principal publications are *Theorie der logischen Auslegung des römischen Rechts* ("Theory of the Logical Interpretation of Roman Law," 1799) and *System des Pandektenrechts* (1803; the general part translated as *An Introduction to the Study of Jurisprudence*, 1879), which remained for some time one of the leading textbooks of Roman law applied as the common law of Germany. In 1814 he published an essay "On the Need for a Civil Code for Germany," which was inspired by patriotic sentiment and by rationalist belief in the merits of codification. Thibaut was also a serious student of music and wrote *Über Reinheit der Tonkunst* (1825; trans. *On Purity in Musical Art*, 1877).

**THIERRY OF CHARTRES** (d. c. 1150), in Latin called THEODORICUS or TERRICUS CARNOTENSIS, French encyclopaedist, philosopher, and theologian, was a brother of Bernard of Chartres. He taught in Paris and at Chartres, where he became chancellor in 1141, having among his pupils John of Salisbury and possibly Abelard. His unpublished *Heptateuchon* (preserved in microfilms at Oxford, at Toronto, at Chartres, etc.) contains the "classics" of the seven liberal arts (works by Aelius Donatus and Priscian for grammar, by Cicero and Martianus Capella for rhetoric, by Aristotle and Porphyry for logic, etc.). His cosmology, mainly expounded in his commentary on *Genesis*, makes an attempt to harmonize Scripture with Platonic and other physical or metaphysical doctrines. He was among the first to promote in the Latin west the knowledge of science as professed by the Arabians.

(L. M.-Po.)

**THIERRY, (JACQUES NICOLAS) AUSTOIN** (1795–1856), French historian whose discursive method of presenting history in picturesque and dramatic terms makes him one of the outstanding Romantic historians. Born at Blois on May 10, 1795, he was educated there and at the École Normale in Paris, where he first met Saint-Simon (q.v.). He was fired with Saint-Simon's ideal society of the future, becoming his secretary in 1814 and always calling himself the "adopted son" of the visionary. But, while most of Saint-Simon's followers turned their attention to practical matters, Thierry turned to history.

As a professional historian he was influenced particularly by the works of Sir Walter Scott, and, though he himself wrote no romances, his conception of history fully recognized the dramatic element. He was also greatly impressed by *Les Martyrs* (1809), the prose epic in which Chateaubriand contrasts the two civilizations (pagan and Christian) and two peoples (Greek and Roman) from which the modern world has sprung. His main subjects are the Germanic invasions, the Norman Conquest, the formation of the medieval communes, the gradual ascent of the nations toward free government, and parliamentary institutions.

His first articles, which appeared in *Le Censeur européen* and *Le Courrier français* (1817 et seq.), he published under the title of *Dix Ans d'études historiques* (1834). From Claude Fauriel (q.v.) he learned to consult original sources; and in writing his most original and ambitious work, *L'Histoire de la conquête de l'Angleterre par les Normands* (three volumes, 1825; English translation, 1825), he made use of Latin chronicles and Anglo-Saxon laws. This work cost Thierry his eyesight. He was obliged to engage secretaries, and in 1830 he became totally blind. In 1827 he republished his *Lettres sur l'histoire de France* (first published, 1820), with the addition of 15 new letters, in which he describes some of the more striking episodes in the history of the rise of the communes. His *Récits des Temps mérovingiens*, in which he reproduces in a vivid form some of the most characteristic stories of Saint Gregory of Tours, appeared between 1835 and 1837 in the *Revue des deux Mondes*; when collected in two volumes in 1840, they were preceded by several interesting *Considérations sur l'Histoire de France*. In 1841 the French Academy awarded him the first Prix Gobert, a prize bestowed on him for the next 15 years.

An ardent supporter of the revolution of July 1830 and of the triumph of liberal ideas, Thierry was always interested in the des-

tiny of the third estate, as is evident from the large *Recueil des monuments inédits de l'histoire du Tiers État* (four volumes, 1850-70), which he compiled with the help of zealous collaborators. He died in Paris on May 22, 1856.

See A. Augustin-Thierry, *Augustin Thierry* (1922); K. J. Carroll, *Some Aspects of the Historical Thought of Augustin Thierry* (1951).

**THIERS, LOUIS ADOLPHE** (1797-1877), French statesman, journalist, and historian, an outstanding figure in French politics from 1830 to 1877, was twice premier under Louis Philippe and head of the executive from 1871 to 1873 during the Third Republic. He was born at Marseilles on April 18, 1797. His father married his mother on May 13 and deserted her four months later. Thiers was educated by the financial help of friends and relatives and won a scholarship to the *lycée* of Marseilles, which now bears his name. He was later a student at the law faculty at Aix-en-Provence, where he met his lifelong friend, the historian François Mignet. After he was called to the bar in 1818, his very small practice gave him ample opportunities to pursue historical studies. In September 1821 he went to Paris, where the Liberal deputy of Basses-Alpes, Jacques Manuel, introduced him to the world of journalism, and Thiers became a regular contributor to the *Constitutionnel*, the most influential newspaper of that period. At the same time he was a correspondent for the *Allgemeine Zeitung*, published by Freiherr Cotta von Cottendorf, and he also

began to collect documents for his *Histoire de la révolution française*, which appeared in 10 volumes between 1823 and 1827. In 1822, just prior to the French intervention in Spain to suppress the revolutionary government there, he traveled in southern France and on the Pyrenean border. He was almost the only Liberal to predict the success of the absolutists in Spain, and thus enhanced his reputation.

**The July Monarchy.**—In January 1830, together with Armand Carrel and Mignet, and probably with Talleyrand's support, he founded a new opposition newspaper, the *National*, which almost openly advocated a change of dynasty to forestall any attempts of Charles X to circumscribe public liberties. Thiers

ARCHIVES PHOTOGRAPHIQUES, PARIS

THIERS, DETAIL FROM A PORTRAIT BY LÉON BONNAT, 1876; IN THE LOUVRE

was the first signatory of the journalists' protest which immediately followed the publication of the ordinances of July 26, 1830, by which Charles aimed to control the Chamber. During the revolution of July 27-29 which overthrew Charles, he took refuge in a southern suburb of Paris and returned on the 29th to win support for Louis Philippe, duc d'Orléans. He was rewarded by being made a member of the council of state, was elected to the Chamber as a deputy for Aix (a seat he held until 1848), and in November 1830 became undersecretary of state for the treasury.

He was successively minister of the interior (1832), minister of trade and public works (1833-34), and of the interior again (1834-36), and during these years he was the most notable representative of the Party of Resistance (moderates). He efficiently and mercilessly crushed all insurrections against Louis Philippe's regime, in particular those of the Legitimists under the duchesse de Berry in 1832 and of the Republicans in 1834. Premier and minister of foreign affairs (February-August 1836, and March-October 1840), in his second term of office his adventurous foreign policy in support of Mohammed Ali during the Egyptian crisis (see *EASTERN QUESTION*) almost led to war with Great Britain. Forced to resign by Louis Philippe's determination not to go to war, Thiers still remained one of the leaders of the Resistance, but he weakened its cause by his personal opposition to François Guizot (q.v.). He now traveled in Europe, gathering material for his *Histoire de consulat et de l'empire*, which was

published in 20 volumes between 1845 and 1862. He consulted the most important living witnesses of the period, though these were not always satisfied with the interpretation he placed upon their evidence. Meanwhile, with his father-in-law Alexis Dosne, a stockbroker and businessman, Thiers made many profitable speculations as a result of information he received through his close relations with these in power. He thus became one of the great property owners in Paris.

**The Second Republic.**—On the morning of Feb. 24, 1848, in the midst of the Revolution, Louis Philippe called on Thiers to form another ministry; but by then it was too late and the king abdicated that same afternoon. During the Second Republic (1848-52), Thiers was defeated (April 1848) in his old seat for Aix in the *département* of Bouches-du-Rhône by the influence of the young commissary-general Emile Ollivier, whom he was later to attack with much bitterness in parliament at the end of the Second Empire. However, in June Thiers was elected to the Constituent Assembly for several other *départements*, choosing to sit for Seine Inférieure, and immediately became one of the most influential leaders of the Conservatives, the champions of order. As such he was responsible for the choice of Prince Louis Napoleon (afterward Napoleon III) as a candidate for the presidency of the Republic (December 1848). In both the Constituent and Legislative Assemblies Thiers voted for the reactionary laws which weakened the Republic and which contributed to the growing differences between himself and the president. When Louis Napoleon carried out his *coup d'état* of Dec. 2, 1851, Thiers was arrested and exiled. He was allowed to return to France in 1853.

**The Second Empire.**—For ten years Thiers lived a retired life, supporting the Orléanist opposition and also plotting principally with those Catholic elements who were alarmed by Napoleon III's foreign policy in Italy (see *ITALY: History*). In 1863 he was elected deputy for the Seine and thereafter took an important part in the parliamentary debates, attacking the government's financial and political policies. He was particularly vehement in denouncing anything detrimental to French prestige, and did much to arouse in his countrymen a nationalistic and militarist frame of mind. This attitude finally forced Ollivier's ministry into its quarrel with Prussia in July 1870 over the candidature of Prince Leopold of Hohenzollern-Sigmaringen to the Spanish throne (see *Franco-German War*), although much needed army reforms in France had not been carried out. During the crisis, however, Thiers changed his views and became an opponent of the aggressive policy he had previously advocated. This reversal stood him in good stead after the French defeat (September 1870), for his friends were able to present him as one who had regretted the French diplomatic ineptitude and had known that French military preparations were inadequate.

**President of the Third Republic.**—Instead of taking his place on the government of national defense, set up in Paris on Sept. 4 after Napoleon's surrender at Sedan, Thiers traveled throughout Europe in search of a mediator, but found that no government was prepared to offer help to the representative of a purely provisional government. He thus had no responsibility for the organization of defense, nor for the final French surrender in January 1871. In February 1871 he was elected simultaneously to 26 *départements* and on Feb. 17 became "chief of the executive power of the French Republic." Together with Jules Favre he then negotiated with Otto von Bismarck the peace treaty that was finally signed at Frankfurt on May 10. Thiers's well-known sayings "The Republic will be Conservative or will fail" and "The Republic is the system of government that divides us the least" are perhaps the best definitions of his political beliefs at this time, for he was confronted by three "monarchist" parties, the Legitimists, Orléanists, and Bonapartists, who were all anxious to prevent each other's success.

One of Thiers's first tasks was to preserve the social order. On the outbreak of the Paris insurrection known as the Commune of Paris (q.v.) on March 18, 1871, Thiers put into operation a plan he had prepared at the time of the 1848 Revolution, withdrawing all regular troops from the city. He then negotiated with Bismarck for the return of the Imperial regiments captured in

eastern France. With these troops he laid siege to Paris on the western and southern sides of the town, while the Germans kept watch on the other fortifications. The fall of the Commune during "La semaine sanglante" (the bloody week) of May 21-28, 1871, destroyed for many years the strength of the socialists and of the workers' movements, both in Paris and in France as a whole. But even this success failed to win for Thiers the approbation of the Legitimists, who could never forget his responsibility for the arrest of the duchesse de Berry in 1832. Their hostility was further increased by Thiers's personal popularity, sedulously fostered by efficient propaganda.

In these circumstances Thiers was compelled to seek support in the National Assembly from the deputies of the Left and he succeeded by presenting himself as the symbol of the Republic against monarchists of all kinds. In August 1871 he was given the title "president of the French Republic." He had to rearrange his cabinet practically every year, and eventually fell back on older politicians of the July Monarchy, such as Charles, comte de Rémusat, and prominent businessmen, such as the financier Augustin Pouyer-Quertier.

Thiers was able to give ample proof of his ability in his skillful management of the relations between the "president of the executive" and the Assembly. He was also responsible for the military law of 1872 which overhauled the military system but failed to modernize the army. No provision was made for the organization of the reserves and the introduction of a period of service for five years (not revised until 1889), by withdrawing manpower, weakened the French economy at a time when the industrial development of other countries was increasing rapidly. In March 1873 he signed an agreement with Germany for the recall of its troops, the French indemnity having, by Thiers's good financial management, been paid off two years earlier than Bismarck had envisaged, but on May 24, 1873, he was defeated in the Assembly by the forces of the Right and resigned.

Thiers immediately took an important part in the republican opposition in the mainly royalist Assembly. He was one of the 363 deputies who passed a vote of no confidence in the duc de Broglie's ministry in June 1877 and he managed to reconcile the different republican groups for the coming election. Thiers died suddenly at Saint-Germain-en-Laye (Seine-et-Oise) on Sept. 3, 1877, while preparing an election manifesto.

Thiers probably achieved greater power and wealth than any French politician of his time, but his ability was not greatly appreciated even by those, such as Louis Philippe, whom he served. As a journalist he had a definite, though limited influence; as a historian his works were praised or condemned according to the political views of his critics, but nevertheless they made a notable contribution to the Napoleonic legend and to the growth of nationalism in France. Of himself, Thiers successfully promoted the image of an old, shrewd, and wise patriot, which was accepted by moderate republicans during the first 20 years of the Third Republic.

Besides his historical writings, Thiers's works included *Les Pyrénées et le Midi de la France . . . 1822* (1823); *Law et son système de finances* (1826), and *La monarchie de 1830* (1831). His *Discours parlementaires* were published in 16 volumes from 1879 to 1883.

**THINKING AND PROBLEM SOLVING.** Problem solving is one kind of thinking that has been studied quite frequently. The term thinking has many definitions, no one of which is satisfactory to everyone. Traditionally limited to an activity of human beings, the word implies an inner, more or less rational process (distinguished from other subjective activities, such as perceiving or recalling). Since thinking normally is considered to be a private activity, many observers say they are confident only that other people behave *as if* they were thinking. (It is also common to see pet dogs treated as if they were thinking.) However, the effectiveness with which an organism handles in-

formation sometimes can be observed directly by others. For objective study, therefore, thinking is treated by inference, being defined through evidence that the presumptive thinker has processed old data to yield information that is new to him.

When a person thinks, he processes information he already has learned and obtains a result that in some sense is new. Suppose, for example, he is asked to give the numerical value of the seventh power of five. After having multiplied  $5 \times 5 \times 5 \times 5 \times 5 \times 5 \times 5$  he may give the answer: 78,125. An appropriate operation—in this case, multiplication—apparently was carried out to obtain new information. Of course, if he had learned this specific result earlier, he would have been remembering rather than thinking as defined here.

Some define thinking as nothing more than learning or remembering. The view taken here is that one learns items of information and the operations employed in processing them; but the processing (or thinking) itself should be distinguished from learning at least provisionally.

Thinking involves simpler operations such as matching two items, such complex mathematical processes as integration, as well as many that are less rigorously logical. These processes vary from one thinker to another and from one problem to another. Imagine the differences that exist among processes involved in choosing moves in chess, in composing music, and in diagnosing appendicitis.

Thinking, as here defined, includes problem solving, decision making, creative thinking, and even dreaming. Since more is known about problem solving than about any of the other types of thinking, it will be the primary subject of this discussion. A problem exists whenever an individual seeks a means to any end. In solving the problem, a person processes information he already has or that he can obtain from the environment.

Experimental studies of problem solving are concerned primarily with what goes on as an individual reaches a goal, and with how achievement in problem solving can be varied experimentally; e.g., how the number of problems solved by a group in a given time varies with the size of the group. Achievement in problem solving has also been studied in terms of its correlation with such variables as general intelligence.

**Introspection.**—Systematic experiments on thinking (early 20th century) were of the introspective type. Thinking was conceived as a conscious process directly open to the introspection (*q.v.*) of the thinker. The experimental method was to ask people to describe their experience promptly as they tried to solve assigned problems.

The results of this straightforward and apparently obvious procedure cast doubt on the then common assumption that consciousness is a composition of what were called simple sensations, images, and feelings. The subjects, to be sure, mentioned such sensory or emotional contents; but most subjects far more prominently described experiences that they felt were unanalyzable into elementary sensations, images, and feelings. Among these were attitudes such as doubt, hesitation, or sudden illumination; and "imageless thoughts," noted simply as thoughts *of* or thoughts *about*, reported as having little or no sensory or imaginal content. Furthermore, such conscious occurrences seemed to the subjects often to be totally absent at critical turning points in their thinking, the solution of a problem appearing to have been made below the level of awareness (*see* ASSOCIATION, MENTAL).

These results were obtained independently by a group of men inspired largely by O. Külpe at the University of Würzburg in Germany (1901-07), by A. Binet in France (1903), and by R. S. Woodworth in the U.S. (1906). They indicated that thinking is neither completely nor faithfully mirrored in consciousness—that important aspects of the process are outside the range of introspective observation. Moreover, since disagreements between introspecting subjects could not be settled by an appeal to facts some psychologists held it necessary to discard introspection in all psychological research. To others, perhaps to most, the conclusion was that the possibilities of introspection had been greatly overestimated; but that within limits it may be useful, especially when combined with other methods.

**Implicit Muscular Activities.**—John B. Watson (*see* BEHAVIOURISM) led those who proposed to discard from psychology all reference to consciousness. Watson treated thinking as consisting of slight muscular movements, especially though not exclusively those involved in speaking. His view that thinking is implicit speaking led to attempts by others to record such movements with mechanical lever systems. These attempts were largely inconclusive, partly because the recording systems employed were too crude.

Electrical systems subsequently were used for more sensitive indication of muscular activity. Electrodes placed near a muscle will pick up minute but measurable changes in potential. With a vacuum tube amplifier, potential changes as small as one millionth of a volt were recorded on photographic film. L. E. Jacobson (1929–32) had subjects carry out tasks involving thinking while action currents from appropriate muscles were recorded. For example, subjects were instructed to imagine bending the right arm. Action currents were obtained from the right arm while the subjects were imagining this act, but not while they were imagining bending the left arm or while they were relaxing. Electrodes were attached to the tongue and lips while subjects imagined counting, telling the date, and so forth. The records of action currents were similar to those obtained when subjects were faintly speaking the same words or numbers. L. W. Max (1934–37) studied deaf-mutes, who normally use gesture language. When they were given problems to solve, action currents from the muscles of the fingers were found to be much larger and more frequent than those from normal subjects under the same conditions. During sleep, two- or three-minute bursts of activity were recorded from the same muscles in deaf-mutes. When awakened during such bursts, these subjects often reported that they had been dreaming; when awakened in the absence of such bursts, they were much less likely to report that they had been dreaming.

**Peripheral v. Central Theory.**—These results have been interpreted by some to support a peripheral theory of thinking. According to central theories, all activities necessary and sufficient for thinking occur in the brain. Peripheral theories, however, hold that implicit muscular activities together with perceptual changes to which they give rise form the necessary and sufficient condition, the brain simply mediating awareness of implicit movements. Most modern psychologists accept interpretations of implicit muscular activity that are consistent with central theory. Such movements are held to result from an overflow of central nervous activity as a by-product of thinking; or these movements are thought to reinforce central neural activity associated with thinking. Although brain-wave changes can be observed in people who say they are thinking (*see* ELECTROENCEPHALOGRAPHY), they cannot be used to indicate what a person thinks.

**Trial and Error.**—C. Lloyd Morgan (1894) questioned the widely accepted view that nonhuman animals can reason. Morgan held, for example, that his fox terrier learned to open a gate by raising the latch with his muzzle through trial and error: gradual elimination of errors and strengthening of the correct response through repetition. In a typical experiment by E. L. Thorndike (1898, 1911), a cat in a box was allowed to escape by making the correct response of pressing a lever, pulling a string, licking itself, and so on. His results led Thorndike to conclude that the animals showed only behaviour involving trial and error.

H. A. Ruger (1910) studied intelligent and educated adults working on complicated mechanical puzzles; he followed essentially the same procedures as Thorndike, supplemented with introspective reports from his subjects. Ruger reported a large amount of trial and error behaviour. He noted that many unsuccessful reactions often were retained after they proved to be useless; successful procedures often appeared without foresight and even without attracting the subject's notice; puzzles often were solved with little or no comprehension of principles. However, some of these people showed sudden improvement that coincided in most cases with introspective reports that the subject had seen the point of the puzzle.

**Insight.**—Emphasis on trial and error in problem solving was criticized by Gestalt psychologists, who stressed insight. W.

Köhler (1925) contended that Thorndike had artificially produced trial and error by selecting inappropriate problems. Thorndike's cats, for example, had to push levers, a normally uncatlike response that could be hit on only by chance. Köhler presented apes with problems in which elements necessary for solution were available and which required typically apelike responses. Though he reported considerable trial and error, Köhler stressed that the critical moment in the solution occurred when the ape seemed to grasp an appropriate relation; for example, when he saw a box he could climb to reach fruit suspended beyond his reach. Another ape was reported to have inserted one stick into another, insightfully using the tool to retrieve food that was too far from his cage to reach otherwise.

Max Wertheimer used the notion of insight to account for how (1945) Albert Einstein developed his theory of relativity. In a series of leisurely conversations Einstein described to Wertheimer successive partial insights that led him to think of the velocity of light as an invariant.

Modern Gestalt theory with respect to problem solving and thinking may be considered in terms of conscious experience or in terms of underlying brain processes. When a person is confronted with a problem, perceptual processes in the brain (and in consciousness) are held to interact with each other and with memory traces to result initially in "seeing the problem." This is said to set up stresses in the psychological field that lead to its reorganization, enabling the person to perceive the relations that solve the problem. Such reorganization tends to occur suddenly, although a series of progressive reorganizations may give the appearance of gradual solution (*see* GESTALT PSYCHOLOGY).

**Modern Behaviouristic Approach.**—Modern behaviourism, stemming from the work of Clark L. Hull (1943), approaches thinking through a complex system of notions that can only be suggested here. It is stated that any stimulus situation will be associated with a number of responses that differ in their probability of occurrence and hence form a hierarchy. The position of any response in this habit-family hierarchy will vary with how effectively it has been reinforced previously in similar situations (*see* LEARNING). Given a new problem, the hierarchy will determine the responses and the order of their occurrence. According to the notion of goal gradient, the closer (in distance or time) an organism is to a goal, the stronger its motivation will be; it will tend to choose the shorter of two paths. The ideas of goal gradient and of habit-family hierarchy suggest that the probability of a roundabout path being taken in solving a problem will vary inversely with the angle between the direct and roundabout paths. An organism that learns to make a given response to one stimulus will become increasingly likely to make the same response to similar stimuli (stimulus generalization). The probability of the response will vary directly with the similarity of the new to the original stimulus. Thus, a person with no screwdriver may readily use a fingernail file to tighten a screw; to pound a nail with no hammer he may exhibit much more trial and error before using the leather heel of his shoe.

**From Trial and Error to Insight.**—Harry F. Harlow (1949) studied the possibility that successful trial and error could lead to later insight. In a typical experiment, he confronted a monkey with two objects of different colour, size, and shape. If the monkey picked up the correct object, he found raisins or a peanut underneath. The position of the correct object was varied randomly from trial to trial until the monkey learned to choose it every time. The monkey was then confronted with a new pair of objects; and this procedure was repeated many times. The first such problems were solved by slow trial and error; each new problem was solved with greater efficiency until eventually the monkey showed what seemed to be perfect insight, solving a new problem of the same type in one trial. Similar results were obtained for monkeys with more complex problems and also for young children.

**Information Processing.**—A theory of problem solving quite different from those thus far described was advanced by Allan Newell, J. C. Shaw, and Herbert A. Simon (1958). The thinking human being is regarded as an information-processing system (*see*

INFORMATION THEORY). Such a system involves memories (stored symbolized information) that are interconnected by various ordering relations. The system operates on the memories according to a definite set of rules called a program. Explanation of observed problem-solving behaviour theoretically consists in constructing a program that will generate that behaviour. The writing of a program requires a precise language; and special so-called information-processing languages have been created for this purpose (see also MANAGEMENT SCIENCES: *Mathematics*).

Modern high-speed electronic computers work in what are called machine languages. They can, however, be provided with interpretive programs that enable them to handle these special information-processing languages. Thus a program written in an information-processing language can be run on a computer to determine the kinds of behaviour it will generate. This approach does not depend upon any analogy between the structure of a computer and that of the human brain; the computer is used as a tool to determine quickly whether the consequences of a program are consistent with the observed behaviour it is supposed to explain (see further COMPUTER).

If a program is to be more than an *ex post facto* explanation, it must not only generate the behaviour it was written to account for but also must predict the effect on behaviour of changing conditions.

Processes called algorithms will eventually solve some problems if a solution exists. A simple example of an algorithm is the process of opening a safe by trying all possible combinations. For some problems algorithms require too much time to be useful. There is not enough time for a man to choose his moves in chess, for example, by exploring all possible continuations of the game to termination.

A heuristic process is one that may solve a particular kind of problem but offers no guarantee. In an algebraic problem, for example, introduction of an auxiliary unknown may or may not lead to solution. For most problems only heuristic processes are available. Even with problems for which an algorithm is known, a heuristic process may be preferable because it requires much less time.

The Logic Theorist (a program written by Newell, Shaw, and Simon) can solve problems by discovering proofs for theorems in symbolic logic (*g.v.*). By using an appropriate interpretive program, the Logic Theorist was run repeatedly on a high-speed digital computer. In one experiment, the Logic Theorist succeeded in proving 38 of 52 theorems from the *Principia Mathematica* of Alfred North Whitehead and Bertrand Russell. The time required to construct a proof varied from less than a minute to more than 15 minutes. The success of the Logic Theorist depends on the effective use of heuristic methods. Similarly, the strategy and tactics of U.S. military forces in Vietnam during the 1960s were reported to have been guided by heuristic computer programs.

**THIOPHENE** is an organic sulfur compound that resembles benzene physically in that it is a colourless, water-insoluble liquid boiling at 84° C (benzene boils at 80°). It resembles benzene also in such chemical reactions as bromination, nitration and sulfonation, but differs in being more reactive. It has the molecular formula  $C_4H_4S$  (I).

Dyes, plastics, solvents, explosives and the like can be made from thiophene; however, they frequently are inferior to those made from benzene and uses have been slow in developing. One application is in the manufacture of pharmaceuticals such as the antihistaminic drug thenylene, of the structure

Certain thiophene derivatives occur in nature, one being "terthienyl" or dithienyl-thiophene, a blue solid found in the petals of marigolds. Another, more complex derivative is biotin, the growth-promoting factor in yeast, liver and eggs.

Although originally isolated from coal-tar benzene by V. Meyer (1883), thiophene is prepared more easily in other ways. A convenient laboratory synthesis is dry distillation of an intimate mixture of sodium succinate and phosphorus sulfide ( $P_4S_7$ ). Similarly, by heating a mixture of acetylacetone ( $CH_3COCH_2CH_2COCH_3$ ) and phosphorus sulfide, 2,5-dimethylthiophene (II) is obtained.

I

II

In the industrial manufacture of thiophene, mixtures of butane or butene and sulfur or sulfur dioxide are heated at 600° C. for short periods. Similarly, 2-methylthiophene and 3-methylthiophene are formed when pentane and isopentane, respectively, are treated in this way. The important radicals in the thiophene series are 2-thienyl (III), 2-thenyl (IV) and 2-thenoyl (V).

III

IV

V

A delicate test for thiophene is afforded by reaction with isatin and sulfuric acid. If thiophene is present, as in coal-tar benzene, an intensely blue solution of indophenin results. This reaction is not encountered with benzene. Others in this category are the reactions of thiophene with cyanogen bromide to yield bromothiophene and with acetyl chloride in the presence of titanium tetrachloride to yield acetothienone, the thiophene analogue of acetophenone. The thiophene analogue of phenol, 2-thienol, cannot be prepared by methods that are industrially successful for phenol but can be made from 2-thienyl-magnesium bromide by reaction with oxygen at 0° C. In contrast to phenol, thienol is quite unstable.

See H. D. Hartough, *Thiophene and Its Derivatives* (1952).

**THIRD DEGREE**, a slang term now in common usage in the United States and frequently employed in Great Britain, designates the use of force or duress by police and prosecuting authorities to extort information or confessions from persons in their custody. There are conflicting theories as to the origin of the term. Some assert that it was borrowed from the Russian police, who allegedly resorted to severe physical duress after the suspect failed to respond to cross-examination and confrontation. Others hold that it represents an ironic reference to the third masonic degree, that of master mason, which is conferred with considerable ceremony.

The methods of the third degree are many, including beatings, threats of violence, denial of food, drink, or rest to the person interrogated, prolonged questioning, and the like. The National Commission on Law Observance and Enforcement (1931) reported widespread use of such methods in the United States. Because such behaviour occurs in secret, it is impossible to determine accurately the extent to which it persists. Observers have expressed the opinion, however, that U.S. police now employ overt physical violence less frequently than at the time of the commission's report.

Since the last half of the 18th century the Anglo-American law has directed the exclusion of confessions obtained by force, threats, or tricks from criminal trials. The exclusion of such coerced or involuntary confessions is required by the 5th and 14th amend-

ments of the U.S. Constitution and by comparable provisions in state constitutions. See also CRIMINAL LAW: *Criminal Procedure*; EVIDENCE: *Privilege and Public Policy*. (F. A. A.)

**THIRTY-NINE ARTICLES.** The Thirty-nine Articles of Religion, together with the Book of Common Prayer to which they are usually appended, constitute the doctrinal formularies of the Church of England. Their origin lies in the Forty-two Articles drawn up by Archbishop Thomas Cranmer in 1553 "for the avoiding of controversy in opinions." These were partly derived from the Thirteen Articles of 1538, designed as the basis of an agreement between Henry VIII and the German Lutheran princes, which in turn drew from the Lutheran Confession of Augsburg of 1530 (see AUGSBURG CONFESSION). Cranmer desired to make all preachers subscribe to the Forty-two Articles, the general purpose of which was to rule out both Roman Catholic and Anabaptist doctrine while at the same time furthering Cranmer's aim of uniting German and Swiss Reforming opinions. The Marian reaction swept them away, and after the Elizabethan settlement the problem arose of providing a doctrinal platform for the established church. For the first few years Archbishop Matthew Parker's Eleven Articles temporarily served, but in 1563 the Canterbury Convocation drastically revised the Forty-two Articles, making use of the Lutheran Württemberg Confession of 1551-52. Its work, after further revision by royal authority, emerged as the Thirty-eight Articles. A final revision by Convocation in 1571 produced the Thirty-nine Articles, which were approved by the queen and imposed on the clergy. (See also ENGLAND, CHURCH OF: *The Reformation*.)

In form the articles resemble the many Protestant confessions of faith of the 16th century, dealing briefly with the doctrines accepted by Catholics and Protestants alike and more fully with points of controversy. Closer examination, however, reveals that (chiefly as a result of the 1563 revision) they are at many points studiously ambiguous, because the Elizabethan government wished to make the national church as comprehensive as possible, not only avoiding commitment to specifically Lutheran, Zwinglian, or Calvinist views but also leaving loopholes for nonpapal Catholicism. Thus differing interpretations of them survive, including an attempt by the Franciscan Franciscus à Sancta Clara (Christopher Davenport) in 1634 (renewed by J. H. Newman in his Tract 90 of 1841) to reconcile the articles with much of the teaching of the Council of Trent.

Although subscription to the articles is required of all clerics of the Church of England, it has rarely been demanded of the laity. Moreover it became a tradition that the formulary consisted largely of "articles of peace," statements not to be gainsaid but not having the same binding authority on conscience as dogmatic statements of revealed truth. This was legally recognized in 1865, after which clerical subscription was limited to a declaration that the doctrine of the Church of England, in both prayer book and articles, is "agreeable to the word of God," so that the acceptance of every statement in them is not required. Among other churches of the Anglican Communion their status varies. In the United States, the articles, in slightly modified form, are included in the prayer book of the Protestant Episcopal Church, but neither clergy nor laity is required formally to subscribe to them.

**THIRTY YEARS' WAR**, a conventional and largely misleading name for that part (1618-48) of the 50 years' struggle for the European balance of power (c. 1610-60) in which the Austrian Habsburgs and the German princes and cities were involved.

The usual picture of the Thirty Years' War, as painted by German historians and accepted uncritically by most English and American scholars, can be summarized as follows: (1) the war was one continuous struggle, fought almost exclusively on German soil, beginning with the Bohemian Revolt in 1618 and ending with the Peace of Westphalia in 1648; (2) it was the last and greatest of the Wars of Religion kindled by the German and Swiss Reformation of the 1520s, which the non-German powers, namely Denmark, Sweden, and France, together with the half-Spanish Habs-

burgs, exploited for political ends of their own; (3) it completely destroyed the German economy, leaving behind an impoverished near-desert which had lost one-third, one-half, or even two-thirds of its population; and (4) it dealt a mortal blow to the intellectual, moral, and artistic life of Germany.

Every one of these assertions can be challenged.

First, there was not one uninterrupted war, but about a dozen wars, fought at different times, in different parts of Europe, by different belligerents, for different aims, interrupted by years of truce or peace affecting different regions.

Second, the religious differences between the German Protestants and Catholics were indissolubly bound up with constitutional and political questions. While it is impossible to assess the ratio of religious, political, constitutional, and economic considerations which determined any particular move, religious questions, more often than not, merely provided ideological and propagandist grounds for very secular war aims and peace proposals. The involvement of non-German powers was due to the geographical position of Germany in the heart of Europe and to a number of factors which would have remained even if there had been no religious conflict. The head of the Austrian Habsburgs, for instance, king of Bohemia and of Hungary and ruler of his house's ancient patrimony on the Danube, in the Alps, and on the Upper Rhine (see HABSBERG), was also Holy Roman emperor, nominal sovereign over the whole *Reich* or empire, that is, over all the other German princes; and the German princes were anxious to resist any expansion of his authority. The emperor's Spanish Habsburg cousins, at the same time, to whom he was closely bound by family ties, were nominally members of the empire insofar as they held Franche-Comté and the Netherlands (though the northern Netherlands had been in open revolt against Spain since 1572); and Spain was furthermore in dispute with France over certain Italian principalities over which the emperor was nominally overlord. The king of Denmark likewise was a member of the empire in his capacity as duke of Holstein and, eventually, as director of the Lower Saxon "Circle" of the empire. The Hohenzollerns of Brandenburg, electors of the empire, were vassals not only of Bohemia for certain fiefs in Silesia but also of Poland for their Duchy of Prussia. Finally, Sweden's Baltic policy led to encroachment on the Pomeranian part of the empire. These and other dynastic or territorial questions provided reasons or pretexts for German princes to call in foreign powers as well as for foreign powers to take sides in German or so-called German affairs.

Finally, the social, economic, and cultural impacts have been misinterpreted. Seen in their true perspective, they will be found on a par with the results of every war.

The present article is divided into sections as follows:

#### I. Survey of Political Aspects

1. Western Europe
2. Northern Europe
3. Eastern Europe
4. Germany
5. Great Britain

#### II. Survey of Religious Aspects

#### III. Events

1. War of the Jülich Succession (1609-14)
2. Bohemian and Palatine War (1618-23)
3. Struggle for the Graubünden (1620-39)
4. Swedish-Polish War (1621-29)
5. Danish War (1625-29) and the Edict of Restitution
6. War of the Mantuan Succession (1628-31)
7. Swedish War (1630-35) and the Peace of Prague
8. War of Smolensk (1632-34)
9. French and Swedish War (1635-48)
10. Swedish-Danish War (1643-45)
11. Peace of Westphalia (1648)
12. Franco-Spanish War (1648-59)
13. First Northern War (1655-61)

#### IV. German Civilization

1. The Population
2. Economic Life
3. Literature and the Arts

#### V. Conclusion

Sections I and II allude to matters elucidated in Section III. Throughout the article the new style is used for dating, even where English, Swedish, or Russian historians use the old.

## I. SURVEY OF POLITICAL ASPECTS

**1. Western Europe.**—The uniting aspect of the period, in the history of Western Europe, is the struggle of the French monarchy and of the Dutch Republic, or United Provinces of the Netherlands, against the two branches of the House of Habsburg, Spain and Austria. (*See FRANCE: History; NETHERLANDS, THE: History.*)

The later wars of aggression, waged by Louis XIV of France and by Napoleon I, tend to obscure the fact that from the middle of the 16th to the middle of the 17th century France was the victim of a deliberate policy of encirclement by the Habsburg powers. In the south, possession of Roussillon gave Spain a firm foothold north of the Pyrenees. In the southeast, the Republic of Genoa was a Spanish satellite, and the Duchy of Milan was Spanish territory. Genoa and Milan guaranteed a short and safe line of communication from Spain to Austria proper as well as to the Spanish possessions along the eastern borders of France, namely Franche-Comté (contiguous with Austrian Alsace) and the Low Countries (Luxembourg, Hainaut, and Artois on the French frontier, with Flanders, Brabant, and the rest of the Netherlands in their immediate hinterland). After the successes of the Dutch rebellion, from 1572, the overland route from Genoa to Brussels was the more important because the final link of the chain around France had snapped after the death of Mary I of England (1558): the fate of the Armada (*q.v.*) in 1588 had demonstrated the insecurity of the northern sea route from Spain to the Netherlands.

The breaking of this Habsburg stranglehold was the foremost task of French statesmanship. It was first undertaken when Henry IV of France resisted the attempt by the Habsburgs, in 1609, to acquire Jülich-Cleves-Mark-Berg (*see* JÜLICH), as this attempt threatened to deal the deathblow to the independence of the United Provinces of the Netherlands and to lay France's northern frontier open. Henry's policy, interrupted by his assassination (1610) and by the pro-Spanish appeasement of the French regency under Marie de Médicis, was resumed by Cardinal de Richelieu (*q.v.*), in power from 1624 until his death in 1642, and was continued by his successor, Cardinal Mazarin (*q.v.*). France, at first too weak to wage open war against the Habsburgs, began by making treaties with powers hostile to them (or to their satellites in Germany or in Eastern Europe), namely with the United Provinces (1624), with Sweden (1631), and with Russia (1632); but the defeat of the United Provinces' ally Denmark (Peace of Lübeck, 1629), the withdrawal of Russia (Peace of Polyanov, 1634), the defeat of the Swedes (Battle of Nördlingen, 1634), and the defection of Sweden's German allies (Peace of Prague, 1635) forced Richelieu to declare open war on Spain (1635), after which Catalonia and Portugal (1640) and, later, Great Britain (1657) also joined the French camp. The modest French military successes were surpassed at the conference table: the Peace of Westphalia (1648) established the preponderance of France and France's allies throughout Central and Northern Europe; the formation of the League of the Rhine (1658) gave France a decisive voice in the affairs of the empire; and the Peace of the Pyrenees (1659) enlarged and secured France's frontiers and marked the end of Spain as a great power.

For the Dutch, the period of the Thirty Years' War forms part of their Eighty Years' War against Spain (1568–1648). The 12 years' Truce of Antwerp (April 9, 1609) can now be seen as the *de facto* recognition of the independence of the United Provinces; but contemporary Dutch statesmen foresaw that the Spanish crown would not easily abandon the hope of reducing the rebellious heretics and recovering its richest European province. In fact, Philip IV of Spain, whose accession in 1621 coincided with the expiry of the truce, immediately renewed the war. But whereas at the outbreak of the rebellion Spain had been the leading maritime, commercial, and colonial power, superiority in all these spheres had passed to the Netherlands. The only weakness of the maritime republic was its lack of land forces; but the States-General had no difficulty in enlisting foreign mercenaries or paying subsidies to foreign princes. Whereas the interest of Spain demanded the localization of every conflict so that resources might be concentrated against the Dutch, the interest of the Dutch was

served best by extending the war so as to engage Spain's power away from their borders. Religious and constitutional affinities gave the Calvinist Dutch republicans additional zest in their support (1) of the Calvinist elector John Sigismund of Brandenburg in his struggle for Jülich; (2) of the semirepublican nobles of Bohemia in their fight against Austrian absolutism; and (3) of the generals who, from 1621, continued the Bohemian War, nominally on behalf of the Calvinist elector Frederick V of the Palatinate. But practical political considerations made the United Provinces the focal point of every anti-Habsburg coalition: the Franco-Dutch Treaty of Compiègne (June 20, 1624) was the prelude of the Treaty of The Hague (1625), which effectively brought Denmark into the war against the emperor Ferdinand II; and after Denmark's defeat, Dutch diplomacy and subsidies aided Richelieu in enlisting Gustavus II Adolphus of Sweden as the military champion of the anti-Habsburg cause (1630–32).

From the middle of the 1630s the French superseded the Dutch as leaders of the anti-Habsburg struggle. The conquest of Alsace and of Breisach by France's protégé Bernhard (*q.v.*) of Saxe-Weimar in 1638 and the secession of Portugal in 1640 shook Spain into preferring to come to an arrangement with the Dutch; and the latter, having smashed the Spanish Navy in the English Channel (1639) and off Pernambuco (1640) and thereby put an end to Spanish overseas expansion, now considered Portugal, with the Portuguese colonial empire, a greater rival to their mercantile interests than Spain. Disregarding the alliance with France which they had made in 1635, the Dutch on Jan. 30, 1648, signed a separate peace with Spain.

The Eighty Years' War of the Dutch is outlined in the article NETHERLANDS, THE: *History*.

**2. Northern Europe.**—Viewed from Northern Europe, the first half of the 17th century comprises the attempts of the two Scandinavian kingdoms, Denmark and Sweden, to obtain what the diplomatic language of the time called the *dominium maris Baltici* (lordship of the Baltic Sea); *i.e.*, the possession of the leading Baltic ports through whose customs sheds the raw materials of the Polish and Russian hinterlands found their way into the west.

Denmark's repeated attempts to overpower Sweden failed, and the Danish outposts in the eastern Baltic were lost. King Christian IV's attempts to make himself supreme in Lower Saxony by acquiring the German bishoprics of Bremen, Verden, Minden, and Hildesheim led to the Danish War (1625–29), in which the superior generalship of his adversaries outweighed the subsidies granted to him by the Dutch and the British. The Peace of Lübeck (1629) finished Denmark as a European power of consequence.

Denmark's decline was emphasized by the simultaneous rise of Sweden. The Peace of Knäred (1613) made only transitory concessions to Christian IV of Denmark, who had attacked Sweden in 1611. Thenceforward King Gustavus II Adolphus systematically began to close the ring of Swedish possessions round the Baltic. After preliminary gains at the expense of Muscovite Russia, whose access to the Baltic he closed (1617), he successfully attacked the Baltic provinces of Poland and of Poland's vassal Prussia (1621–29). Besides pursuing this Baltic ambition, he may also have been aspiring to supplant his Catholic cousin, Sigismund III Vasa, on the Polish throne. Any such design, however, had to be abandoned: on the one hand the Swedish nobility objected to it; on the other, the king's Baltic policy was challenged by the advance of imperial armies along the southern shore from the west, which drew him into intervening in German affairs. The Swedish-Polish Truce of Altmärk (1629) was followed by alliance with France (Treaty of Bärwalde, Jan. 23, 1631).

The alliance with France survived the death of Gustavus Adolphus and remained the sheet anchor of his successors' position until Sweden's collapse as a great power (1721). Sweden reaped the fruits of this policy; first in the Peace of Brömsebro at the end of the Swedish-Danish War of 1643–45; then in the Peace of Westphalia (1648); and finally in the Peace of Roskilde (1658), with Denmark, in the course of the First Northern War. By the end of this period Sweden had achieved the *dominium maris Baltici*.

**3. Eastern Europe.**—The first half of the 17th century also embraces the first attempt by Poland to force Orthodox Muscovy (Russia) into the orbit of Latin Christianity as well as the first attempt on the part of the House of Romanov (*q.v.*) to enter the comity of Western Europe. Poland, tied to the Habsburgs by religion and tradition, hostile to Sweden by religion and dynastic rivalry, and implacably hostile to Muscovy by history and religion, exploited the "troubles" which convulsed Russia after the death of Boris Godunov (1605). The experiment of ruling Russia through a Polish puppet, the first False Dimitri (*q.v.*), failed in 1606, when the usurper succumbed in an outbreak of Russian nationalism and Orthodox fanaticism. But Poland came nearest to making Russia a satellite when in 1610 Sigismund III had his son, the future Wladyslaw IV of Poland, elected as tsar: the Polish dictatorship in Moscow lasted two years.

In 1609, the first Russo-Swedish alliance had been concluded by the tsar Vasilii III Shuiski; and despite Sweden's later aggressions the new Romanov dynasty (from 1613) continued to regard Sweden as Russia's natural ally against Poland. England and the United Provinces acted as intermediaries at the Russo-Swedish Peace of Stolbova (1617), and 13 years later French envoys brought about Muscovy's indirect support of Gustavus Adolphus' war in Germany. Russia, however, did not want to be involved directly in Germany, and the Russo-Polish War of Smolensk (1632-34) remained a sideshow. After the death of Gustavus Adolphus, Swedish-Russian relations cooled off, as the Swedish chancellor Axel Oxenstierna correctly assessed Russia as potentially more dangerous than Poland.

The Russo-Polish Peace of Polyanov (1634), which included Wladyslaw IV's final resignation of his claim to the Russian throne, freed Poland to resume hostilities against Sweden and, by thus tying down Swedish troops, contributed to the Swedish disaster at Nördlingen.

**4. Germany.**—All these European conflicts affected Germany more often and more deeply than any of the other contestants. Germany was the only country where the Reformation had resulted in a permanent split into three religious factions—Catholic, Lutheran, and Calvinist. As these religious divisions largely marched with political frontiers, they were sustained and aggravated by dynastic rivalries, such as that between the Catholic Wittelsbachs in Munich (Bavaria) and the Calvinist Wittelsbachs in Heidelberg (the Palatinate), or that between the Calvinist Kassel branch and the Lutheran Darmstadt branch of the House of Hesse. In turn, these political and religious dissensions were partly exacerbated and partly overlaid by constitutional problems: the Holy Roman emperor, a Habsburg and a Catholic, wanted to establish monarchical absolutism in the empire; the electors, Catholics and Protestants alike, wanted to maintain what they called the "electoral preeminence" in the empire's affairs; and lastly, the other princes wanted to overthrow the ascendancy of both the emperor and the electors, so as to obtain complete freedom of action for themselves.

Each of the rivals found it easy and profitable to call in some foreign power. On the whole, the emperor relied on his Spanish cousins; the Protestant towns and smaller princes relied on Sweden, on France, and on the Dutch; Catholic Bavaria, with its satellites Cologne, Liège, Münster, Paderborn, and Hildesheim, usually blackmailed the emperor, while inclining to France and opposed to Spain; Lutheran Saxony disliked all foreign entanglements, but regarded the Calvinists as worse than the Catholics and generally found it most profitable to side with the emperor (since repeated endeavours to rally a neutralist "third force" never succeeded); and Calvinist Brandenburg was weak and irresolute until 1640, when Frederick William, "the Great Elector," began to play off emperor, Swedes, Dutch, Poles, and French with such skill that by 1660 he had raised Brandenburg-Prussia to the rank of a great German and minor European power.

**5. Great Britain.**—From the death of Queen Elizabeth I (1603) to the passing of the first Navigation Act by Cromwell's Parliament (1651) Great Britain's influence upon European affairs was negligible. The European policy of the government was vacillating between Spain, France, and the United Provinces, while

Parliament and public opinion were enthusiastically anti-Spanish but unwilling to transform brave words into hard cash.

James I originally wanted to continue Elizabeth's pro-French and pro-Dutch policy but assented to peace with Spain (1604). In 1613 he gave his daughter Elizabeth in marriage to Frederick V of the Palatinate, leader of the Protestant anti-Habsburg faction in Germany; but twice, in 1617 and in 1623, he tried to obtain a Catholic Spanish Habsburg princess for his son Charles before betrothing him, in 1624, to a Catholic French Bourbon.

James had at least not dissuaded his son-in-law from accepting the Bohemian crown (1619), but his dislike of the Czech nobility's republican sympathies and religious radicalism, combined with his desire to appease the Spaniards, prevented him from giving tangible support to Frederick during the war in Bohemia. It was only when Frederick had lost the Palatinate and when the Spanish marriage project had collapsed that a cautious parliamentary grant for the preparation of war against Spain gave expression to the English public's lively sympathy for the Protestant cause. An expedition to the Palatinate was hopelessly bungled.

Charles I, on succeeding his father, undertook the war against Spain and also associated himself with the Dutch in the Treaty of The Hague (Dec. 9, 1625) for the support of Christian of Denmark against the emperor and the Catholic League in Germany. But the naval expedition against Cádiz (1625) was a failure; and Charles failed to pay Denmark the promised £360,000 per annum, after the first installment of £46,000. Soon afterward, he squandered ships, troops, and money on the disastrous expedition of 1627 to help the Huguenot rebels of La Rochelle against his brother-in-law Louis XIII of France. Thereafter Charles's devious foreign policy was hampered by lack of funds, which forced him to conclude peace both with France (1629) and with Spain (1630), and by lack of interest in foreign affairs on the part of his most capable adviser, Strafford. In 1636 and again in 1641 Charles offered to the Habsburgs an alliance against the Dutch in return for the restoration of the Palatinate to his nephew Charles Louis; but the Habsburgs declined this offer because Bavaria objected to it. Richelieu likewise in the same years preferred for France an understanding with Bavaria to a possible rapprochement with England.

## II. SURVEY OF RELIGIOUS ASPECTS

Religious issues were insolubly interwoven with political and constitutional problems. For Germany the whole question stemmed from the Peace of Augsburg (*q.v.*) of 1555, a compromise between the Catholic and Lutheran Estates (members) of the empire. Neither party was satisfied, neither meant to abide by it. It fixed the religious frontiers as they had existed in 1552; *i.e.*, at the lowest ebb of Protestant fortunes. It gave the sovereign lay princes the right to change with their own religion that of their subjects; but it prohibited any Catholic bishopric or free city from adhering in future to the Lutheran creed. It expressly excluded Calvinists from the toleration granted to Lutherans. Above all, it failed to lay down any criteria by which the many doubtful points might be interpreted, or to create any machinery to enforce its observance.

One of the many points left in suspense by the Peace of Augsburg concerned the right of the Protestant gentry in town and country under Catholic sovereigns to keep Protestant pastors and hold Protestant services. This issue played a part in the revolts of the Austrian and Bohemian nobility against their Habsburg overlords, which began in 1609 and ended with the Bohemian War in 1620. The ecclesiastical reservation which forbade the "reform" of Catholic bishoprics prevented Cologne from turning Protestant together with its archbishop, Gebhard (*q.v.*) in 1583. Gebhard's deposition was the basis of the greatness of the House of Wittelsbach: Bavarian princes held the archbishopric of Cologne continuously from 1583 to 1761, the bishoprics of Hildesheim and of Liège almost uninterruptedly throughout the same period, and the bishoprics of Paderborn and of Münster with but few more interruptions. Thus the undisputed leadership of Catholic Germany by the Wittelsbach Maximilian I (*q.v.*) of Bavaria was grounded on the preeminence of his house not only in the south

but also in the northwest of Germany, where Jülich and Berg in the hands of his brother-in-law further fortified his house.

The distribution of the religious parties in the empire during the first half of the 17th century, according to be it understood, to the sovereign's choice of religion, was approximately as follows. The whole of northern, northeastern, and central Germany, with the exception of the bishopric of Hildesheim and the abbey of Fulda, was Protestant. Northwestern, western, and southeastern Germany, with the exception of the Rhenish Palatinate in the west, was Catholic, as were all the Habsburg dominions (Austria and Tirol, Bohemia-Moravia and Silesia, a portion of Swabia). Württemberg in Swabia, Ansbach and Bayreuth in Franconia, and nearly all the free cities, even those in otherwise Catholic districts, adhered to the Protestant faith. The nobility and townspeople in Bavaria and the Habsburg countries, nearly all of whom had been Protestants, had been recatholicized or expelled by c. 1625.

The historian must not doubt the strength and sincerity with which the champions of the contesting factions and their humblest followers believed in the exclusive truth of their church: the emperor Ferdinand II, Maximilian of Bavaria, Tilly, and Richelieu were devout Catholics; Gustavus Adolphus, Bernhard of Weimar, the electors of Brandenburg, Saxony, and the Palatinate were unswerving Protestants; Wallenstein is perhaps the only personality of note who seems to have been entirely indifferent to religious distinctions, astrology having largely supplanted Christianity as his creed. However, motives other than religious zeal were the factors determining political allegiance.

Pope Urban VIII and the cardinals Richelieu and Mazarin were unbending in their opposition to Catholic Spain and to the Catholic emperor. The Lutheran elector of Saxony and the Lutheran landgrave of Hesse-Darmstadt were firm adherents of the emperor so long as circumstances permitted. Lutheran Saxony and Catholic Bavaria were consistently anti-Spanish and anti-Swedish. Calvinist Hesse-Kassel was Lutheran Sweden's most reliable ally and, together with Bavaria, mostly pro-French. The struggle for the Baltic brought the Lutheran Gustavus Adolphus into conflict with Orthodox Russia, with Catholic Poland, and with Lutheran Denmark; but his fight in Germany made him the ally of Catholic France and of Orthodox Russia. Maximilian of Bavaria extended his power at the expense alike of the Lutheran cities in Swabia and in Franconia, of the Calvinist elector Palatine, and of the Habsburg emperor, and did so mostly in conjunction with Lutheran Saxony and Catholic France. The bishops of Würzburg and of Bamberg were the first to abandon the Catholic interest at the peace congress of Münster. Protestant as well as Catholic princes, prelates, and cities were susceptible to French subsidies. Of none of the belligerents can it be said that religious motives were responsible for any major decision. The secret debates (1629-30) in the Swedish council about entry into the war are revealing: the security and defense of Sweden and the conquest of Germany were declared the war aims; the king was expressly warned against speaking of a war of religion since France might take umbrage.

The suppression of Protestantism by Ferdinand II in Austria and in Bohemia and by Richelieu in France was undertaken mainly on political considerations. The Protestants not only infringed the spiritual unity of the country (a tenet still held by every government) but also were the chief opponents of royal absolutism and, not without cause, were suspected of republican tendencies on Dutch and Swiss models. Their defeat therefore paved the way for that spiritual and administrative uniformity which became the hallmark of 17th- and 18th-century monarchy.

Similarly, the contest of the emperor against the Protestant princes and cities was to a large extent a contest to decide whether the empire was to be a monarchy, with the emperor at its head and the princes as his vassals, or a federation of more or less independent princes, with the emperor as its titular president. So long as Ferdinand II was willing to concede to the six electoral princes their traditional prerogatives in the government of the empire, these electors (including Lutheran Saxony and Calvinist Brandenburg) sided with him against the lesser princes. When Ferdinand in 1629 unmasked his real intentions by the Edict of Restitution, the electors, led by Catholic Bavaria, turned against

him. The Peace of Westphalia brought about the triumph of the lesser princes, with whom the electors now identified themselves against any recurrence of imperial centralism.

In fact, the Peace of Westphalia proved the interdependence of the problems, religious and constitutional, political and economic, which again and again were used as interchangeable counters. The recognition of the adherents of the Reformed (Calvinist) religion as being of equal right with those of the Lutheran faith was largely a by-product of the dispute over Pomerania between Brandenburg and Sweden. The emperor sacrificed the North German bishoprics to the Protestant claimants (Sweden, Brandenburg, Saxony, Mecklenburg, and Brunswick) and Alsace and the bishoprics of Metz, Toul, and Verdun to France; and in return Sweden and France renounced their claims to Austrian territory in Silesia and in Swabia respectively and assented to the exclusion of the Austrian Protestants from the treaty's clauses on restitution and toleration. The attitude of the Catholic princes to Pope Innocent X's protest against any formal agreement with the Protestants is characteristic of the trend toward excluding denominational considerations from political decisions: the first secret intimation which the nuncio gave to the emperor and to the Catholic princes in November 1647 was answered with evasive excuses; and the formal protocol handed over on Christmas Eve did not even receive an answer from any prince, temporal or ecclesiastical. A special "anti-protest clause" in the peace treaty was signed by all parties; it declared Innocent's condemnation of the peace invalid and ineffective and thus demonstrated the complete emancipation of secular politics from ecclesiastical tutelage. The religious questions left unanswered by the Peace of Augsburg in 1555 were solved in 1648 in the modern spirit of the "reason of state."

### III. EVENTS

**1. War of the Jülich Succession (1609-14).**—The settlement which the Peace of Augsburg had formulated for Germany was shaken in 1607-08 when Maximilian I of Bavaria annexed and recatholicized the Lutheran city of Donauwörth. Some of the German Protestant states concluded a military alliance, the Union, on May 14, 1608. The death of Duke John William of Jülich on March 25, 1609, opened a crucial question of succession, over which war broke out. On July 10, 1609, a Catholic military alliance, the League, was formed.

The wealth of John William's lands, Cleves, Jülich, Mark, and Berg, and their strategic position attracted not only the powerless legitimate heirs, namely John Sigismund of Brandenburg and Wolfgang Wilhelm of Palatinate-Neuburg, but also every powerful neighbour. The Habsburgs wished to install an Austrian prince, who would have placed the lands at the disposal of the Spaniards in their struggle with the Dutch and would incidentally have counteracted the predominance of Bavaria in northwestern Germany. France, the United Provinces, and England naturally objected to any strengthening of the Spaniards in that region. The assassination of Henry IV of France (May 14, 1610) prevented the war from becoming a European contest, though Spanish, Austrian, and Dutch troops repeatedly invaded the duchy in pretended support of one or other of the heirs. The Protestant Union, which John Sigismund had joined by turning Calvinist, and the Catholic League, of which Wolfgang Wilhelm had become a member by entering the Roman Church and marrying a sister of Maximilian, brought about a compromise which excluded all foreign claims (Oct. 24, 1610) and led to the partition of the inheritance between Brandenburg and Neuburg (Treaty of Xanten, Nov. 12, 1614).

**2. Bohemian and Palatine War (1618-23).**—This war began with the insurrection, in 1618, of the Bohemian and Austrian Estates against the future emperor Ferdinand II (*q.v.*), whose intention was to impose absolutist rule and to enforce the Catholic Counter-Reformation (*see* AUSTRIA, EMPIRE OF; BOHEMIA). The Bohemian nobles toyed with the idea of setting up a republic in order to secure the support of the Dutch but eventually, in August 1619, elected as their king the elector Frederick V of the Palatinate in the hope of obtaining the aid of the Protestant Union and Great Britain. Their expectations proved fallacious. Frederick failed to discipline the haughty Bohemian nobles or to rally the Bohe-

mian townsmen and peasants (whom he did nothing to relieve from harsh oppression by their feudal lords) and was abandoned by his German allies as well as by his father-in-law, James I of Great Britain. Ferdinand, although in a very weak position, succeeded in buying the support of Maximilian of Bavaria and the Catholic League, at a heavy price in money and land. In a campaign of a few months the League's troops under Johann Tserclaes von Tilly (*q.v.*) crushed the Austrian Estates and broke the rule of Frederick in the Battle of the White Mountain, near Prague (Nov. 8, 1620). The conquest of Glatz (Kłodzko) on Oct. 25, 1622, completed the subjugation of the lands of the Bohemian crown.

In the meantime the Spaniards from their bastions in Luxembourg and in Franche-Comté had since 1620 been overrunning the Rhenish Palatinate, where Tilly joined them in 1622, after he and Maximilian had in 1621 subdued the Upper Palatinate (north of Bavaria and west of Bohemia). Tilly also overcame the badly co-ordinated actions of several German princelings and generals who, in the pay of the United Provinces, Denmark, and England, still upheld Frederick's cause, notably Ernst von Mansfeld (*q.v.*) and Christian (*q.v.*) of Brunswick. Whereas the Protestant Union had dissolved itself (May 1621), Lutheran Saxony, which had never adhered to the Union, was won over to the emperor by the offer of Lusatia. The defeat of Christian of Brunswick by Tilly at Stadtlohn (Aug. 6, 1623) left the situation as follows: the emperor was in undisputed control of his Austrian and Bohemian ter-

ritories; Maximilian of Bavaria, who was created elector, had become the leading power in southern and northwestern Germany; the Spaniards were in possession of the Rhenish Palatinate; and Frederick was a landless exile, living on the bounty of the Dutch.

**3. Struggle for the Graubünden (1620-39).**—The Valtellina (*q.v.*), leading from the northern frontier of the Duchy of Milan through the Alps toward Tirol, opened the shortest and safest land route between Spanish Italy and the Austrian territories in Germany, whence the Spaniards could reinforce their troops in the Netherlands and in the Palatinate. It belonged to the Graubünden (*q.v.*), or Grisons, a union of leagues in loose relations with the Swiss. Spain and Austria obviously wanted to bring the union's lands under their own control; France and Venice naturally opposed the forging of this link, which would have completed encirclement of both of them by the Habsburg powers. The political and military issues were here poisoned by religious, personal, local, and clannish rivalries, of which Georg Jenatsch (*q.v.*) was the stormy centre. A Spanish occupation of the Valtellina (1620), reinforced by an Austrian incursion into the other territories of the Graubünden (1621), provoked French and Venetian protests which led to the nominal "deposit" of the Valtellina in the hands of the papacy (1623)—in fact a veiled means of prolonging Spanish control there. Then Richelieu ventured on the first French occupation of the Graubünden (1624-26); but the internal weakness of

France, where Richelieu's regime was challenged on the one hand by the pro-Spanish faction of Catholic zealots (the *Parti Dévot*) and on the other by the Huguenots, made it impossible to maintain this indirect attack on Spain. The Treaty of Monzón (1626) made the Graubünden into a sort of Franco-Spanish protectorate, with papal troops in occupation. During the War of the Mantuan Succession the Habsburgs again overran the country (1629-31). A final French occupation (from 1635) was ended in 1639 by a reaction of the Graubünden against the French. Eventually the Peace of Milan (Sept. 3, 1639), between Spain and the Graubünden, brought the country into virtually complete dependence on Spain.

**4. Swedish-Polish War (1621-29).**—From 1611, Gustavus Adolphus had taken advantage of the "Time of Troubles" and its aftermath in Muscovite Russia (*see* RUSSIAN HISTORY); and by the Peace of Stolbova (1617) he had acquired Karelia and Ingria, which together constituted the land bridge between Swedish Finland and Swedish Estonia, so that the Gulf of Finland was converted into a Swedish lake. He then turned against Poland (1621). His conquest of Livonia gave him Riga, the chief Baltic port (though the Swedish nobles possessed themselves of the largest landed properties in the country, to the detriment of the Swedish crown); and from the Duchy of Prussia, Poland's vassal, he took the ports of Memel and Pillau, the latter commanding the approach to Königsberg. Sweden's position in the Baltic, however, was eventually endangered by the course of the Danish War, as the imperial general Wallenstein (*q.v.*) conquered Mecklenburg (with the ports of Wismar and Rostock) and threatened moreover to conquer Pomerania; and in summer 1628 Swedish forces were sent to help the port of Stralsund, which Wallenstein was besieging. Finally the Truce of Altmark (Sept. 25, 1629) was concluded between Sweden and Poland, largely thanks to French mediation. Livonia and the Prussian ports were left in Sweden's possession.

**5. Danish War (1625-29) and the Edict of Restitution.**—Christian IV (*q.v.*) of Denmark had observed strict neutrality during the Bohemian War despite repeated Dutch attempts to enlist his help on behalf of Frederick of the Palatinate. In 1624, however, he began to contemplate offensive action. His motives were rivalry of Sweden in the Baltic regions and the wish for Danish supremacy in the estuaries of the Elbe and Weser. The king's election, in spring 1625, as director of the Lower Saxon "Circle" of the empire furnished him with the legal pretext for interference in Germany. The Treaty of The Hague (Dec. 9, 1625), in the negotiation of which the British statesman George Villiers, 1st duke of Buckingham, played a major part, promised British and Dutch subsidies for a military effort by Denmark on Frederick's behalf, in cooperation with the German generals who had already tried to uphold the latter's cause; and this Protestant coalition could expect the sympathy of the Habsburgs' other enemies—Prince Gabriel Bethlen (*q.v.*) of Transylvania, the Ottoman Turks, and also Catholic France.

The coalition's plan seems to have envisaged a fourfold advance: Christian of Brunswick was to overpower the Wittelsbach bishoprics and duchies in Westphalia and in the lower Rhineland; Christian IV of Denmark was to make himself master of Lower Saxony; Ernst von Mansfeld, generalissimo of the coalition, was to press forward into Bohemia, Silesia, and Moravia; and Bethlen was to sally forth from Hungary and join forces with Mansfeld.

On the opposite side were ranged the veteran troops of the Catholic League under Tilly, who was to deal with Christian of Brunswick and with Christian IV of Denmark; and the Imperial Army of Wallenstein, who was to repel Mansfeld and Bethlen.

On both sides the generals were on bad terms with one another and never effectively coordinated their efforts. But Tilly and Wallenstein had the advantage of fighting on interior lines and could therefore tackle their adversaries in turn. The coalition, on the other hand, was weakened by the faithless policy of Charles I of Great Britain, who failed to honour his financial obligations and let Buckingham embark on a foolish expedition against France in aid of the Huguenots of La Rochelle (June-November, 1627). Wallenstein forced Mansfeld out of northern Germany (Battle of

ATROCITIES COMMITTED BY BOTH CATHOLIC AND PROTESTANT FORCES INSPIRED FRENCH GRAPHIC ARTIST JACQUES CALLOT (1592-1635) TO MAKE TWO SETS OF ETCHINGS, THE "SMALL" AND THE "LARGE" "MISÈRES DE LA GUERRE" (1633), FROM WHICH THE ABOVE PRINTS COME: (TOP) A MASS EXECUTION; (BOTTOM) LOOTING AND BURNING A VILLAGE

Dessau, April 25, 1626); and Mansfeld, though he held a strong position in Silesia, neither made full use of anti-Habsburg movements (apart from discontent in the Bohemian lands, a peasants' revolt broke out in Austria in May) nor effected a junction with Bethlen and the latter's Turkish auxiliaries. Wallenstein outmaneuvered Bethlen, and Mansfeld died on his way to Venice (Nov. 29, 1626), whence he hoped to receive fresh subsidies. Isolated Danish troops maintained themselves in Silesia until the autumn of 1627, when Wallenstein overwhelmed them.

Meanwhile Tilly was favoured by the untimely death of Christian of Brunswick (June 16, 1626) and by the military incompetence of Christian IV of Denmark. The Danish Army suffered a crushing defeat in the Battle of Lutter (Aug. 27, 1626). In 1627 Tilly pursued the beaten Danes into Holstein; and Wallenstein, who joined him, continued the pursuit into Jutland. Mecklenburg (*q.v.*), whose dukes had sided with Christian, was given by the emperor to Wallenstein, who immediately set about obtaining bases on the Baltic for an imperial navy. His attempt to add the Pomeranian port of Stralsund to his Mecklenburg ports of Wismar and Rostock led to the intervention of Gustavus Adolphus.

Wallenstein's contact with maritime affairs changed his whole outlook. His first sight of large river barges on the Oder had made him believe that they were oceangoing capital ships; but he now realized the importance of sea power and overseas trade and reassessed the political position which the emperor might take up with regard to the Hanse towns, Denmark, the Netherlands, England, and Spain. Denmark, which he wished to draw into the emperor's interest, profited by his mediation: at the Peace of Lübeck (May 22, 1629) Christian IV had only to renounce further participation in the affairs of the empire.

The defeat of the anti-Habsburg coalition raised the position of the emperor to its greatest height since Charles V's victory over the League of Schmalkalden in 1547. Ferdinand II's Edict of Restitution (March 6, 1629), prescribing the recovery by the

Catholics of all ecclesiastical lands in which Protestantism had been established since 1552, was more than an act of reparation of the damage suffered by the Catholic Church since Luther's time: it was an unambiguous assertion of the imperial prerogative in all matters pertaining to the constitutional structure of the empire. At the Electoral Diet of Regensburg (1630) the opposition, led by Lutheran Saxony (anxious to retain its threatened acquisitions) and by Catholic Bavaria (determined to counteract the emperor's aggrandizement) forced Ferdinand to dismiss Wallenstein and so to make himself defenseless at the very moment when Gustavus Adolphus had landed on German soil.

**6. War of the Mantuan Succession (1628-31).**—The death of Vincenzo II Gonzaga, duke of Mantua and Montferrat, on Dec. 26, 1627, led to the first direct clash between the Habsburgs and France, albeit on a secondary theatre of war (*see* GONZAGA; MONTFERRAT). The claims of the legitimate Gonzaga heir, Charles, duc de Nevers, whom France supported, were overridden by Ferdinand II, supreme lord of the imperial fiefs in Italy; and Spain lent military aid to Ferdinand so as to keep a French vassal away from the approaches to Milan. Richelieu, however, was soon stronger. The Huguenot rebels of La Rochelle capitulated to Louis XIII (autumn 1628); Savoyard forces, which attempted to block the French king's way into Piedmont, were defeated at Susa (March 6, 1629); and the Peace of Susa with England (April 14), followed by the submission of the Huguenot rebels in Languedoc to the Peace of Alais (June 28), secured the French rear. The Habsburg forces withdrew from Casale in October 1630; and Richelieu, who in November triumphed over the pro-Spanish faction in France (the so-called Day of Dupes), achieved full success. By the Treaty of Cherasco (June 19, 1631), the French candidate was installed in Mantua. Meanwhile Savoy had ceded the fortress of Pinerolo to France; and Pope Urban VIII, determined opponent of the Habsburgs, annexed Urbino, another vacant imperial fief. The Austro-Spanish monopoly in Italy was broken.

**7. Swedish War (1630-35) and the Peace of Prague.**—The suspension of hostilities between Sweden and Poland freed Gustavus Adolphus to intervene in Germany. After landing at Usedom (July 6, 1630), he quickly occupied the whole duchy of Pomerania and restored Wallenstein's duchy of Mecklenburg to its hereditary dukes. He concluded the Treaty of Bärwalde (Jan. 23, 1631) with France, whereby he was to receive annual subsidies of 1,000,000 livres to enable him to campaign for the restoration of the "liberty" of the German princes "oppressed" by the emperor. In these circumstances an immediate objective for Gustavus was to stop the enforcement of the Edict of Restitution on Magdeburg (*q.v.*), which commanded a strategic crossing point on the Elbe; but his advance into central Germany was impeded by the hardly veiled hostility of the electors George William of Brandenburg and John George I of Saxony. They tried at the Convent or Conference of Leipzig (February 1631) to establish a neutral party between the emperor and Sweden, which proved unacceptable to either. Though Gustavus stormed the Brandenburg fortress of Frankfurt an der Oder (April 13), thereby both securing his left flank against the Poles and intimidating the two electors, the delay led to the fall of Magdeburg to Tilly (May 20). Brandenburg and Saxony now yielded to the Swedish threats, especially as Tilly imprudently invaded Saxony and treated it as enemy country. Alliances with Brandenburg (June 20) and with Saxony (Sept. 11) protected Gustavus' rear and virtually rendered the electorates Swedish satellites. The defeat of Tilly at Breitenfeld (Sept. 17) and the conquest of Prague (Nov. 15) by the Saxons under Hans Georg von Arnim (*q.v.*) opened southern Germany to the Swedes.

The smaller German Protestant princes, such as Bernhard (*q.v.*) of Saxe-Weimar, flocked to Gustavus' standards; by April 1632 Gustavus had advanced as far as Munich, and his armies had reached Lake Constance to the south and Mainz to the west. The archbishopric of Mainz and the Rhenish Palatinate were placed under Swedish administration; the bishoprics of Würzburg and Bamberg were given to Bernhard as a Swedish fief under the name of Duchy of Franconia. The king's war aims gradually widened: his agreements with the German princes became more onerous, and the stipulations which the Treaty of Bärwalde had made for the protection of France's friends and of the Catholic religion were treated lightly. Gustavus did not aim at the imperial crown, but his secret negotiations with Wallenstein show that he thought of placing the Habsburg dominions under the rule of Swedish puppets.

The recall of Wallenstein to the leadership of the Imperial Army completely changed the situation; Gustavus was maneuvered out of southern Germany and shortly afterward was killed in the battle of Lützen (Nov. 16, 1632). While the conduct of Swedish

military operations then fell to Johan Banér and subsequently Lennart Torstensson (*qq.v.*), the direction of policy was undertaken by the chancellor, Axel Oxenstierna (*q.v.*), who by the Treaty of Heilbronn (April 23, 1633) consolidated the Swedish alliance with the German princes, albeit without Brandenburg and Saxony. Wallenstein's victory at Steinau in Silesia (Oct. 11) and Bernhard's capture of Regensburg (Nov. 14) cancelled each other out, and Wallenstein's machinations to make himself the arbiter of affairs caused the emperor to have him murdered (Feb. 25, 1634); but the Swedish defeat at Nördlingen (Sept. 5-6, 1634) led to the dissolution of the League of Heilbronn and to the open defection of most German princes, led by Saxony, from the Swedish cause.

The Peace of Prague (May 30, 1635) reconciled the emperor and nearly all the German opponents of the Edict of Restitution, which it modified by making the year 1627 the criterion of rightful possession of ecclesiastical lands (instead of 1552). Henceforth Sweden played only a subordinate part in the war. The leading role fell to France.

**8. War of Smolensk (1632-34).**—From c. 1628 Gustavus Adolphus and Richelieu had been trying to bring about alliances with Russia, Turkey, Transylvania, the Crimean Tatars, and the Ukrainian Cossacks, who were to engage the emperor and Poland on their eastern frontiers. Concerted action, however, proved difficult to achieve. But Moscow gave Gustavus considerable indirect aid by selling to Sweden, on a cash-and-carry basis at an artificially low price, cereals which the Swedes resold in Amsterdam at considerable profit: between 1628 and 1633 the Swedes bought Russian grain at a cost of 100,000 talers per annum and sold it at 400,000 talers per annum (the latter sum being equal in amount to the direct subsidy received annually from France). Russo-Swedish military cooperation was eventually achieved, largely through the efforts of Sweden's envoy Alexander Leslie (later earl of Leven in the peerage of Scotland): the Russians invaded Poland in autumn 1632 and besieged Smolensk, while Gustavus Adolphus moved eastward and ordered his general Karl Gustav von Wrangel to prepare an offensive from his bases in Prussia.

The great scheme came to nought. The deaths of Gustavus Adolphus and of the Moscow patriarch Philaret (October 1633), who had been the two chief architects of Swedish-Russian cooperation, removed the mutual goodwill as the basis for a real alliance. Turkey moreover was committed in a war with Persia; the Tatars of the Crimea turned against Muscovy instead of Poland; and the revolt of the Ukrainian Cossacks against their Polish overlords was delayed. Finally an insurrection of the peasants in central Russia forced Tsar Michael's government to conclude the Peace of Polyanov with Poland (June 14, 1634).

**9. French and Swedish War (1635-48).**—The near-collapse of the Swedish system in Germany in 1634-35 forced Richelieu to abandon his cautious policy of nonintervention. He concluded offensive and defensive alliances with the United Provinces (Feb. 8, 1635) and with Sweden (Treaty of Compiègne, April 28); sent a French army to the Valtellina (March-April); and declared war on Spain (May 19). He then secured an alliance with Savoy and Parma (League of Rivoli, July 11); mediated the 20-year Truce of Stuhmsdorf between Sweden and Poland (Sept. 12); and took the best of the German generals still serving Sweden, Bernhard of Saxe-Weimar, into French pay (Oct. 27). In 1636 the invasion of northern France from the Spanish Netherlands by Ottavio Piccolomini (*q.v.*), whose capture of Corbie (Aug. 15) threatened to

expose Paris, was outweighed by a series of Swedish victories over Saxon and imperial forces, culminating in Banér's defeat of Melchior von Hatzfeldt at Wittstock (Oct. 4), which reestablished Swedish supremacy in north and central Germany. A careless northward movement of the imperial commander in chief, Matthias Gallas, in 1637, laid southern Germany open to the French; and Bernhard of Saxe-Weimar, having overrun Alsace, in 1638 conducted a brilliant campaign in the course of which he took the key fortresses of Rheinfelden (March 23), Freiburg (April 6), and Breisach (Dec. 17). Before Bernhard's death the incompetence of the French led to Piccolomini's great victory of Thionville (June 7, 1639), which however was to be the last success of the Austro-Spanish armies. The outbreak, in 1640, of revolution both in Catalonia and in Portugal compelled the Spaniards to limit their commitments outside the Iberian Peninsula. The capitulation of the great stronghold of Arras to the French (Aug. 9, 1640) endangered the Spanish position in the Netherlands, and a Spanish counteroffensive into Champagne ended with the French victory at Rocroi (May 19, 1643), won by the young duc d'Enghien (see CONDÉ, LOUIS II DE BOURBON, Prince de).

In Germany the various commanders, French, Swedish, Bavarian, and imperial, waged war almost on each one's own responsibility; no coherent pattern can be found in those campaigns, which were nearly always small-scale raids with limited objectives. The Swedish victory over Saxon and imperial forces at Breitenfeld (Nov. 2, 1642) and the capture of the Little Town quarter of Prague by the Swedes (July 26, 1648) are—besides the Swedish campaign against Denmark—the most notable military events of these years. They were overshadowed by the diplomatic activity which began in 1640 and ended in 1648 with the Peace of Westphalia.

During the French and Swedish War death had removed three great figures from the international scene: the emperor Ferdinand II on Feb. 15, 1637, leaving the succession to his son Ferdinand III (q.v.); Richelieu on Dec. 4, 1642; and Louis XIII of France on May 14, 1643. Richelieu's place was taken by Cardinal Mazarin (q.v.) during the regency for Louis XIV.

**10. Swedish-Danish War (1643–45).**—The precarious situation of the imperial cause after Breitenfeld and the Danish jealousy and fear of Sweden brought about an understanding between Ferdinand III and Christian IV; and Sweden's decision to wage a preventive war against Denmark gave the emperor a respite, since the Swedish Army under Torstensson had to abandon its march on Vienna (September 1643) and to turn northward instead. In a lightning campaign (December 1643–January 1644) Torstensson conquered Schleswig-Holstein and Jutland. When an imperial army under Gallas came to the succour of the Danes, Torstensson at once marched against him, destroyed his army at

Jüterbog (Nov. 23, 1644), and invaded Bohemia, where another imperial army was wiped out at Jankov (March 6, 1645). By the Peace of Brömsebro, signed on Aug. 23, 1645, Denmark ceded Jämtland and Härjedalen on the Norwegian frontier, Halland on the Kattegat, and the Baltic islands of Gotland and Ösel to Sweden.

**11. Peace of Westphalia (1648).**—Treaties signed in the Westphalian towns of Münster and Osnabrück terminated both the Eighty Years' War between Spain and the United Provinces of the Netherlands (Jan. 30, 1648) and the war between France, Sweden, and the German Protestants on the one side and the emperor and the German princes on the other (Oct. 24).

*The Negotiators.*—The Peace of Prague (1635) between the emperor Ferdinand II and the majority of the German princes had proved abortive: it expressed too much the temporary ascendancy of the emperor, took little account of Sweden, and completely disregarded France, which at that very moment openly took up arms against Spain and the emperor. No general peace was possible without the participation of Sweden, France, and Spain, and in 1640 the parties began in earnest to prepare the summoning of a peace congress. The emperor Ferdinand III entered into secret negotiations with Sweden in Hamburg; the Imperial Diet demanded a universal congress instead of bilateral transactions. The renewal of the Franco-Swedish alliance on June 30, 1641, included the stipulation that two congresses be held simultaneously in neighbouring Westphalian towns: in Münster, the Catholic envoys, in Osnabrück the Protestant envoys were to meet.

In 1643–44 Sweden and France sent out the first invitations, and the congress began to take shape. The slow and tortuous negotiations about procedure and substance, protocol and ceremonial, the admission or rejection of envoys and mediators—all these fumbblings which went on right to the actual signing of the treaties—were mostly due not to obstruction but to inexperience. By trial and error the congress had to explore and define the methods of modern international diplomacy. The 150 representatives (about 110 Germans and 40 foreigners) lacked any precedent for their tasks, starting, as it were, from scratch every time a fresh topic turned up. They gradually developed a kind of *esprit de corps* which cut across political and religious frontiers and contributed not a little to the realistic settlement which was satisfactory to all but a few diehards.

Though the plenipotentiaries were bound fairly narrowly by instructions from their governments, a few figures stand out to whom the successful outcome was largely due. The imperial ambassador, Maximilian Graf Trauttmansdorff, outshone the rest; he had been the architect of the Peace of Prague and became the main author of the Peace of Westphalia. He and his chief secretary, Isaac Volmar, were converts to the Roman faith and therefore understood the opposing positions and did their best to check the firebrands in the Catholic camp. France was brilliantly represented by the duc de Longueville (Henry d'Orléans) and his duchesse (Anne Geneviève de Bourbon-Condé), but as members of the princely faction they were suspect to Mazarin. Mazarin also mistrusted France's principal actual negotiator, Claude de Mesmes, comte d'Avaux, whereas the latter's equally skilful but more ruthless colleague, Abel Servien, enjoyed the cardinal's confidence; their mutual antagonism, however, in no way impaired their efficiency as representatives of the French crown. Similar dissensions rent the Swedish mission: Johan Oxenstierna, the chancellor's son, stood for the policy of conquest sponsored by the Swed-

ish nobility, whereas Johan Adler Salvius, a gifted and experienced diplomat of humble birth, sided with the young queen, Christina, in wishing for peace at almost any price. The Spanish ambassadors, the conde de Peñaranda (Gaspar de Bracamonte) and Antonius Brun, succeeded in terminating the war with the Dutch (Jan. 30, 1648) with great sacrifice to Spanish power but without loss to Spanish honour.

The Brunswick counselor, Jacob Lampadius, stands out as the expert in all legal problems, and the Lübeck envoy, David Gloxin, as the champion of the mercantile interest. Johann Rudolf Wettstein, of Basel, was accredited only as a representative of the Swiss Protestant cantons but acted on behalf of the whole Swiss Confederation. Lastly, the two unofficial mediators must be mentioned, the papal nuncio Fabio Chigi (later Pope Alexander VII) and, especially, the Venetian diplomat Alvise Contarini: they employed their good offices for smoothing out factional divisions and keeping alive the mutual interests of the European comity of nations.

**Territorial Settlement.**—The territorial clauses of the peace treaty all favoured France, Sweden, and their allies.

Sweden obtained the largest share: Hither Pomerania (Vorpommern), with Stettin and so control over the Oder estuary; the Mecklenburg port of Wismar; and the archbishopric (but not the city) of Bremen and the bishopric of Verden, with control over the Elbe and Weser estuaries. In addition, there was the "satisfaction" of the Swedish Army, amounting to 5,000,000 talers, guaranteed collectively by the members of the empire.

France incorporated the cities and bishoprics of Metz, Toul, and Verdun in Lorraine (French protectorates since 1552) and added to them the suzerainty over the secular vassals of the three bishops. France also obtained the ill-defined feudal rights exercised by the emperor over various towns, villages, and districts in Alsace (excluding Strasbourg but including the bridgehead of Breisach); and the permanent right to garrison Philippsburg, on the right bank of the Rhine south of Speyer. These gains appeared modest. However, the possession of Breisach and Philippsburg laid all southern Germany open to French arms; and the deliberate vagueness of the clauses relating to the cessions in Lorraine and Alsace later provided the legal or casuistical pretexts for wars of aggression waged by Louis XIV.

The only major setback which France suffered was the conclusion of the separate peace between Spain and the United Provinces. This deprived France of an ally in the rear of the Spanish Netherlands and prolonged the Franco-Spanish War by a decade.

The gains and losses of the German princes were determined by the convenience of the principal powers, France, Sweden, and Austria. These used the claims of their lesser partners as pawns mainly for adjusting differences among themselves at somebody else's expense.

Brandenburg obtained Farther Pomerania (Hinterpommern); the bishoprics of Kammin, Halberstadt, and Minden; the county of Hohnstein; and the reversion of the archbishopric of Magdeburg on the death of the existing administrator, Augustus of Saxony (which occurred in 1680). Bavaria was to keep the Upper

Palatinate and the electoral dignity, but the Rhenish Palatinate was restored to Frederick V's heir, Charles Louis, for whom a new electorate was created. Saxony retained what had been secured at the Peace of Prague, namely Lusatia and Magdeburg, but the latter only for the lifetime of the present administrator. Hesse-Kassel ousted Hesse-Darmstadt from the district of Marburg and incorporated the abbey of Hersfeld and the county of Schaumburg. The Welfs of Brunswick obtained the right to have one of their princes elected as Protestant administrator of Osnabrück in alternation with a Catholic bishop. Mecklenburg was compensated for the loss of Wismar by the bishoprics of Schwerin and Ratzeburg.

Finally, the United Provinces of the Netherlands and the Swiss Confederation were released from their legal obligations toward the empire and so recognized as independent republics.

**Political and Religious Settlement for Germany.**—For Germany, the Peace of Westphalia brought to a conclusion the century-old struggle between the monarchical tendencies of the emperor and the federalistic aspirations of the princes. Ferdinand II had made considerable progress in revitalizing the imperial power: without consulting the electors or princes, he had arrogated to himself the outlawry of Frederick V of the Palatinate and the transfer of the latter's electoral dignity to Maximilian of Bavaria (1623) and the deposition of the dukes of Mecklenburg (1628); on his own authority, he had interpreted, that is, in fact, rescinded, the Peace of Augsburg by the Edict of Restitution (1629), thereby superseding the legislative authority of the Imperial Diet; and by the Peace of Prague (1635) he had transformed all princely troops into contingents of an army under his supreme command and abolished the princes' traditional right to conclude alliances among themselves or with foreign powers.

The Peace of Westphalia completely reversed this trend. It confirmed the full sovereignty of the members of the empire, including their right to form alliances, restricted only by the meaningless proviso "except against the emperor and Reich." It bound the emperor to the decisions of the Imperial Diet in all matters concerning war and peace. The Diet, which during the past 40 years had met only three times (1608, 1613, 1640-41), increased its sphere of competence at the expense of the emperor as well as the electors; the Protestant administrators of the secularized bishoprics were admitted with full voting rights. From 1663 the Diet remained in permanent session at Regensburg.

The peace established equality of rights between Catholics, Lutherans, and Calvinists: the supreme court of the empire was to be staffed by 26 Catholics and 24 Protestants, and Protestants were admitted to the Aulic Council in Vienna. The Edict of Restitution was repealed, and 1624 was declared the "standard year" according to which territories should be deemed to be in Catholic or Protestant possession. Dissidents were allowed private worship, liberty of conscience, and the right of emigration; only in the Habsburg dominions no toleration was granted to non-Catholics. Religious disputes were not to be decided by majority vote of the Imperial Diet but to be solved amicably between the Corpus Evangelicorum (the Protestant states collectively) and the Corpus Catholicorum, organized under the directorate of Saxony and of Mainz respectively.

## 12. Franco-Spanish War

(1648-59).—The conclusion of a separate peace with the United Provinces helped Spain to continue the struggle against France; and Condé's victory over the Spaniards at Lens (Aug. 20, 1648) was offset by the outbreak of the Fronde (q.v.). During the civil wars in France (1649-53), the rebel leaders, including Condé, even made treaties of their own with Spain. Success came to the French from 1655, especially after the outbreak of hostilities between Spain and England and the conclusion of

 THE BATTLE OF NÖRDLINGEN, SEPT. 5-6, 1634, IN WHICH THE SWEDISH ARMIES (ATTACKING FROM THE LEFT) WERE VIRTUALLY DESTROYED; COPPER ENGRAVING BY M. MERIAN FROM "THEATRUM EUROPAEUM," 1643

Anglo-French treaties of friendship (Sept. 5, 1656) and of alliance (March 23 and May 9, 1657). Robert Blake's exploits in the Mediterranean and in the Caribbean (1655-57), followed on land with the Battle of the Dunes (June 14, 1658) and the capture of Dunkerque (June 25) and Gravelines (Aug. 24, 1658), broke Spain's resistance. In the Franco-Spanish Peace of the Pyrenees (Nov. 7, 1659) France obtained Roussillon and northern Cerdagne (thus establishing the frontier along the line of the Pyrenees), Artois, and a number of frontier fortresses in the Netherlands and Luxembourg. Spain had ceded to France the first place among the great powers of Europe.

**13. First Northern War (1655-61).**—The last decade of the 50-year period here surveyed witnessed another conflict in Northern Europe. It arose, however, from the start of the Thirteen Years' War between Russia and Poland (1654-67), which is best considered as belonging to a later historical period, characterized by the decline of Poland and by the rise of Russia and of Brandenburg-Prussia. In so far as it reaffirmed certain tendencies of the earlier period it may be briefly summarized here.

The question of the Ukraine led to war between Russia and Poland in 1654. Charles X (*q.v.*) of Sweden took advantage of this war to attack Poland in July 1655. The elector Frederick William (*q.v.*) of Brandenburg took the Swedish side from 1656 to 1657 but changed to the Polish in 1658. Russia began war against the Swedes in June 1656 but concluded the Truce of Valiesari in December 1658. In 1657 the emperor Ferdinand III's heir Leopold I (*q.v.*) allied Austria with Poland. Frederick III (*q.v.*) of Denmark attacked Sweden in June 1657.

By the Peace of Roskilde (Feb. 26, 1658) Denmark was forced to cede not only Trondheim on the North Sea coast of Norway but also Bohuslän on the Swedish coast at the end of the Skagerrak, Skåne on the eastern side of the Sound, with adjacent Blekinge, and the island of Bornholm to Sweden, thus forfeiting all hope of the "lordship of the Baltic." Denmark, however, subsequently refused to close the Baltic to Western shipping and was attacked by Sweden again in summer 1658. The Dutch, in their own commercial interests, came to Denmark's support, and the Peace of Copenhagen (June 6, 1660) restored Bornholm and also Trondheim to Denmark, but otherwise confirmed the settlement of Roskilde.

The Peace of Oliva (May 3, 1660), between Sweden on the one hand and Poland, Austria, and Brandenburg on the other, assigned Livonia to Sweden and recognized Brandenburg's full sovereignty over ducal Prussia, both these stipulations being made at Poland's expense. The Russo-Swedish Peace of Kardis (July 1, 1661) re-established the terms of the Peace of Stolbova (1617).

France had played an active role in mediating the Baltic settle-

ment. Habsburg Austria had gained nothing from the conflict and was meanwhile confronted by the League of the Rhine (Aug. 14, 1658), organized by Mazarin, whereby France, Sweden, the electoral archbishoprics (Mainz, Cologne, and Trier), Münster, Brunswick-Lüneburg, Palatinate-Neuburg, and Hesse-Kassel guaranteed the Peace of Westphalia against Habsburg revisionism.

#### IV. GERMAN CIVILIZATION

**1. The Population.**—Any estimate of the movement of population of Germany between 1600 and 1650 is hampered by the absence of any census before the 18th century and the vagueness of the territory to which any statistics could be applied. All assertions of a decline of the population during the war by one-third or even more are therefore baseless guesswork. The computation of the population of "Germany" as a whole at the beginning or the end of the war would differ by about one-quarter or more according to the inclusion or exclusion (either of which can be defended on historical grounds) of certain territories, such as the Netherlands, Switzerland, Schleswig-Holstein, Brandenburg's Polish fief of Prussia, Spain's French-speaking possessions in Luxembourg and in Franche-Comté, French-speaking Lorraine, the Slav-speaking parts of Austria's possessions (Bohemia, Moravia, Carniola, Styria), and the Italian-speaking Trentino.

Such statistical surveys as were occasionally made for a small district were nearly always prompted by the wish to support some special pleading: to obtain a grant-in-aid, to reduce a tax assessment, to avoid military service or statute labour. The main sources on which historians have drawn are the reports of chroniclers and, rarely, parish registers of death—to the virtual exclusion of registers of marriages and births. In view of the huge birth-rate this neglect amounts to 30-50%; *i.e.*, to that one-third or one-half by which the population is said to have been reduced.

Death on the battlefield can be left out of count because the armies of the time, and consequently their losses, were very small. The Catholic League had an effective strength of about 15,000 men; Gustavus Adolphus landed in Germany with 15,000 men; Bernhard of Saxe-Weimar received French pay for 18,000 men; the strongest French army employed in Germany (in 1645) numbered 12,000; the first Imperial Army raised by Wallenstein in 1625 consisted of 15,000 foot and 6,000 horse.

The most serious losses were caused by epidemics, especially typhoid, the plague, and venereal diseases, spread by soldiers and refugees and intensified by lack of hygiene and incompetence of doctors. However, a few chance survivals of accurate lists of victims make it certain that during the worst outbreaks of the "pest" (the generic name applied to every epidemic) the mortality reached only 12%, and that in thickly populated towns. The

average annual mortality rate seems to have been around 6 or 7%.

The most plausible explanation of the depletion of certain parts of Germany is to be found in an extensive internal migration, chiefly from the agrarian village to the industrial town and from the economically declining to the economically prosperous town (as for instance from Cologne to Frankfurt). But there was also a considerable fluctuation of refugees and evacuees from open country to the safety of the walled town: Kiel and Lübeck served as refuges for the gentry of Holstein. A typical example of this temporary dislocation of the population can be seen in five Thuringian rural districts for which accurate statistics have been computed: numbers declined during the years 1631-49 between 66 and 87% and increased in the decade 1649-59 by between 78 and 125%. The net result of this redistribution of population was an all-around though small increase of the total population such as is characteristic of every predominantly agricultural society. Bearing in mind the elasticity of the term "Germany," one can assume a population of 15,000,000-17,000,000 in 1600 and one of 16,000,000-18,000,000 in 1650, as may be inferred from the figure (fairly well attested) of 17,000,000-20,000,000 for the Empire in 1700.

**2. Economic Life.**—The years round 1620 saw German economic life at its lowest point. For centuries its strength, like that of Italy, had lain in the flourishing towns, where industry, banking, and trade (import and export) were concentrated. From the middle of the 16th century the heyday of their prosperity was over. Politically, the free cities succumbed to the growing power of the territorial princes; only a few—Lübeck, Hamburg, Bremen, Danzig, Nürnberg, Augsburg, Frankfurt—maintained more than an outward semblance of independence.

Economically the Hanse towns of northern Germany (see HANSEATIC LEAGUE) were severely hit by the Muscovites' destruction of Novgorod (1570), by the Spaniards' sack of Antwerp (1585), and by Queen Elizabeth I's closing of the London Steel-yard (1598); and the separation of the United Provinces from Spain gave to the Hanse's Dutch rivals a free hand to break its monopoly in the Baltic. The south German cities, whose bankers were deeply involved in the financial transactions of both Austrian and Spanish Habsburgs, were largely ruined by the repeated bankruptcies of the Spanish crown (1557, 1575, 1596, 1607); the insolvency of the Augsburg firm of Welser in 1614 was only the most spectacular debacle of many.

The collapse of the old order was made evident in the big inflation of the years 1619-23, which brought utter ruin to the classes dependent on savings, annuities, or fixed incomes but provided colossal gains to versatile financiers and industrialists as well as to unscrupulous speculators and profiteers. The emperor Ferdinand II, who lent his active support to a combine of ruthless racketeers, and the dukes of Brunswick-Wolfenbüttel were conspicuous among the "legal" counterfeiters. When the currency was stabilized again in 1624, a thoroughgoing transfer of capital had occurred: none of the old-established and sometimes decadent firms survived, and their place was taken by pushing upstarts. This changeover of family and business fortunes continued: the proscription of Wallenstein and his adherents in 1634 permitted the Viennese courtiers and generals to acquire for a song the richest Bohemian and Silesian estates.

In fact, the inflation of 1619-23 was the turning point. The outward sign of economic recovery was the establishment of the big clearing banks of Hamburg (1619) and Nürnberg (1621); the Hamburg "Mark Banko" was for two centuries the most stable international currency unit till the pound sterling superseded it.

In German agriculture, too, a regrouping of ownership and profits rather than a general decline is to be noted. The steady rise of corn prices from the mid-16th century made large-scale farming and bulk-selling more profitable; and from the end of the 16th century the feudal owners of big estates practised wholesale evictions of peasants and forced acquisition of peasant lands, thereby depopulating the countryside and obliterating hundreds of villages. As far as can be ascertained, those villages which were wholly or partly burned down by the soldiery in the course of the war were all rebuilt and even enlarged before the end of it;

and the same is true of Magdeburg, the only town of any size to be severely damaged by enemy action. The wars themselves proved a source of gain to the big landowners, who supplied victuals, grain, and livestock to the contending armies, whereas the small farmer could not compete with the lord of the manor and moreover endured greater hardship from marauding troops than did the townsman. Especially in those areas which suffered least from the military invasions—Prussia, Pomerania, Brandenburg, and Mecklenburg—the formerly free farmers were reduced to virtual or legal serfdom.

Apart from the destructive effect of every war, it must be borne in mind that all the campaigns of the first half of the 17th century were of short duration and almost invariably centred round the same focal points which, by their geographical position, have been fought over again and again from time immemorial: the Alpine passes, the Rhine crossings, the bridgeheads of Regensburg on the Danube and Magdeburg on the Elbe, the plains of Leipzig and Brabant. However, the resilience of the people of these districts has always been equal to their plight—as can be seen, for instance, at Leipzig. That city went bankrupt in 1625, was bombarded and stormed in 1631, 1632, 1633, 1637, and 1642, witnessed the major battles of Breitenfeld (1631 and 1642) and Lützen (1632) before its very gates, and was under Swedish occupation from 1642 to 1650; but in these years the annual Leipzig Fair established itself as the centre of European trade, and in 1640 the town council reported regular trade relations with Italy, Poland, England, Brabant, Scandinavia, the Ukraine, and the intermediate countries. Parts of Germany were affected by hostilities for a few weeks, others not at all. Most towns never saw an enemy within their walls.

Of all the wild exaggerations concerning the moral degeneration of the German people caused by the Thirty Years' War that of cannibalism due to famine and starvation has a morbid appeal which few writers have been able to withstand. The refutation of these stories is the more difficult as the original accusations were vague, the source material is buried in the files of rural magistrates' courts, and critical investigations are scattered in obscure journals. It seems that one case of cannibalism can be taken as established: it occurred among the starving garrison of Breisach during the long siege in 1638. A second case proven in court is that of a Silesian bandit tried in 1654: having killed a pregnant woman, he ate her unborn child's heart in order, as he confessed, to make himself "stronger and fiercer"—a clear example of a form of superstitious magic known to anthropologists. Every other story of cannibalism that has been investigated can be shown to be the adaptation of some classical or medieval fable, if not simply a journalistic stunt. Thus, a contributor to a popular serial in 1639 startled his readers with the rhetorical question: "Has Germany become America? Cannibals now openly walk about . . ." The vicar of a Palatine village, asking his co-religionists abroad for donations, asserted that "food is so scarce that the dead are no longer safe in their graves." This unsubstantiated hint proved so effective that henceforth no appeal to charity dispensed with references to body-snatching and cannibalism.

**3. Literature and the Arts.**—The great impetus of the Renaissance and the intellectual fervour of the Reformation had exhausted themselves by 1570, just when Italy, France, England, Spain, and the Netherlands entered upon a fresh period of cultural grandeur. From the general European point of view, Germany was overshadowed and virtually ceased to count as an independent contributor in the cultural field. The picture of the years 1600-50, however, is different when studied from the narrower German angle. From the start of the 17th century onward German scholars, scientists, musicians, writers, and poets were coming again to the fore and producing works which were to have lasting influence upon German culture. The legend of the cultural exhaustion and desolation of Germany during and after the Thirty Years' War is solely due to the aesthetic standards of 19th-century historians, who despised the Baroque style and so could not appreciate the work of Baroque artists and writers. Moreover, the huge spate of German translations chiefly of Italian, Spanish, and French scholars and scientists, prose writers, and poets tends to be overlooked.

Italian influence was especially prominent in the German theatre of the time, in which decor, stage effects, and music were combined to produce operatic showpieces: the plays (in Latin) of the Jesuit Jakob Bidermann (1578–1639) and the Passion play of Oberammergau (q.v.; first performed in 1634) are spectacular examples. The composer Heinrich Schütz (1585–1672) helped to establish the fashion for Italian music in Germany with his madrigals, symphonies, and oratorios as well as the first German opera (*Dafne*, 1627) and the first German ballet (*Orpheus und Eurydice*, 1638).

German language and literature had enthusiastic though somewhat pedantic nurseries in the literary societies modeled on the Florentine Accademia della Crusca, of which the Weimar *Fruchtbringende Gesellschaft* (1617) was the oldest and most influential, followed by the Hamburg *Teutschgesinnte Genossenschaft* (1643), the Nürnberg *Pegnitzorden* (1644), and others. Aiming at a purification of the German language, the encouragement of writers, and an improvement of manners and morals, they listed among their members numerous leaders of society and every literary figure of note. Martin Opitz (q.v.), with his *Buch von der deutschen Poeterey* (1624), and Justus Georg Schottel (1612–76) with his *Teutsche Sprachkunst* (1641) standardized the theory of New High German poetics and grammar for 150 years. Opitz's own poetry is unoriginal and largely modeled on the French poets of the Pléiade; but as he tried his hand in every type of fashionable literature and was a prolific translator, his influence was considerable throughout 17th-century Germany. The mystical poems of Friedrich Spee (1591–1635), the epigrams of Friedrich von Logau (1604–55), the Latin odes of Jakob Balde (1604–68), the satirical novels of J. M. Moscherosch (1601–69), the hymns of Simon Dach (1605–59) and of Paul Gerhardt (1607–76), the occasional and patriotic poems of Georg Rudolf Weckherlin (1584–1653), the plays of Andreas Gryphius (q.v.; 1616–64), and the novel *Die Adriatische Rosemund* of Philipp von Zesen (1619–89)—these highlights of the German literature of the war years are still read. Their testimony to a flourishing literary life is further supported by the expansion of the two leading German printers and publishers, Endter in Nürnberg and Stern in Lüneburg, whose books, pamphlets, hymnals, calendars, etc. were bought by the middle and lower classes in, at least, every Protestant region of the empire.

The outstanding figure in German science is the astronomer Johannes Kepler (q.v.), who discovered the laws of the planets while serving successively the emperor Rudolf II, the Estates of Upper Austria, and Wallenstein. Otto von Guericke, who as councillor and burgomaster of Magdeburg supervised the reconstruction of the city after 1631, was the inventor of the air pump and manometer. The Naturwissenschaftliche Gesellschaft, founded in Rostock in 1622, was the first learned society to devote itself primarily to the advancement of science. The English physician William Harvey chose a Frankfurt publisher to bring out his discovery of the circulation of the blood (1628).

In art and architecture, the influence of Palladio and Bernini was strong enough to italianize all building in the south of Germany, whereas the northwest fell under Dutch influence. Maximilian of Bavaria patronized the Dutchman Peter Candid, a pupil of Giorgio Vasari, as painter and builder for his palaces in Munich and Schleissheim. All the palaces, cathedrals, and churches built in the 17th century by the Habsburg rulers and their courtiers in Vienna, Salzburg, Graz, Innsbruck, and Prague were the work of Italian designers, as were Wallenstein's palaces in Prague, Jičín, and Sagan. On the whole, however, there was little incentive for new building, since the great buildings of the prosperous first three-quarters of the 16th century still served the need of the majority of their owners. Most private houses of the less well-to-do are artistically insignificant and have therefore failed to gain entry in the histories of architecture. A lively interest in architecture, however, is attested by the success of several textbooks for the instruction of builders and their clients, such as that by Rüdiger Kossmann of Cologne (first published in 1630 and reedited in 1644 and 1653) and three by Josef Furtenbach of Ulm (1628, 1640, and 1641).

## V. CONCLUSION

The European struggle against the predominance of Spain is the main topic of all the hot and cold wars, diplomatic moves and alignments, religious and constitutional tensions which fill the history of the first half of the 17th century. The Thirty Years' War, so called, is merely a segment of this general upheaval. The result, in the peace treaties of Westphalia and of the Pyrenees, can be summed up as follows.

In the field of international as well as of German politics, the sovereignty and independence of the individual state was established as the principle on which henceforth the European comity of nations and, in the narrower German context, the framework of the Holy Roman Empire were to be based. For Germany this structure survived, with modifications (notably in the Napoleonic period), until the foundation of the German Empire under Prussian hegemony in 1871; and for Western Europe the principle was maintained into the second half of the 20th century. The medieval conception of the theoretical unity of the *respublica Christiana* with the Roman emperor and the Roman pope as its temporal and spiritual heads was formally abandoned in favour of a community of sovereign, independent states, of equal status, regardless of form of government or confession of faith, though united by a common adherence to certain fundamental principles of law and order. This was a first, tentative step toward a European community, in which, however, Great Britain and Russia were not included.

(1943); for a Marxist interpretation see J. Polišenský, "The Thirty Years' War," in *Past and Present*, 6 (1954). For the Peace of Westphalia see E. Hövel (ed.), *Pax optima rerum* (1948); M. Braubach, *Der Westfälische Friede* (1948); F. Dickmann, *Der Westfälische Frieden* (1959). (S. H. S.)

**THISTED**, an amt (county) in northwest Jutland (Jylland), Denmark, comprises the peninsular province of Thy, with its smooth dune coast, and the island of Mors (area 140 sq.mi. [363 sq.km.], pop. [1960] 26,766) in the great inland broad of Limfjorden. Total county area is 685 sq.mi. (1,774 sq.km.). Pop. (1960) 84,955. The soils of Mors and the eastern part of Thy range from sandy loams to heavier clay loams of moderate fertility supporting mixed farming. Coniferous plantations clothe the dunes. Nykøbing (pop. [1960] 9,326) is the principal town of Mors with an iron foundry and oyster canneries. Thisted town (pop. [1960] 8,768), the urban centre for Thy province, makes machinery, textiles, and beer. (Ha. T.)

**THISTLE**, a name of vague application, given to almost any herbaceous plant that has spines. More strictly, it is applied to certain herbs possessing very spiny leaves, and similar bracts surrounding a head of rose, purplish, or yellowish, tubular, five-parted flowers seated on a pitted and hairy receptacle, belonging to the

Compositae family. The fruit is surmounted by a tuft of hairs. The species, chiefly natives of Europe, western Asia, and North America, are numerous, and some are of great beauty.

Plumed species constitute the plumbed thistles, some of the most pernicious weeds, especially *C. arvense*, the Canada thistle. This deep-rooted, erect perennial, native to Europe, is now extensively naturalized throughout North America in fields and waste grounds. It may grow to be six feet high. The grooved stems, somewhat branched above, bear deeply cut, exceedingly prickly leaves and numerous showy, fragrant purplish flower heads,

JOHN H. GERARD

FIELD THISTLE (*CIRSIIUM DISCOLOR*)

about one inch across; staminate (male) and pistillate (female) flowers are sometimes borne on separate plants. In Europe *C. arvense* is called the creeping thistle because of its whitish lateral roots that give rise to daughter shoots. Because of its white woolly leaves and rose-purple flowers *C. occidentale*, from California and southern Oregon, is sometimes planted for bolt effect in gardens.

The plumeless thistles, probably native to the Balkans, belong to the genus *Carduus*. In these species, the seeds have a bristly projection instead of a feathery plumed one, as in *Cirsium*.

The blessed thistle is *Cnicus benedictus*; lady's thistle, the leaves of which are spotted with white, is *Silybum marianum*. The common bull thistle, *Cirsium lanceolatum*, seems to be the most suitable prototype for the Scots thistle, though that honour is also conferred on, among other species, *Onopordon acanthium*, the cotton thistle, remarkable for its covering of white down, a doubtful native of Great Britain.

Among other thistles the following, all introduced from Eurasia, are well-known noxious weeds of farmlands in the northern United States and Canada. The blue thistle (*Echium vulgare*) is a biennial member of the borage family. The Russian thistle (*Salsola kali*), so common on the Great Plains of western North America, is an introduced annual tumbleweed belonging to the pigweed family. The perennial sow thistle (*Sonchus arvensis*), a milky-juiced member of the family Compositae, because of its freely creeping root system, is one of the most persistent weeds of arable lands.

The great objection to thistles from an agricultural point of view resides in the freedom with which their seeds are spread and in the vigour of their underground growth, which makes their eradication difficult. Short rotation of crops, clipping of pastures, intense cultivation of field crops, and rigorous cutting of thistles along roadsides and in waste grounds before the seeds mature are only partly effective. The best control is spraying young foliage with 2,4-D or other weed killer in full sunlight with an air temperature of 70° or higher. (W. C. M.; N. Tr.)

**THISTLEWOOD, ARTHUR** (1774–1820), English revolutionary, principal instigator in 1820 of the Cato Street Conspiracy, a plot to murder the British cabinet, was born at Tupholme, Lincolnshire, the son of a farmer. After visiting the United States and France he became a soldier. He developed republican sympathies and joined the Spencean Society, a revolutionary organization, in London. In December 1816 he helped to arrange a meeting in Spa Fields, London, which was to be followed by the seizure of the Tower of London and the Bank of England. The proposed rising failed, but the Habeas Corpus Act was suspended (February 1817), and Thistlewood and a fellow conspirator James Watson were tried. Both were acquitted, but Thistlewood was later sentenced (May 1818) to a year's imprisonment for challenging the home secretary, Viscount Sidmouth, to a duel. After his release, at a time of great distress and unrest, he prepared a plot to assassinate the members of the cabinet and to set up a provisional government. On Feb. 23, 1820, the cabinet ministers had arranged to dine at the earl of Harrowby's house in Grosvenor Square. The authorities had been informed of the plot and on the evening of the 23rd, as Thistlewood with some associates was preparing to leave a room in Cato Street, off the Edgware Road, for Grosvenor square, officers appeared and arrested some of them. Thistlewood escaped, but was seized the next day. There were minor disturbances in London, but they were quickly quelled. Tried for high treason, Thistlewood and four others were sentenced to death and were hanged outside Newgate prison on May 1, 1820. (A. BRL.)

**THÖKÖLY, IMRE** (1657–1705), leader of the Hungarian Protestants in their struggle against Austrian Habsburg rule and, for a few years, titular prince of Transylvania. He was born on Sept. 25, 1657, into a Protestant noble family, at Késmárk (Kežmarok in Slovakia), in that part of the Hungarian kingdom which the Turks had not conquered from the Habsburgs; but in 1670, when his father was executed for his role in the Hungarian magnates' conspiracy against the Holy Roman emperor Leopold I, he took refuge in Transylvania (q.v.), where his kinsman, Michael Teleki, was chief minister to Prince Michael Apafi I. The emperor Leopold's regime, however, launched such a persecution against

the Protestant malcontents in Habsburg Hungary that in 1678 the refugees on the Transylvanian border began war on behalf of their oppressed compatriots. Encouraged by promises of support from King Louis XIV of France (at war against Leopold till 1679) and backed by Apafi and by the Turkish pasha of Nagyvárad (Oradea), they elected Thököly as their commander in chief in 1680. He soon occupied much of Upper Hungary. Leopold was forced to conclude the Treaty of Sopron (1681), by which the liberties of the kingdom were restored.

In 1682 Thököly augmented his prestige by marriage to Ilona Zrinyi, widow of Ferenc Rákóczy I (q.v.). He then renewed the war against Leopold. His forces overran the whole of Upper Hungary (of which he took the title of prince) and advanced to the Vág (Vah) River; but his Turkish allies were defeated in their historic attempt to take Vienna by siege (1683). As the Austrians gradually reconquered the Hungarian lands, Thököly's fortunes declined, and he became more and more dependent on the Turks, who in 1690 appointed him prince of Transylvania. He won a victory over the emperor's forces at Zernest (Zărnești) in 1690; but after the Austro-Turkish Peace of Carlowitz (1699), whereby Leopold recovered Hungary and Transylvania, Thököly had to go into exile in Turkey. He settled at Izmit (Nicomedia), where he died on Sept. 13, 1705. His remains were transferred to Késmárk in 1906. (T. K.)

**THOMAS, SAINT**, one of the 12 apostles. The name means "twin" in Aramaic, as is recognized in John 11:16 ("called Didymus" or "twin" in Greek). He is called Judas Thomas (i.e., Judas the Twin) by the Syrians and in the *Acts of Thomas* (see below); and in some Syriac manuscripts of the Gospel of John his name, Thomas, or Judas Thomas, is given in John 14:22 rather than "Judas (not Iscariot)," suggesting an identification with Judas "of James" (see JUDAS, SAINT). The apostle's character is most clearly outlined in the Gospel of John. "Doubting Thomas" is derived from John 20:24–28, where, by his confession of faith in verse 28, Thomas becomes the first person explicitly to acknowledge Christ's divinity.

Eusebius, in his *Church History* (early 4th century), says that Thomas was the evangelist of "Parthia," perhaps because Edessa, where some of the apostle's bones were said to be preserved, is sometimes called Edessa of the Parthians. His relics are now supposed to be at Ortona, in the Abruzzi, in Italy, where, according to tradition, they were taken from Edessa by way of the island of Chios. His feast day is July 3 in the Syrian Church, Dec. 21 elsewhere. (See also APOSTLE.)

**Acts of Thomas.—The Story.**—This work (*Acta Thomae*) is one of several apocryphal Acts of apostles (see APOCRYPHA, NEW TESTAMENT). Its basic narrative—which is interspersed with hymns and prayers—is a highly coloured tale describing the selection of Thomas to evangelize India, his journey to the court of King Gundaphorus (the historical Gondophares; q.v.), his preaching and conversions, and his eventual martyrdom and burial on a mountain, from which his bones were later removed and taken to the West.

As a tale, the *Acts of Thomas* is remarkable for the religious emotion that pervades it and for its careful delineation of character, but above all for the hymn chanted by the apostle when in prison. This, commonly known as the "Hymn of the Pearl," is a metrical poem in Syriac describing, under the form of the journey of a prince from his Eastern home to Egypt, the descent of the soul to earth and its return to its heavenly home. It may be an independent composition, of Gnostic origin, inserted into the *Acts*, but for this there is no conclusive evidence.

**Association of Thomas with India.**—"Christians of St. Thomas" is a name often applied to the ancient Christian churches of southern India. It is known that there were Christians of Persian (East Syrian) origin, and doubtless of Nestorian creed, in Ceylon, in Malabar, and at Caliana (north of Bombay) before 550. (See further MALABAR CHRISTIANS.) These ancient Christian communities would be naturally regarded as a surviving branch of the extensive Nestorian missions (see NESTORIANS: Origins and Early History). Many of the Christians in India, however, regard St. Thomas as their founder and appeal to tradition and to the *Acts of*

Thomas in support. They claim that the *Acts* are historical and that they refer in part to the apostle's activity in southern India. Their tradition asserts that he founded the Christian churches in Malabar and then crossed to Mylapur, now a suburb of Madras, where the shrine of his martyrdom, built or rebuilt by the Portuguese in the 16th century, still stands on St. Thomas Mount.

There are objections to the Indian Christians' view, such as the absence of compellingly clear allusions to specifically southern usages in the *Acts*. As to the meeting of St. Thomas and King Gondophares, while a rigorously scientific proof is impossible, yet the substantial agreement of the *Acts* (the sole literary document which mentions this king) with all that is known from other sources is best explained on the supposition that the *Acts* contain a kernel of historical truth. As to the southern journey and the martyrdom in Mylapur, the agreement of the south Indian tradition with that of the Church of Edessa lends a degree of probability to the claim that St. Thomas preached in southern India, suffered martyrdom there, and was there first buried. Historically speaking, however, the evidence remains inconclusive.

**Literary History.**—The *Acts of Thomas* was originally composed in Syriac, and indeed it represents one of the oldest and most idiomatic monuments of Syriac literature. In the 4th century it was translated into Greek and thence into Latin, almost certainly as Manichaean propaganda. The Manichaean taint was soon recognized (e.g., by Augustine), and in its original form the work was branded as heretical. The view taken was that the framework, recounting the journeyings of the apostle, was historical, while the speeches and sermons contained the heresy. In consequence, most manuscripts, both Greek and Latin, contain very little of the speeches while retaining the framework. The original form is to be found only in some very ancient Syriac fragments.

**Early Christianity.**—The *Acts of Thomas* is a leading authority for the earliest Christianity in the countries east of the Euphrates. According to this document, it was ascetic, marriage being discountenanced and all preoccupation with the things of this world discouraged. Eucharistic prayers are given, but according to the best manuscript sources only bread and water were used. The Lord's Prayer is quoted in full. The name of the apostle is given as Judas Thomas, and it is expressly stated that he was the twin of Jesus Christ. (N. J. T.; X.)

**Apocryphal Gospel of Thomas.**—Among the Coptic Gnostic papyri found in 1945 near Naj' Hammadi in Upper Egypt was a collection of about 114 sayings headed "These are the secret sayings which Jesus the Living spoke and which Didymus Judas Thomas wrote; and he said, He who will find the interpretation of these words will not taste death." The title of the collection is "Gospel According to Thomas." H. C. Puech observed that some of the sayings had already been found in three Greek papyrus fragments from Oxyrhynchus (3rd and 4th centuries). Others occur in "unwritten sayings" recorded by the Church Fathers or by Gnostic writers; some are found in fragments of the apocryphal gospels "According to the Hebrews" and "According to the Egyptians" (see *APOCRYPHA, NEW TESTAMENT*). Many of the sayings, especially parables, closely resemble sayings recorded in the Synoptic Gospels (there are also parallels to John).

The *Gospel of Thomas* was used by 2nd- or 3rd-century Gnostic groups, by Syrian Christians of dubious orthodoxy, and by the Manichees and their successors. It is echoed in the *Acts of Thomas*, though Origen, Eusebius, and later church writers explicitly rejected it. As a whole, it reflects a dualism expressed in hostility toward the world, the flesh, and Judaism; it rejects prayer, fasting, almsgiving, the Old Testament, and family ties in favour of seeking the Kingdom within (identified with self-knowledge) and a mystical unity transcending anything "worldly." The author's basic views are thus fairly close to those of the Naassenes, a Gnostic group described by Hippolytus of Rome (*Refutation* v, 7-8).

The basic question raised by "Thomas" is whether the synoptic-type sayings are derived from an oral tradition, perhaps prior in origin to the Synoptic Gospels, or from these Gospels themselves. Various answers are given by various scholars; the question cannot be regarded as definitely solved, though it would appear that in

most instances the motives of "Thomas" account for changes he may have made. Certainly he intended his work to look as if it came from oral tradition. (R. McQ. G.)

**THOMAS** (d. 1100), archbishop of York who steadfastly repudiated the primacy of Canterbury, known from his birthplace as Thomas of Bayeux, was the son of a priest of good family named Osbert. Thomas was a protégé of the powerful Odo, bishop of Bayeux, who paid for him to study in France, Germany, and Spain, and made him treasurer of Bayeux. He went with Odo to England and became a chaplain of William I the Conqueror. When in 1070 Thomas was appointed archbishop of York, he faced the task of rebuilding and refounding the cathedral and restoring religious life in the northern province after the Conqueror's ruthless devastation. This he largely carried out. He made a profession of obedience to Archbishop Lanfranc personally, not to the see of Canterbury, but in 1072 the Council of Windsor decreed that York was subordinate to Canterbury. Despite this, Thomas protested in 1092 that the new cathedral at Lincoln belonged to his province, and in 1093 agreed to consecrate Anselm only as archbishop and metropolitan of Canterbury, not as "primate of all England." On the death of William II in August 1100, Thomas arrived too late to crown his successor Henry I (Anselm was in exile). He returned to York, where he died on Nov. 18, 1100. His chief claim to fame is his foundation of the cathedral constitution of York, one of the greatest of the English secular cathedrals in the Middle Ages. (G. W. S. B.)

**THOMAS THE RHYMER** (OF ERCELDOUNE) (fl. c. 1250-1290), Scottish poet, whose name has been associated with many prophetic sayings. Probably an owner of property in Ercehdoune (now Earlstoun; q.v.), a village in Berwick County, Scotland, Thomas was presumably dead when his son, as "heir of Thomas the Rhymer," gave this property to Soltre (Soutra) Hospital in November 1294. It seems very likely that he was the author of the metrical romance *Sir Tristrem*, which survives in a manuscript of c. 1330 (first printed in 1804 by Walter Scott). This is a version of the widely diffused Tristan legend; it is ascribed to him by the contemporary English chronicler Robert Mannyng of Brunne (fl. 1283-1338), and opens: "I was at Erchehdoune/With Thomas spak I ther/Ther herd I rede in rounde/Who Tristrem gat and bare."

His fame as a poet was outweighed by his fame as a prophet, which was already well established in the mid-14th century. An early 14th-century manuscript in a southern dialect gives, for example, his prophecy to the countess of Dunbar as to when the Scottish War of Independence will end. He figures in John Barbour's *Bruce* (prophesying that Bruce would be king), in Walter Bower's *Scotichronicon* (foretelling the death of Alexander III in 1286), and in Blind Harry's *Schir William Wallace* (as "Thomas Rimour"). His prophecies first appear in literary form in the early 15th-century *Romance of Thomas of Ercehdoune* (edited in 1875 by J. A. H. Murray). By the mid-15th century Thomas' fame was widespread in England, as well as in Scotland, and prophecies much current in this disturbed period were often ascribed to him. This habit accounts for the 1603 printed edition which attributes to him prophecies of various dates between c. 1430 and c. 1550. As late as the Jacobite revolts of the 18th century these and other prophecies were still consulted. He is now probably best known through the ballad *Thomas the Rhymer*, which Walter Scott included in his *Minstrelsy of the Scottish Border*

(volume ii, 1802), and in popular lore he is usually coupled with Merlin (*q.v.*) and other English seers. The 19th-century Russian poet Mikhail Lermontov (*q.v.*) claimed Thomas as an ancestor.

**BIBLIOGRAPHY.**—*Texts*: Thomas the Rhymer, in W. Scott, *Minstrelsy of the Scottish Border*, vol. ii (1802); J. A. H. Murray, *The Romance and Prophecies of Thomas of Erceldoune Printed from Five Manuscripts* (1875); A. Brandl, *Thomas of Erceldoune* (1880). See also J. M. Burnham, "A Study of Thomas of Erceldoune," in *Publications of the Modern Language Association of America*, vol. xxiii (1908); J. Geddie, *Thomas the Rymour and His Rhymes* (1920); H. M. Fladstick, *Tom der Reimer* (1934). (A. A. M. D.)

**THOMAS (MAGISTER)** (fl. c. 1300 A.D.), known also by his monastic name THEODULUS MONACHUS, Byzantine scholar, belonging to the literary circles in Constantinople under the emperor Andronicus II (1282–1328), whose speeches and letters afford information on contemporary events. His main work, the *Ecloga* (*Ekloge onomaton kai rhematon Attikon*), is a selection of Attic words and phrases, compiled as a help to Greek composition, from the works of Phrynichus, Ammonius, Herodian, and Moeris. He also wrote scholia on Aeschylus, Sophocles, Euripides (with life), and Aristophanes; the scholia on Pindar, attributed to him in two manuscripts, are now assigned to Demetrius Triclinius.

**BIBLIOGRAPHY.**—*Ecloga*, ed. by F. Ritschl (1832), C. Jacobitz (1833), C. D. Beck (1836). Letters and speeches in J. P. Migne, *Patrologia Graeca*, vol. 145 (1865); critical ed. of five further speeches by F. W. Lenz (1963). See also K. Krumbacher, *Geschichte der byzantinischen Literatur*, 2nd ed., pp. 548–550 (1897); A. Turyn, *Studies in the Manuscript Tradition of the Tragedies of Sophocles* (1952), *The Byzantine Manuscript Tradition of the Tragedies of Euripides* (1957); G. Zuntz, *An Inquiry into the Transmission of the Plays of Euripides* (1965). (J. M. Hy.)

**THOMAS, ALBERT** (1878–1932), French statesman and historian, was one of the leaders of the moderate wing of the Socialist Party and in 1919 became the first director of the International Labour Office. He was born at Champigny-sur-Marne, near Paris, on June 16, 1878. He graduated from the École Normale Supérieure and won scholarships that enabled him to travel to Russia, the eastern Mediterranean, and Germany. He early showed interest in history and in the problems of the working class throughout the world. His passionate concern with the latter led him to seek in history for precedents and causes of socialism, syndicalism, and the cooperative movement. His most important scholarly work was *Le Syndicalisme allemand* (1903), in which his Socialist faith was propounded for the first time.

In 1904, when Jean Jaurès launched *L'Humanité*, a Socialist newspaper, he appointed Thomas as assistant editor. Thomas played an important part as one of the leaders of the moderate groups within the CGT (Confédération Générale du Travail). In 1910 he was elected by his native suburb to the Chamber of Deputies.

Thomas's talent for organization was revealed in World War I when he was entrusted with the organization of the railways in September 1914. He became undersecretary of state for munitions in May 1915 and was appointed minister of munitions in December 1916, retaining that post until September 1917. After the fall of the Russian imperial government, Thomas was sent to Petrograd in April 1917. He worked with the Kerenski government and supervised the production of munitions in an attempt to maintain cooperation between the new republic and the Entente.

Meanwhile in France the struggle between the majority section of the French Socialist Party, which supported the war, and the minority section, which was pacifist, culminated in the Stockholm Conference in June 1917. Thomas was a leader of the majority section and was also a strong advocate of the independence of Czechoslovakia and Poland and of the creation of a Greater Serbia and Greater Rumania. Because this policy was opposed by many Socialists, Thomas decided not to stand again in his Paris suburb, but he was returned as a Socialist in the Tarn département in November 1919.

Soon after the election, Thomas was appointed director of the International Labour Organization (League of Nations). He continued until his death to work with prodigious energy for the organization of the ILO, for the extension of its influence, and for the elaboration of an international labour law. He prepared en-

cyclopaedic annual reports, traveled extensively, and earned for himself the title of "labour diplomatist" by securing national ratifications of conventions adopted by the International Labour Conference. The claims of his work in Geneva had led him in 1921 to resign his seat in the Chamber of Deputies. He died in Paris on May 7, 1932. See further INTERNATIONAL LABOUR ORGANIZATION.

**BIBLIOGRAPHY.**—J. T. Shotwell (ed.), *Origins of the International Labor Organization*, 2nd ed. (1934); E. J. Phelan, *Yes and Albert Thomas* (1936); B. W. Schaper, *Albert Thomas* (1953).

**THOMAS, (CHARLES LOUIS) AMBROISE** (1811–1896), French composer of operas, including the ever popular *Mignon*, was born at Metz on Aug. 5, 1811. He was a pupil at the Paris Conservatoire of J. F. Lesueur and in 1832 won the Prix de Rome with his cantata *Hermann et Ketty*. The operas and ballets that he wrote between 1837 and 1844 achieved little success and Thomas temporarily withdrew from the opera world. His reputation became established, however, with *Le Caïd* (1849) and *Songe d'une nuit d'été* (1850). In 1866 he produced *Mignon*, based on Goethe's novel *Wilhelm Meister*; it was followed by *Hamlet* (1868). In 1871 he succeeded D. F. E. Auber as director of the Paris Conservatoire, and became a well-known teacher. The style of Thomas's music is graceful and elegant, similar to the lighter aspects of the style of Gounod, and he wrote brilliantly for the coloratura soprano voice. He died in Paris on Feb. 12, 1896. See H. de Curzon, *Ambroise Thomas* (1921). (E. Lr.)

**THOMAS, DYLAN MARLAIS** (1914–1953), Welsh poet who at the time of his death was held to be one of the most remarkable poets of his generation, was born in Swansea, on Oct. 27, 1914. In 1934 he published his first volume of verse, *Eighteen Poems*, which was immediately recognized by Edith Sitwell and others as the work of an original and individual talent. There followed *Twenty-Five Poems* (1936); *The Map of Love* (1939); and *Portrait of the Artist as a Young Dog* (1940), a collection of humorous autobiographical sketches. Some of his finest work was in *Deaths and Entrances* (1946) and *In Country Sleep* (1952). The theme of all his poetry is the celebration of the divine purpose which he sees in all human and natural processes. In some of the best of his later poems he seeks, like Henry Vaughan and Thomas Traherne, to recapture the child's innocent vision of the world. His poems are, in a good sense, impersonal. The wit and humour that made him an enchanting companion come out in his sketches and short stories, mainly based on memories of his Swansea childhood. In his last completed work, the radio play *Under Milk Wood* (1954), the vision of the poet and the fun of the entertainer can be seen, for the first time, working together. His gifts as a broadcaster and the legend of his wild conviviality helped to spread his reputation. Thomas led a reckless life, but it never interfered with his sober devotion to his "craft and sullen art." He died, in New York City, where he had been rehearsing and revising *Under Milk Wood*, on Nov. 9, 1953.

*Collected Poems* was published in 1952 and his broadcast scripts were collected in *Quite Early One Morning* (1954).

See J. Ackerman, *Dylan Thomas: His Life and Work* (1964); C. FitzGibbon, *The Life of Dylan Thomas* (1965). (G. S. F.)

**THOMAS, GEORGE HENRY** (1816–1870), Union general in the American Civil War (*q.v.*), known as "the Rock of Chickamauga" for his unyielding defense at the Battle of Chickamauga (1863). Born in Southampton County, Va., on July 31, 1816, he graduated from the U.S. Military Academy at West Point in 1840. He served in the artillery in the war against the Seminole Indians in Florida and in the Mexican War (1846–48). After the war he served as an instructor at West Point and in 1855 was a major in the 2nd Cavalry. When the Civil War broke out in 1861 he remained loyal to the Union.

In command of an independent force in eastern Kentucky, on Jan. 19, 1862, he attacked the Confederate general Felix Zollicoffer at Mill Springs, and gained the first important Union victory in the west. He served under Gen. Don Carlos Buell and was offered, but refused, the chief command in the anxious days before the Battle of Perryville. Under Gen. W. S. Rosecrans he was engaged at Stone River and was in charge of the most important part of the

maneuvering from Dechard to Chattanooga. At the Battle of Chickamauga, Sept. 19, 1863, he held the left wing against heavy odds. He succeeded Rosecrans in command of the Army of the Cumberland shortly before the great victory of Chattanooga, in which Thomas and his army played a conspicuous part. When Gen. J. B. Hood broke away from Atlanta in the autumn of 1864, menaced Sherman's long line of communications, and endeavoured to force Sherman to follow him, Sherman left to Thomas the difficult task of dealing with Hood. At the Battle of Franklin, Nov. 30, 1864, Thomas' force, under General Schofield, checked Hood long enough to cover the concentration at Nashville. Thomas then attacked (Dec. 15-16, 1864) and inflicted on Hood the worst defeat sustained in the open field by any army on either side during the war. Thomas was made a major general in the regular army and received the thanks of Congress. After the war he commanded military departments in Kentucky and Tennessee until 1869, when he was placed in charge of the division of the Pacific with headquarters at San Francisco. He died there March 28, 1870.

**THOMAS, JAMES HENRY** (1874-1949), British statesman and trade union leader, was born at Newport, Monmouthshire, on Oct. 3, 1874, the illegitimate son of a domestic servant. An errand boy from the age of 9, at 15 he became a railway engine cleaner. He later moved to Swindon (headquarters of the Great Western Railway) and was prominent there in local government and as a trade unionist. He became national president of the Amalgamated Society of Railway Servants in 1904 and was later its organizer and assistant secretary. In 1911 he conducted the negotiations with the employers when the threat of a general railway strike secured recognition of the unions throughout the industry. In 1913 three railway unions amalgamated to form the National Union of Railwaymen (NUR) and in 1917 Thomas became general secretary.

From 1910 to 1936 Thomas was Labour member of Parliament for the railway town of Derby. Although he declined to join Lloyd George's coalition government in World War I (believing that he could be of more use outside), he was made a privy councillor in 1917. After the war he was closely connected with many industrial disputes. In 1919 his union was involved in the first general stoppage on the railways. In the "triple alliance" of miners, railwaymen, and other transport workers he had a moderating influence and received much of the blame when the other members of the alliance failed to support the miners' strike in 1921. He was equally prominent in the general strike of 1926 and throughout pressed for a peaceful settlement. As an industrial negotiator he was a shrewd opportunist. He did well for his members and believed that he was entitled in return to do well for himself. Caricatures showed him in evening clothes, smoking a large cigar. He was aggressively working-class in manner, but not in habits or beliefs.

Alongside his union activities (he was president of the Trades Union Congress in 1920 and of the International Federation of Trade Unions from 1920 to 1924), Thomas continued in politics. In the 1924 Labour government he was secretary of state for the colonies; in that of 1929 he was lord privy seal and minister for employment, but failed to take any effective measures to deal with the depression. He became secretary of state for the dominions in 1930, retaining office when J. Ramsay MacDonald formed his National government in August 1931 and was one of the two senior ministers to leave the Labour Party with MacDonald. This involved severing his connection with the NUR. He returned to the Colonial Office in 1935, but in 1936 he was held partly responsible for premature release of information about the budget and resigned both from office and from Parliament. He died in London, on Jan. 21, 1949. His autobiography *My Story* was published in 1937.

See G. Blaxland, *J. H. Thomas* (1964).

(R. J.)

**THOMAS, NORMAN (MATTOON)** (1884- ), U.S. social reformer and six times the Socialist Party's candidate for president, was born in Marion, O., on Nov. 20, 1884, the oldest of six children of a Presbyterian minister. Thomas spent his freshman year in college at Bucknell University and then transferred to Princeton, where he became a member of the debating team and was valedictorian of the class of 1905.

Following a trip around the world and some social settlement work, Thomas matriculated at Union Theological Seminary. While a student there, he served as associate minister of the Brick Presbyterian Church, Fifth Avenue, New York City, with Henry Van Dyke. He married Frances Violet Stewart in 1910.

After graduating from the seminary in 1911 and being ordained as a Presbyterian minister, he accepted the pastorate of the East Harlem Church and the chairmanship of the American Parish, a settlement house in one of the poorer sections of the city. In his work in his church and the parish during the next few years he became increasingly convinced that the major political parties were offering no adequate solution to the problems of poverty and social injustice that he found on every hand, nor to the problem of war. He became a pacifist and opposed U.S. participation in World War I. When Morris Hillquit ran for mayor of New York City in 1917 on the Socialist ticket Thomas actively supported him and later joined the Socialist Party.

Leaving his East Harlem posts in 1918, Thomas became secretary of the newly formed Fellowship of Reconciliation. In 1921 he became associate editor of the influential weekly, *The Nation*, and in 1922 co-executive director of the League for Industrial Democracy, a position he held until the mid-1930s. Thomas was an eloquent and effective speaker and during this period he lectured extensively among college and civic groups in all parts of the country. He was one of the founders of the American Civil Liberties Union and remained throughout his life a staunch defender of civil liberties.

Thomas ran for governor of New York on the Socialist Party ticket in 1924; for mayor of New York City in 1925 and 1929; and for president of the United States six times—in 1928, 1932, 1936, 1940, 1944, and 1948. (See SOCIALIST PARTY [U.S.].) During this long period he helped forge the party's policies for meeting such major crises as the great depression of the 1930s, the rise of fascism and communism, and the outbreak of World War II.

In the following years, as chairman of the Postwar World Council, he devoted much of his energies to the problem of international peace. He wrote many books, including *A Socialist's Faith* (1951), *The Test of Freedom* (1954), *Mr. Chairman, Ladies and Gentlemen* (1955), *The Prerequisites for Peace* (1959), and *Socialism Re-examined* (1963). In the last named book, he examined the way in which national and world developments from 1917 had affected socialism in thought and action and his thinking about it.

See Harry Fleischman, *Norman Thomas* (1964). (H. W. L.)

**THOMAS, SIDNEY GILCHRIST** (1850-1885), English metallurgist and inventor of the "basic" (as contrasted with acid) process for steel production, was born in London on April 16, 1850. Educated at Dulwich College, he intended to study for the medical profession but the early death of his father changed his plans and, in 1867, he obtained a clerkship at the Marlborough Street police court. Fascinated by chemistry, he devoted all his spare time to study and eventually envisaged the possibility of dephosphorizing iron in the Bessemer converter. He became convinced that this could be effected by using a basic lining and forming a basic slag. Aided by his cousin, Percy Carlyle Gilchrist, a chemist at the Blaenavon ironworks, and with the support of Edward Pritchard Martin, manager of the works, his theories were confirmed by experiment. (See IRON AND STEEL INDUSTRY: *Thomas-Gilchrist Discovery*.) In 1879, tests in a 30-cwt. converter at the works of Bolckow, Vaughan, and Co. won general recognition, and Thomas resigned his clerkship to devote all his time to the development of his process. The heavy burden of study, business worries, and the constant round of visits to industrial plants, both at home and abroad, caused a serious deterioration in his health, and, while seeking medical advice in Paris, he died on Feb. 1, 1885.

(C. W. D.)

**THOMAS, (CHRISTIAN FRIEDRICH) THEODORE** (1835-1905), German-born conductor, a pioneer in the popularization of orchestral music in the United States, was born at Esens, Hanover, on Oct. 11, 1835. In 1845 he went to the U.S., where he earned a meagre living as a popular violinist. He first appeared as a conductor in New York in 1858 and four years later founded his own orchestra. In 1869 he began a series of tours in

the United States with his orchestra and consequently stimulated the formation of municipal orchestras in several cities. In 1876 he commissioned Wagner to write his "American Centennial March" for performance in Philadelphia, and in the following year he became conductor of the Philharmonic Society of New York. From 1891 to 1904 Thomas was the first conductor of the Chicago Symphony Orchestra. He introduced many new works in the U.S., including those of Tchaikovsky, Saint-Saëns, Bruckner, and Richard Strauss. He died in Chicago on Jan. 4, 1905.

See *Theodore Thomas: a Musical Autobiography*, ed. by G. P. Upton, 2 vol. (1905).

**THOMAS, WILLIAM ISAAC** (1863–1947), pioneer U.S. sociologist, who specialized in social psychology as applied to cultural analysis and personality development, was born on Aug. 13, 1863, in Russell County, Va. After graduating from the University of Tennessee, Knoxville, in 1884, he taught English there and at Oberlin (O.) College for ten years. Turning to sociology, he received his Ph.D. in 1896 at The University of Chicago, where he studied physiology, neurology, philosophy, and social psychology. He taught sociology consecutively at The University of Chicago, the New School for Social Research, New York City, and Harvard, and was a consultant at Yale. He died on Dec. 5, 1947, in Berkeley, Calif.

Thomas' *Source-Book for Social Origins* (1909) and *Primitive Behavior* (1937) reflected his interest in ethnography. His *Sex and Society* (1907) was the first fully secular approach to the subject written by an American sociologist. His major work, *The Polish Peasant in Europe and America*, 5 vol. (1918–21), prepared with F. Znaniecki, illustrated his comparative approach to the study of nationalities and his analysis of social problems by means of personal history. *The Unadjusted Girl* (1923) and *The Child in America* (1928) were outstanding psychological studies of personality. His important methodological contributions were the technique of personal history, described in the "Methodological Note" to his *Polish Peasant*, and his later "point-by-point procedure," based on the contention that theoretical formulations in sociology must be regarded as tentative until checked and developed by further research.

(H. E. BAR.)

**THOMAS À KEMPIS** (c. 1380–1471) is renowned as the author of the *Imitation of Christ* (q.v.), which, except for the Bible, has been the most influential book in Christian literature. Thomas Hemerken was born in the Rhineland town of Kempen—thus "of Kempen" (à Kempis)—in 1379 or 1380. In 1392 he was sent to continue his education at Deventer, Netherlands, a centre of Catholic education and piety and headquarters of the learned and devout Brethren of the Common Life (q.v.), founded by Gerhard Groote (q.v.). Deeply influenced for seven years by this religious atmosphere, and especially by Florentius Radewyns, Groote's successor, Thomas decided to enter the Augustinian Canons of the Windesheim congregation at Mt. St. Agnes, near Zwolle, where his brother John was prior and where he was to live almost continuously for more than 70 years. He took his vows in 1408, was ordained priest in 1413, and after a most devout and virtuous life died on Aug. 8, 1471.

Thomas, small of build, was capable and diligent in his work, yet impractical in worldly affairs. Although kind and gracious with others, he was extremely reserved and preferred to be alone with his books. He devoted his life to copying manuscripts (Bible, missal, books of devotion), to writing (39 ascetical and historical works), and to directing novices. Although it is disputed, he is most probably the author of the *Imitation of Christ*. In his writings he is certainly the best representative of the *devotio moderna*; he stresses the interior, affective, and ascetical (rather than the exterior, speculative, and mystical), and moderate, not extreme, austerity.

A critical edition of Thomas' *Opera Omnia* was published in seven volumes by M. J. Pohl (1902–22).

See G. de Montmorency, *Thomas à Kempis and His Book* (1907);

**THOMAS STEEL:** see CONVERTER STEEL.

**THOMISM** refers both to the doctrinal system of St. Thomas Aquinas and to the explanations and developments made by his followers. The main phases in the philosophical and theological tradition of the Thomistic school are the personal synthesis of St. Thomas, the work of the great commentators, and the modern revival.

**Aquinas' Position.**—Although making respectful use of Aristotle and the Platonists, Augustine and the Fathers, Aquinas developed a distinctive position. His originality was shown in treating existence (*esse*) as the supreme act or perfection of being in God as well as in created things, in reserving the creative act to God alone, in denying the presence of matter in angels, and thus in distinguishing between God and creatures by a real composition of existence and essence as principles in all created beings. Also characteristic was his teaching that the human soul is a unique subsistent form, substantially united with matter to constitute human nature (see SUBSTANCE). Aquinas maintained that the immortality of the human soul can be strictly demonstrated, that there is a real distinction of principles between the soul and its powers of knowing and willing, and that human knowledge is based upon sense experience leading to the mind's reflective activity. He held that both man and lower creatures have a natural tendency or love toward God, that supernatural grace perfects and elevates our natural abilities, and that blessedness consists formally in knowing God Himself, a knowledge accompanied by our full love of God. (See also AQUINAS, SAINT THOMAS; PHILOSOPHY, HISTORY OF; *Patristic and Medieval Philosophy: Western Philosophy*.)

This coherent but complex body of Thomistic doctrines was critically explained and developed during subsequent centuries. Views of St. Thomas on individuation and the localization of angels, man's nature and the unity of the world, appeared among the theses condemned in 1277 by Bishop Étienne Tempier at Paris and by Archbishop Robert Kilwardby at Oxford. At stake were the manner and extent of using Aristotle and his Arabian commentators in explaining Christian theology. The later 13th century was crowded with "correctorial" literature—treatises attacking and defending basic positions of St. Thomas, especially on the unicity of the human substantial form and the distinction of essence and existence. His precise meaning was lost even by some Thomists, who treated essence and existence as distinct things and overlooked the unifying relation between the substantial form and existence.

**Commentators.**—Encouragement toward consulting Aquinas' own writings came with the adoption of his doctrine by the Dominican Order (1278, 1279, 1286), his canonization by Pope John XXII (1323), and the special place accorded to his works at the Council of Trent. The scientific task of analyzing his thought was executed by a line of devoted commentators during the period 1400–1650. The first was the Dominican John Capreolus (c. 1380–1444), called "the prince of the Thomists," who recognized the need to make a direct integral study of the texts of St. Thomas. In his *Four Books of Defenses of the Theology of St. Thomas Aquinas*, Capreolus made a systematic use of the sources against the Scotists and Ockhamists (see DUNS SCOTUS, JOHN; OCKHAM, WILLIAM). Another major Dominican commentator was Tommaso de Vio, Cardinal Cajetan (q.v.), who made elaborate expositions of St. Thomas' *Summa theologiae* and *On Being and Essence*. He made his own restatement of the Thomistic arguments and drew upon many other writings of St. Thomas. Cajetan's independence was displayed in his work *On the Analogy of Names*, where he proposed the influential division of kinds of analogy into inequality, attribution, and proportionality, as well as in his opinion that the human soul's immortality can be supported only by probable reasons.

The classical commentary on St. Thomas' *Summa contra gentiles* was done by the Dominican Francesco Sylvestri of Ferrara (c. 1474–1528), who showed the importance of this work for the relation of faith and philosophy, the meaning of person, and the

desire of God. After the mid-16th century, the Thomistic commentators became involved in the intricate theological controversies on grace and premotion. Highly systematized presentations of opposing views were introduced into the commentaries on the *Summa theologiae* made by the Spanish Dominican theologian Domingo Bañez and the Spanish Jesuit authors Francis Toletus and Gabriel Vázquez. But the new Renaissance tendency to give separate treatment to philosophical and theological issues, as well as the pressures of seminary education, undermined the usefulness of the commentary form of approach to St. Thomas. A new trend is present in the Dominican John of St. Thomas (1589–1644), who issued a separate *Philosophical Course* and then a *Theological Course* in Thomistic thought. Using the framework of logic, philosophy of nature, and metaphysics, John assembled the philosophical teachings of St. Thomas under these systematic headings and reformulated the material for students who would then study theology. There were original features in his logic, including the distinction between formal and objective concepts and the stress on intentional signs.

**Modern Thomism.**—Throughout the 17th and 18th centuries, Thomism continued to be presented in philosophy and theology courses or manuals, especially in the Dominican Order. Most Thomistic manuals of this period were watered with the opinions of other Schoolmen and remained remote from modern problems. In most Catholic seminaries and universities of the early 19th century, eclecticism was the rule and more attention was paid to Descartes, Locke, and Wolff than to Aquinas. The modern revival of authentic Thomism began at this time in Italy. Vincent Buzzetti (1777–1824) and the Jesuit teacher Serafino Sordi (1793–1865) were instrumental in urging a direct study of the text of Aristotle and Aquinas. The revolutions of 1848 had a decisive influence upon both the Holy See and the Society of Jesus toward finding sound principles on God, man, and society in the works of St. Thomas. In editions of their philosophy manuals appearing after 1850, this renewal of Thomistic thought was advocated by three influential Jesuit writers in Italy and Germany: Luigi Taparelli d'Azeglio, Matteo Liberatore, and Joseph Kleutgen. Their own positions in epistemology, metaphysics, and social theory remained eclectic, but they did give impetus to the work of studying St. Thomas and the other Schoolmen in the light of modern intellectual and social issues.

Decisive support for this movement came with Pope Leo XIII's encyclical *Aeterni Patris* (1879). It noted the importance of sound doctrine for meeting today's problems and called for a restoration of the Christian philosophy of the Fathers and medieval Doctors, augmented where necessary by the reliable advances of modern research. Leo asked especially for a recovery of the wisdom of St. Thomas, whom he hailed as "the special bulwark and glory of the Catholic Faith." This program required an accurate historical study of St. Thomas himself and his major commentators, combined with a readiness to use the evidences and resources of modern learning and science. St. Thomas was declared the universal patron of Catholic schools, and a canon (1366, par. 2) in the new Code of Canon Law (1917) required philosophy and theology teachers to adhere to the method, doctrine, and principles of St. Thomas. This established the special authority of the Common Doctor in the church's teaching institutions, without impairing the recovery of all the other sources of Christian thought, the careful discussion of commonly recognized difficulties, and the effort to evaluate modern teachings.

Thomists of the 20th century concentrated upon two major tasks: a historical investigation of St. Thomas' doctrine in its medieval context, and a rethinking of that doctrine in reference to contemporary problems. Pioneer historians were Pierre Man- donnet and Martin Grabmann, who investigated the life of Aquinas, the canon of his writings, and his historical relationships. The setting of Thomistic doctrine in the wider medieval intellectual currents was described by Maurice De Wulf and Étienne Gilson. The latter also brought out the basic role of existence in Thomistic metaphysics, which he contrasted with other historical forms of metaphysics. Some general presentations of Thomistic thought were made by showing the development of the principles

of act and potency in the major areas of philosophy. The Dominican R. Garrigou-Lagrange stressed the problem of God and providence; A. Sertillanges, another Dominican, made the act of creation central to his exposition; the Jesuit Martin D'Arcy brought out the dynamic and affective aspects in the mind of Aquinas.

At Louvain University, Désiré Cardinal Mercier and his associates concentrated on the challenge of modern thought for Thomism. They treated the epistemological issue at the outset of philosophy, so that metaphysics might have the support of a well-founded realism. The aim of Joseph Maréchal was to reformulate the major thinkers, especially St. Thomas, in terms of the mind's dynamic affirmation of being and ultimate reference to the reality of God. Francesco Olgiati used a metaphysical realism of substance to establish the critical relevance of Thomism to Cartesian and empiricist thinkers. How to unite the various kinds of methods and knowledges in a human order was the main concern of Jacques Maritain, but he also applied the Thomistic concept of person and community to the problem of democracy.

After World War II, Thomists faced three major tasks: to develop an adequate philosophy of science, to take account of the phenomenological and psychiatric findings on man, and to evaluate the ontologies of existentialism and naturalism.

**THOMOND, EARLS AND MARQUESSES OF: see O'BRIEN.**

**THOMPSON, SIR BENJAMIN** (COUNT VON RUMFORD) (1753–1814), British-American scientist particularly noted for his researches on heat, and a founder of the Royal Institution, was born at Woburn, Mass., on March 26, 1753. In 1766 he was apprenticed to a storekeeper in Salem, Mass., and became interested in chemical and mechanical experiments and in engraving. On the evacuation of Boston by British troops in 1776 he went to London, where he was appointed to a clerkship in the office of the secretary of state. Within several months he was advanced to the post of secretary of the colony of Georgia and in 1780 became undersecretary of state. During this period he continued his scientific pursuits, however, and in 1779 was elected a fellow of the Royal Society. The explosive force of gunpowder, the construction of firearms, and a system of signaling at sea were subjects which particularly interested him. On the resignation of Lord North's administration Thompson left the civil service and went to Austria. At Strasbourg he was introduced to Prince Maximilian, afterward elector of Bavaria, and was invited by him to enter the civil and military service of that state. Having obtained permission from the British government to accept the prince's offer and having received the honour of knighthood from George III, he remained at Munich 11 years as minister of war, minister of police, and grand chamberlain to the elector. During his stay in Bavaria he reorganized the Bavarian Army, improved the conditions of the industrial classes, did much to suppress mendicancy, and also contributed a number of papers to the *Philosophical Transactions*.

In 1791 he was created a count of the Holy Roman Empire and chose his title of Rumford from the name of the American township to which his wife's family belonged. In 1795 he visited England, where he lost all his private papers including the materials for an autobiography. In London he investigated methods for curing smoky chimneys and for improving fireplace construction.

For a short time he was recalled to service in Bavaria, but in 1798 he returned to England. That year he presented to the Royal Society his celebrated "Enquiry Concerning the Source of Heat Which is Excited by Friction," in which he regarded heat as a mode of motion, as opposed to the then current view that it was a material substance. (For discussions of Rumford's experiments and conclusions see *ENERGY: Heat as a Form of Energy*; *HEAT: The Nature of Heat*.)

In 1799, with Sir Joseph Banks, Thompson projected the establishment of the Royal Institution, which received its charter from George III in 1800, and selected Sir Humphry Davy as scientific lecturer there. He was founder and first recipient of the Rumford Medal of the Royal Society, founder of the Rumford Medal of the American Academy of Arts and Sciences, and founder of the Rumford professorship at Harvard University. Rumford died at Auteuil, near Paris, on Aug. 21, 1814. His complete works, with a memoir by George H. Ellis, were published by the American Academy of Arts and Sciences in 1870-75.

**BIBLIOGRAPHY.**—James A. Thompson, *Count Rumford of Massachusetts* (1935); Allen French, *General Gage's Informers* (1932); E. Lehrburger (E. Larsen), *An American in Europe* (1953).

**THOMPSON, SIR D'ARCY WENTWORTH** (1860-1948), Scottish biologist whose classic work *On Growth and Form* (1917; new edition, 1942), written in rich literary style, exemplifies best his great erudition in physical and natural sciences, ancient and modern languages and the humanities. He was born in Edinburgh on May 2, 1860. After graduating at Trinity College, Cambridge, he became professor of natural history at University College, Dundee, and then at St. Andrews University, holding the chair for 64 years. Thompson was a fellow (1916), vice-president (1931-33), and Darwin medalist (1946) of the Royal Society, president of the Classical Association (1929), knighted (1937), and honoured by learned institutions the world over. For more than 50 years he was a leading member of national and international bodies investigating sea fisheries.

In *On Growth and Form* growth and structure in organisms are expressed in mathematical and physical terms and an important "theory of transformation" developed—that one species evolves into another not by successive minor changes in individual body parts but by large-scale transformations involving the body as a whole. Sir D'Arcy Thompson's other works include *A Glossary of Greek Birds* (1895; new edition, 1936), *Science and the Classics*, etc. (1940), and *A Glossary of Greek Fishes* (1947).

He died at St. Andrews on June 21, 1948.

See Ruth D'A. Thompson, *D'Arcy Wentworth Thompson* (1958). (A. D. P.)

**THOMPSON, FRANCIS** (1859-1907), English poet, whose best-known poem, "The Hound of Heaven," describes the divine pursuit of the human soul, was born at Preston, Lancashire, on Dec. 18, 1859. He was the son of Charles Thompson, a doctor, and the nephew of Edward Healy Thompson, the friend of Cardinal Manning and professor of English literature at the Catholic university in Dublin. After his father became a convert to Roman Catholicism, Francis was educated in the Catholic faith at Ushaw College. In 1877 he proceeded to Owen's College, Manchester, to study medicine. He took more interest in Aeschylus, Blake, and De Quincey's *Confessions of an English Opium Eater* than in his work, however; and, having failed the examinations three times, he went to London in November 1885 to seek a livelihood. Ill-health drove him to opium, and poverty reduced him to selling matches and newspapers. Eventually he found light work with a Leicester square bootmaker and wrote his first poems. In 1888 Wilfrid Meynell published two poems in *Merry England*, which aroused the admiration of Browning. Discovering the young author on the verge of starvation, the Meynells induced him to enter a hospital, aided him through his long convalescence and in 1893 arranged for the publication of his first volume, *Poems*, which was highly praised by Coventry Patmore, among others. *Sister Songs* (dedicated to the Meynells' children) followed in 1895, and *New Poems* (dedicated to Patmore) in 1897. From 1893 to 1897, apart from short intervals, Thompson lived near the Franciscan monastery in Pantasaph, North Wales. He died in London on Nov. 13,

1907, of tuberculosis, and was buried in the Catholic cemetery at Kensal Green.

Thompson's language is customarily orotund, ornate, and far-fetched; too often the reader is aware of the poet's self-conscious posturing. The common comparison with Richard Crashaw is misleading. The older poet, though he has something of Thompson's equivocal sensuousness, displays greater care for the meaning of words and maintains a more consistent dignity. Subject aside, the kinship is rather with the Keats of *Endymion*. Thompson is, undeniably, a poet of the "aesthetic" 1890s. His simpler poems (e.g., about children) are frequently marred by a mawkishness of which the poet seemed perversely proud. It is likely that his place in literature will depend entirely upon "The Hound of Heaven," where language and subject matter are more properly matched, and which, by virtue of its dramatic quality, is in fact nearer in spirit to the religious poetry of the 17th century (cf. George Herbert), though in this too the somewhat florid religiosity of the 1890s may occasionally repel the reader.

Thompson also wrote several prose works, including *Health and Holiness* (1905), *Life of St. Ignatius Loyola* (1909), *Life of Blessed John Baptist de la Galle* (1911), and *Essay on Shelley* (1909). His *Literary Criticisms* were edited by T. L. Connolly (1948). Thompson's *Works* were edited by W. Meynell, 3 vol. (1913); *Poems* were reprinted in 1 vol. (1937); *Selected Poems* (1908) includes an obituary by W. Meynell.

**THOMPSON, SIR JOHN SPARROW DAVID** (1844-1894), Canadian prime minister, was born at Halifax, Nova Scotia, on Nov. 10, 1844, of Irish descent. A lawyer, he was also for a time official reporter for the debates of the Nova Scotia legislature. In 1877 he was elected to the legislature for Antigonish as a Conservative and was named attorney general a year later. In May 1882 he became premier of Nova Scotia but left office in July when his government was defeated. For the next three years he served as a judge of the provincial Supreme Court.

He was called to Ottawa in September 1885 to become minister of justice in the government led by Sir J. A. Macdonald. During the following years he defended the government with great skill in several politico-religious controversies, including those occurring after the execution of Louis Riel (q.v.) in 1885, and the passage of the Jesuit Estates Act, 1888-89. He served as legal adviser to the British delegation in the negotiations leading to the Bayard-Chamberlain Treaty of 1888 regulating the North Atlantic fisheries, later rejected by the U.S. Senate.

On Dec. 5, 1892, he became prime minister of Canada, and held the office until his death two years later. During this period he was one of the arbitrators in the Bering Sea seal fishery dispute, 1893. His career was cut short by his sudden death on Dec. 12, 1894, at Windsor Castle in England, a few minutes after having been sworn in by Queen Victoria as a member of the Imperial Privy Council. (D. M. L. F.)

**THOMPSON, RANDALL** (1899- ), U.S. composer known for his choral music, was born in New York City on April 21, 1899. He studied at Harvard University with W. Spalding, E. B. Hill, and A. T. Davison, and later with Ernest Bloch. He taught at Wellesley College and at the University of California (Berkeley), was director of the Curtis Institute of Music, Philadelphia (1939-41), and head of the music division at the University of Virginia, and was professor of music at Princeton University (1946-48). Later he joined the staff of Harvard. He composed three symphonies (1930-49), of which the second was particularly successful. His chamber music is remarkable for its sense of form and of counterpoint. His vocal works, notably *Alleluia for a cappella choir* (1940) and *Testament of Freedom* to words by Thomas Jefferson, for men's voices and orchestra (1943),

achieved great popularity. His one-act opera *Solomon and Balkis* was produced at Cambridge, Mass., in 1942. He also wrote an oratorio, *The Passion According to St. Luke* (1965). (N. Sy.)

**THOMPSON, WILLIAM TAPPAN** (1812–1882), U.S. humorist remembered for his realistic character sketches of Georgia-Florida backwoodsmen, was born Aug. 31, 1812, in Ravenna, O. He early moved to Georgia, where as a self-made man whose education came from the printing press, he identified himself with Georgia life and culture. In 1838 he founded the *Augusta Mirror*, a literary magazine. Discovering that the South would not support literary periodicals, he turned in 1850 to newspaper editorship, founded the *Savannah* (Ga.) *Morning News*, and continued as its editor until his death in Savannah on March 24, 1882.

A Democrat throughout his editorial career, he typified the ideals, attitudes and prejudices of middle-class Georgians.

Influenced by Augustus Baldwin Longstreet, his personal friend, Thompson wrote amusing dialect letters which were collected in 1843 as *Major Jones' Courtship*; the book achieved nationwide popularity. Other volumes followed. Thompson had a demonstrable influence on Mark Twain, Richard Malcolm Johnston, and Joel Chandler Harris, his literary protégé. His popular antebellum humour is accepted as convincing Georgia dialect and as realistic local colour.

See also Walter Blair, *Native American Humor* (1937); Henry Prentice Miller, "The Background and Significance of *Major Jones' Courtship*," *Georgia Historical Quarterly*, xxx, 267–296 (1946).

(H. P. M.)

**THOMSEN, CHRISTIAN JÜRGENSEN** (1788–1865), Danish archaeologist who developed the three-age system of pre-history (Stone, Bronze, and Iron), was born in Copenhagen on Dec. 29, 1788. The son of a well-to-do merchant, he succeeded his father as manager of the business until it ended in 1840. An early hobby of coin collecting soon led him to an interest in prehistoric antiquities. In 1816 he was appointed secretary of the royal commission set up to preserve and collect Danish antiquities and the first curator of the Museum of Northern Antiquities (later the National Museum) in Copenhagen. In his first years at the museum (he remained as director for the rest of his life) Thomsen devised and demonstrated the three-age system in his arrangement of the antiquities in the collection. The scheme was published (1836) in his *Ledetraad til nordisk Oldkyndighed* (English translation, *A Guide to Northern Antiquities*, 1848), which served as a guide to the museum. Thomsen died in Copenhagen on May 21, 1865.

See also SCANDINAVIAN ARCHAEOLOGY.

(T. M.N.)

**THOMSEN, (HANS PETER JÖRGEN) JULIUS** (1826–1909), Danish chemist best known for his work on thermochemistry, was born in Copenhagen on Feb. 16, 1826. From 1847 to 1856 he taught chemistry at the technical high school there, and from 1856 to 1866 was on the staff of the military high school. In 1866 he was appointed professor of chemistry at the University of Copenhagen and retained that chair until 1891, when he retired. He died in Copenhagen on Feb. 13, 1909.

In the course of his thermochemical work Thomsen made about 3,500 calorimetric measurements, determining the heat evolved or absorbed in a very large number of chemical reactions. His publications in this field were collected in *Thermochemische Untersuchungen* (four volumes, 1882–86). He verified Kirchhoff's equation connecting the change of heat of a reaction with temperature and the specific heats of the reactants and resultants, and also used his measurements to confirm Guldberg and Waage's theory of mass action (1867). Thomsen introduced the term "avidity" to indicate the tendency of an acid to unite with a base and used his results to draw up the first table of relative strengths of acids. He also made accurate determinations of the atomic weights of oxygen and aluminum. In 1853 he devised a process for manufacturing soda from cryolite, which was first worked on a large scale in 1857 and made him rich.

See obituary notice, *Proceedings of the Royal Society* (1910–11); E. Thorpe, Thomsen Memorial Lecture, *Journal of the Chemical Society* (1910).

**THOMSON, SIR CHARLES WYVILLE** (1830–1882), Scottish naturalist especially remembered as a student of the biological conditions of the depths of the sea and as director of the scientific staff in the "Challenger" expedition (q.v.). He was born at Bonyde, West Lothian (Linlithgow), on March 5, 1830, and was educated at Edinburgh University. At first a botanist by profession, he was lecturer in botany at Aberdeen University from 1851 to 1852, and professor of botany at Marischal College from 1852 to 1853. His leanings, however, were toward zoology, and between 1853 and 1868 he taught natural sciences at Cork and at Belfast. After a short time (1868–70) as professor of botany at the Royal College of Science, Dublin, he became (1870–79) professor of natural history at Edinburgh.

Thomson's interest in crinoids (sea stars and feather stars) was stimulated by the results of the dredgings of the Norwegian zoologist Michael Sars in the deep sea off the Norwegian coasts. With W. B. Carpenter, Thomson succeeded in obtaining the loan of HMS "Lightning" and "Porcupine" for successive deep-sea dredging expeditions in 1868 and 1869. These operations showed that animal life exists in abundance down to depths of 650 fathoms, that all invertebrate groups are represented (largely by Tertiary forms previously believed to be extinct), and, moreover, that deep-sea temperatures are by no means so constant as was supposed, but vary considerably, indicating an oceanic circulation. The results of these expeditions were described in *The Depths of the Sea* (1873).

In the "Challenger" circumnavigation expedition, Thomson sailed at the end of 1872 as director of the scientific staff, the cruise lasting three and one-half years. On his return he received many academic honours, and was knighted. In 1877 he published two volumes of a preliminary account of the voyage (*The Voyage of the "Challenger"* and *The Atlantic*) and, with John Murray, superintended the preparation of the full reports until the time of his death, at Bonyde, Scotland, on March 10, 1882.

**THOMSON, CHRISTOPHER BIRDWOOD THOMSON, BARON** (1875–1930), British soldier and statesman who became the Labour Party's military expert during the 1920s, was born at Nasik, India, on April 13, 1875, the son of Maj. Gen. D. Thomson. Educated at Cheltenham College and at the Royal Military Academy, Woolwich, he served in the Mashonaland campaign (1896) and in the South African War (1899–1902). Instructor of the military engineering school at Chatham from 1902 to 1905, he went to the Staff College, Camberley, in 1909, and to the War Office in 1911. During World War I he was military attaché and chief of the British military mission in Rumania (1915–16), served in Palestine (1917–18) and was on the Supreme War Council at Versailles (1918). Having attained the rank of brigadier general, he resigned from the service in 1919 in protest against the Allied intervention in Russia. He then joined the Labour Party and, as military expert, accompanied the commissions of inquiry dispatched by that body to Ireland (1920) and to the Ruhr (1923). At the general elections of 1922 and 1923, he was an unsuccessful candidate for Parliament. In 1924 he became secretary of state for air in the first Labour government, with a seat in the cabinet, and was raised to the peerage. He returned to the Air Ministry from 1929 to 1930 in the second Labour government. A graceful and effective speaker, Lord Thomson also possessed marked literary gifts and his publications included *Old Europe's Suicide* (1920) and *Victors and Vanquished* (1924). He was killed in the crash of the airship R101 at Beauvais, France, on Oct. 5, 1930.

**THOMSON, ELIHU** (1853–1937), U.S. engineer and inventor whose work led to the development of the alternating-current electric motor, was born in Manchester, Eng., March 29, 1853. In 1858 he moved to Philadelphia, Pa., with his parents and later taught chemistry and mechanics there. In his early years of research, Thomson's association with Edwin J. Houston led to scientific and financial success with the development of an arc lighting system. Thomson's most notable discovery was that of alternating-current repulsion phenomena, and his work in this field laid the basis for successful alternating-current motors. He made the first high-frequency generator in 1890, and shortly afterward

the first high-frequency transformer. Other well-known inventions included the three-coil generator, electric welding by the incandescent method, and the watt-hour meter.

Thomson made useful contributions in the field of radiology and pioneered in making stereoscopic X-ray pictures. He was the first to propose a mixture of helium and oxygen for workers in caissons and tunnel borings. He published numerous articles in scientific and engineering journals, and, as the holder of more than 700 patents, received many awards. He died March 13, 1937, at Swampscott, Mass.

See D. O. Woodbury, *Beloved Scientist: Elihu Thomson, a Guiding Spirit of the Electrical Age* (1944). (T.S. C.)

**THOMSON, SIR GEORGE PAGET** (1892– ), English physicist, a co-winner of the Nobel Prize in Physics in 1937 for his work on the diffraction of electrons in crystals, was born in Cambridge, Eng., May 3, 1892, the only son of Sir Joseph John Thomson (q.v.), the eminent physicist and Nobel Prize winner (1906). After taking his degree at Trinity College, Cambridge, in 1914, he saw service in World War I in France and was later a member of the British war mission in the U.S. At the end of the war he worked in the Cavendish Laboratory at Cambridge. In 1922 he was appointed professor of natural philosophy in the University of Aberdeen, and it was there that he did work on the diffraction of electrons in crystals which established the wave properties of moving electrons and also had important practical applications. By means of the electron diffraction camera it is possible to determine the arrangement of the atoms in many solids and liquids, and this threw much light on the question of stress and resistance in metals. From 1930 to 1952 Thomson was professor of physics in the Imperial College of Science and Technology, University of London. During and after World War II he was one of the principal scientific advisers to the British government and to the UN Atomic Energy Commission. He was elected a fellow of the Royal Society in 1930 and was awarded the Hughes Medal in 1939 and the Royal Medal in 1949; he was knighted in 1943. In 1952 he became master of Corpus Christi College, Cambridge, retiring in 1962.

He wrote *Applied Aerodynamics* (1919); *The Atom* (1930; 6th ed., 1962); *Wave Mechanics of Free Electrons* (1930); *Theory and Practice of Electron Diffraction* (with William Cochran, 1939); *The Foreseeable Future* (1955); and *J. J. Thomson and the Cavendish Laboratory in His Day* (1965); he also helped revise his father's *Conduction of Electricity Through Gases* (3rd ed., 2 vol., 1928–33). (W. J. Br.; X.)

**THOMSON, JAMES** (1700–1748), Scottish poet, gave penetrating and eloquent expression to the national imagination when it was fired by Newtonian science, and by the prospect of great political power based on commercial and maritime expansion.

Though a Scot by birth (at Ednam, Roxburgh, on Sept. 11, 1700) and by education (at Jedburgh Grammar School and Edinburgh University), and although, when he went to London in March 1725, it may have been to seek a reputation in the pulpit, Thomson set himself to contribute rather to the English than the Scottish literary tradition. He was an admirably painstaking writer, as may be seen from the bibliographical history of his masterpiece, *The Seasons*. Making his living in London as a tutor, Thomson published *Winter* in 1726, *Summer* in 1727, *Spring* in 1728, and the whole poem, including *Autumn*, in 1730; but until 1746 he repeatedly revised the work, and the final version differed greatly from the first. The poem deserved this labour, and profited by it. For it was a revolutionary new departure. The novelty lay less where all but the latest commentators have found it, in its subject matter, than in its structure. Indeed the subject matter of *The Seasons*, as the first sustained work of "nature-poetry" in English, if it contributed to the poem's popularity and reputation up to about 1850, later helped to make it increasingly, and unjustly, neglected. What was more striking to Thomson's earliest readers was his audacity in binding his poem together without any aid from "plot" or developing narrative action, and therefore in defiance of the Aristotelian beginning, middle, and end, as interpreted by the neoclassicist critics.

In diction, as in invention, Thomson was an innovator. In his

choice of words he followed the precedent of *Paradise Lost* in drawing heavily on the Latinate element in English vocabulary, and by using also Latinate syntax he was able, again like Milton, to compose his blank verse by verse-paragraphs rather than line by line. Partly he was able to profit by the Miltonic model, which has proved treacherous for other poets, by applying the style to quite un-Miltonic subjects, the appearance of the countryside changing as seasons change. Yet it is wrong to regard *The Seasons* as simply a descriptive poem. In the first place Thomson was interested, when he recorded images from external nature, in the state of mind which these inspired or responded to in the observer; and he thus opened the way to the Romantic, Symbolist, and modern methods of conveying states of feeling by implication. And secondly, in particular when he dealt with the atmospheric effect of different kinds of weather, Thomson learned from the discoveries of landscape painters on the one hand, and on the other from the speculations of Sir Isaac Newton in his *Opticks*, and of other scientists, on the nature of light and the physiology of human vision. This last enthusiasm became splendidly explicit in *A Poem to the Memory of Sir Isaac Newton* (1727):

Even Light itself, which everything displays  
Shone undiscovered, till his brighter mind  
Untwisted all the shining robe of day: . . .

Nowadays, when fear and envy of the prestige of the natural sciences causes men of letters to declare that there can be no compromise between the power of science and the power of poetry, Thomson's elated sympathy with Newtonian science, and his conviction that scientist and poet must collaborate in the service of God known through his Creation, is only an embarrassment. Yet Thomson did far more than versify scientific findings; his imagination was fully engaged with the scientific endeavour, and throughout *The Seasons* scientific method penetrated the texture of his language. It has been pointed out, for instance, how, in the poetic diction of Thomson and some others, a circumlocution like "finny kind" for "fish" exemplifies, by its stock epithet and pressure toward generalization, the habit of mind that produced also the botanical classifications of Linnaeus. And when, in the poem to the memory of Newton, Thomson catalogues the colours of the spectrum, his intoxication with the grandeur of Newton's analysis produces in the last line a profoundly imaginative near-pun on "violet":

Then the pure blue, that swells autumnal skies,  
Ethereal played; and then, of sadder hue,  
Emerg'd the deepened indigo, as when  
The heavy-skirted evening droops with frost;  
While the last gleamings of refracted light  
Died in the fainting violet away.

When compared with the contempt and derision heaped on scientists by Swift and Pope, Thomson's sympathy with their endeavours appears not only to have been justified by later history but also to represent a more generous and positive movement of the spirit.

Moreover his sympathy with classification and scientific law does not obstruct, rather it enhances, his vivid apprehension of the particular instance, and the tumultuous beauty of organic life. Thus, the fish—

Long time he, following cautious, scans the fly,  
And oft attempts to seize it, but as oft  
The dimpled water speaks his jealous fear.  
At last, while haply o'er the shaded sun  
Passes a cloud, he desperate takes the death  
With sullen plunge. At once he darts along,  
Deep-struck, and runs out all the lengthened line;  
Then seeks the farthest ooze, the sheltering weed,  
The caverned bank, his old secure abode;  
And flies aloft, and flounces round the pool,  
Indignant of the guile.

(*The Seasons: Spring*: ll. 426–435)

The undignified word "flounces," cooperating smoothly with stilted locutions like "takes the death" and "indignant of the guile," reveals a range of diction much wider than, for example, Wordsworth's; and the acting out, preeminently through rhythm, of the turbulence of this encounter between human and inhuman life en-

forces a perception which is not Wordsworthian. Thomson has been too often applauded for having done only what was later done better by poets of the Romantic revival.

Thomson sympathized with the Whig opposition to the administration of Sir Robert Walpole. His allegiance to the opposition group gathered round Frederick, prince of Wales, is manifest as early as 1729, in his *Britannia. A Poem*; and it informs his ambitious poem in five parts, *Liberty* (pt. i, ii, and iii, 1735; pt. iv and v, 1736), as well as his drama, *Agamemnon* (1738). For *Liberty*, "a poetical landscape of countries, mixed with moral observations on their government and people," Thomson drew on the writings of Shaftesbury, but also on his experiences in 1730-31, when accompanying the son of Sir Charles Talbot, solicitor general, on his travels in France and Italy. Talbot secured a sinecure for Thomson (1733), but on Talbot's death in 1737 Thomson was in less comfortable circumstances until his friend, Lord Lyttelton, gave him another sinecure in 1744. To these years belong *Edward and Eleanor*, the production of which was banned because of the political innuendo in *Agamemnon*; a preface to Milton's *Areopagitica* (1738); and, with David Mallet, *The Masque of Alfred* (1740; with music by Thomas Augustine Arne), which contains his famous ode "Rule Britannia."

Thomson's confidence that "Britons never will be slaves" (and never had been, since Druidical and Anglo-Saxon times) went with his conviction that the nation had a duty to pursue policies of commercial imperialism. It is hard not to be wise after the event, and reflect upon the enslavement of the majority resulting from unrestricted commercial competition and exploitation. But Thomson's patriotism was not hypocritical, nor was it complacent. Britain indeed had come, as he thought,

To this deep-laid indissoluble state  
Where wealth and commerce lift the golden head,  
And o'er our labours liberty and law  
Impartial watch, the wonder of a world!  
(*The Seasons: Spring*: ll. 846-849)

Yet it could be maintained in this condition only by unremitting exertion. Thomson's *Castle of Indolence* (1748) is an allegory of what happens once exertion is slackened, when the wizard Indolence by his enchantments undoes all the good wrought by the hero, Sir Industry. *The Castle of Indolence*, however, owes its popularity to a response the opposite of what the author intended. In Spenserian stanzas, and up to a point in archaic Spenserian diction, the poem is beguiling for its mellifluous evocation of just that slothful ease which Thomson intended to reprove; and it is generally held that Thomson's imagination was here engaged at a level he was not conscious of, connected with the sedate epicureanism which he indulged particularly in his last years, in retirement at Richmond. He died there on Aug. 27, 1748, leaving his tragedy *Coriolanus* to be first presented in 1749.

**BIBLIOGRAPHY.**—*The Complete Poetical Works*, ed. by J. Logie Robinson, Oxford Standard Authors Series (1908; reprinted 1951), includes an invaluable variorum edition of *The Seasons*, but excludes the dramas. Biography and criticism in Dr. Johnson's *Lives of the Poets* (1781); G. C. Macaulay, *James Thomson*, English Men of Letters Series (1908); D. Grant, *James Thomson: Poet of "The Seasons"* (1951). Exhaustive study of Thomson's sources in contemporary scientific works and books of travel has been carried out by A. D. McKillop, in *The Background of Thomson's Seasons* (1942), and *The Background of Thomson's Liberty* (1951). See also J. Arthos, *The Language of Natural Description in 18th-Century Poetry* (1949); M. H. Nicolson, *Newton Demands the Muse* (1946); J. H. Hagstrum, *The Sister Arts: the Tradition of Literary Pictorialism and English Poetry from Dryden to Gray* (1958).

(D. A. DE.)

**THOMSON, JAMES** (pseudonym BYSSHE VANOLIS, or B. V.) (1834-1882), Scottish poet, remembered for his long, pessimistic poem, *The City of Dreadful Night*, was born at Port Glasgow, Renfrew, on Nov. 23, 1834. His father, a merchant seaman, became incurably ill in 1840; his mother died in 1842, and thereafter he was cared for and educated at an orphanage. In 1850 he entered the Royal Military Academy, Chelsea, to train as an army schoolmaster, and in 1851 was sent to Ireland as a pupil-teacher. There he met Charles Bradlaugh, the secularist leader, and fell in love with the 14-year-old daughter of an army sergeant, who died two years later.

In 1862, Thomson was discharged from the army for a minor offense, and went to London, where at first he lived with the Bradlaughs, working as a clerk, and writing essays, poems, and stories, many of them published in the *National Reformer*, a secularist workingmen's weekly founded by Bradlaugh, in which first appeared *The City of Dreadful Night* (1874). Always poor, often morose in temper, an atheist, pessimist, and dipsomaniac, he made few friends, eventually quarreling even with Bradlaugh. However, one of his admirers, Bertram Dobell, the bookseller and man of letters, arranged for the publication of his most important volume, *The City of Dreadful Night, and Other Poems* (1880).

An admirer and translator of Leopardi, Thomson did not balance his atheism with any kind of social optimism. The keynote of *The City of Dreadful Night* is: "No hope could have no fear." Monotonous in its gloom, stiff and sometimes wordy in its rhetoric, this poem nevertheless conveys in an almost Baudelaireian way that image of the bleakness and inhumanity of the modern great city which was to be a central theme for such later poets as T. S. Eliot. No other Victorian poem displays more bleakly the dark underside of an age of change, excitement, and hope.

Salt, *Life of James Thomson* (1898; rev. ed., 1914); I. Walker, *James Thomson: a Critical Study* (1950); W. D. Schaeffer, *James Thomson (B. V.): Beyond The City* (1965). (G. S. F.)

**THOMSON, SIR JOHN ARTHUR** (1861-1933), British naturalist known chiefly for his popular books and writings on biology, was born at East Lothian, Scot., on July 8, 1861, and was educated at the universities of Edinburgh, Jena and Berlin. He was, for a time, lecturer on zoology and biology at the school of medicine in Edinburgh, and in 1899 he became regius professor of natural history at Aberdeen university. Apart from his purely zoological work, chiefly on alcyonarians (soft corals, etc.), Thomson did much, both by his lectures and his numerous attractive books and writings, to popularize biological science, and he was indefatigable in his efforts to correlate science and religion. He was knighted in 1930 and died Feb. 12, 1933.

His publications include: *Outlines of Zoology*, 9th ed. (1944); *The Wonder of Life* (1914); *The System of Animate Nature*, Gifford Lectures (1920); *Science, Old and New* (1924); *The New Natural History* (1925); *Science and Religion* (1925).

**THOMSON, JOSEPH** (1858-1895), Scottish explorer and the last who, during the late 18th and part of the 19th centuries revealed the interior of Africa, was also the first who served the chartered companies developing the new discoveries. Born on Feb. 14, 1858, at Penpont, Dumfries, he studied geology at Edinburgh University under Archibald Geikie, and in 1878 was appointed geologist and naturalist to the Royal Geographical Society's expedition to east-central Africa, under Keith Johnston. Johnston's early death left Thomson in command and, with David Livingstone's Chuma as his headman, he led the expedition to the north end of Lake Nyasa and thence to Lake Tanganyika. An attempt to reach the Congo was thwarted by the hostile Warua, and he returned to the coast by Tabora, discovering Lake Rukwa on the way.

In 1882 the Royal Geographical Society launched an expedition led by Thomson to probe the shortest route from the sea to the Nile headwaters, a way hitherto barred by the Masai. Thomson traveled from Mombasa by way of Mounts Kilimanjaro and Kenya, discovered Lake Baringo, and, surviving numerous encounters with the Masai, reached Lake Victoria on Dec. 10, 1882.

In 1885 he undertook a mission for the National African (afterward the Royal Niger) Company, securing trade treaties with the sultans of Sokoto and Gando; in 1888 he traveled privately in Morocco and in 1890 he entered the service of Cecil Rhodes' British South Africa Company, on whose behalf he made trade and mining agreements in what is now Zambia. Thomson returned to Gatelawbridge in 1891 in poor health. He died in London on Aug. 2, 1895.

Thomson's maxim when traveling was the Italian saying: "Who goes slowly, goes safely; who goes safely, goes far," and he was notable for his abhorrence of force. He wrote *To the Central*

*African Lakes and Back* (1881), *Through Masai Land* (1885), and *Travels in the Atlas and South Morocco* (1889).

See J. B. Thomson, *Joseph Thomson, African Explorer* (1896), which contains a full list of his writings. (D. Mn.)

**THOMSON, SIR JOSEPH JOHN** (1856–1940), English physicist, the discoverer of electrons and the recipient of the 1906 Nobel Prize in Physics for his work on the conduction of electricity through gases, was born at Cheetham Hill, near Manchester, on Dec. 18, 1856. At the age of 14 he enrolled at Owens College, Manchester. In 1876 he went to Cambridge and entered Trinity College as a minor scholar; he remained a member of this college, in one capacity after another, during the rest of his life. In 1884 he was elected a fellow of the Royal Society and, upon the resignation of Lord Rayleigh, succeeded to the Cavendish professorship at Cambridge, a chair that he held until 1919.

Thomson's treatise on vortex rings, which won him the Adams Prize and which may be taken as an indication of his early interest in atomic structure, appeared in 1883. Ten years later, in 1893, his *Notes on Recent Researches in Electricity and Magnetism* appeared. This book covers results obtained after the appearance of James Clerk Maxwell's great *Treatise* in 1873, and is often alluded to as "the third volume of Maxwell." *A Text-book of Physics*, in four volumes, was the joint work of Thomson and John H. Poynting. These books had a wide use, as did Thomson's *Elements of the Mathematical Theory of Electricity and Magnetism* (1895; 5th ed., 1921).

In 1896, Thomson gave a course of four lectures at Princeton University. These summarized his researches on the *Discharge of Electricity Through Gases*. Several years later, at Yale University, he gave a series of six lectures on *Electricity and Matter* (1904) in which some keen suggestions looking toward atomic structure were offered. It was, however, between these two series of U.S. lectures that he accomplished the most brilliant work of his life. This was the highly original study of cathode rays, in which he

measured the ratio  $\frac{m}{e}$  (where  $m$  is mass and  $e$  the charge of an ion)

and discovered that its value is nearly 1,000 times less than in the electrolysis of liquids. He immediately proceeded to measure the charge of electricity  $e$  carried by various negative ions and found it to be the same in the gaseous discharge as in electrolysis. In this manner the fact was established that the particles which constitute cathode rays are much smaller than the smallest atoms known. They are the particles that are now called electrons. This discovery of a body smaller than the hydrogen atom was first announced in his Friday evening lecture at the Royal Institution on April 30, 1897.

In 1903 he published his most remarkable book, *Conduction of Electricity Through Gases*, described by Lord Rayleigh as a summary of "the work of Thomson's great days at the Cavendish laboratory." A later edition, in two volumes, was published in collaboration with his son, George Paget Thomson (*q.v.*), in 1928 and 1933.

Thomson's later researches led to an exceedingly important discovery, namely, a new method of separating different kinds of atoms and molecules. This consists in the use of "positive rays," the deflection of which in a magnetic or electric field varies, other things being equal, with the atomic weight. This idea, in the hands of Francis W. Aston, A. J. Dempster, and others, led to the discovery of many isotopes.

Thomson was president of the Royal Society from 1915 to 1920 and master of Trinity College from 1918 to 1940. He died in Cambridge on Aug. 30, 1940; his ashes were buried in Westminster Abbey. His autobiographical *Recollections and Reflections* was published in 1936.

**THOMSON, VIRGIL** (1896– ), U.S. composer, conductor, and music critic, whose forward-looking ideas, largely de-

rived from the French composers of the early 20th century, stimulated new lines of thought among the musicians of his time. Born in Kansas City on Nov. 25, 1896, he studied at Harvard University and with Nadia Boulanger in Paris, where he also became known in the circles of painters and writers. Gertrude Stein was the librettist of his *Four Saints in Three Acts* (Hartford, Conn., 1934), an operatic burlesque in which the title is deliberately misleading, for the opera is actually in four acts and there are more than a dozen saints in the cast. This was followed by *The Mother of Us All* (New York City, 1947), also to Gertrude Stein's libretto, on the subject of the woman suffrage movement. Thomson's instrumental music, like his operas, veers from hymnal solemnity to sophisticated playfulness. It includes two symphonies; the symphonic poems *The Seine at Night* (1948), *Wheatfield at Noon* (1948), and *Sea Piece with Birds* (1952); and a cello concerto (1950) and a flute concerto (1954). He also composed *Five Songs* for voice and orchestra, to poems of William Blake (1952), chamber music, sacred choruses, piano pieces, and the film music to *Louisiana Story* (1948). He was music critic for the *New York Herald Tribune* (1940–54) and published several collections of his critical articles, offering a penetrating assessment of the contemporary musical scene. His autobiography, *Virgil Thomson on Virgil Thomson*, was published in 1966.

See K. O. Hoover and J. Cage, *Virgil Thomson: His Life and Music* (1959). (N. Sv.)

**THONBURI**, a city and province in central Thailand on the west bank of the Mae Nam Chao Phraya River across from Bangkok. Area of province 174 sq.mi. (450 sq.km.); pop. (1960) 559,432. Approximately one-quarter of the city's population (1960, 403,818) is of immediate Chinese descent, 6% being China-born. Connected by three bridges with Bangkok, the city has in effect become a suburb of the capital.

Thonburi is a centre for sawmilling, rice milling, and light manufacturing industry. Many of its people live on *khlongs* or canals, on which "floating markets" can be seen. The most prominent landmark is Wat Arun, the Temple of Dawn. During the reign of King Takh Sin (1767–82), Thonburi was the national capital. Paddy production for the province averages about 40,000 metric tons annually. (G. W. Sk.)

**THONET, MICHAEL** (1796–1871), Austrian manufacturer, pioneer in the industrialization of furniture manufacture, was born July 2, 1796, at Boppard in the Rhineland. A humble artisan, Thonet by the age of 40 developed a system of steam-bent veneers, glued four or five together, from which he made complete chairs, light and curvilinear. Similar techniques were simultaneously used, but less freely, by the German-born Henry Belter in New York City, and bent plys of wood, pegged but not glued, were used by the ancient Egyptians. Thonet's inventiveness attracted Prince Metternich, another native Rhinelander, who in 1842 invited Thonet to settle in Vienna, where for the next five years he worked on the masterly neorococo interiors of the Liechtenstein Palace.

Some of Thonet's work there included bent, solid wood, formed by methods familiar to wheelwrights; these pieces were subcontracted through the important firm Carl Leistler and Son, decorating the palace.

By 1856 Thonet had perfected the bending of solid wood and was ready for mass production. From then on, success attended his enterprises. He died on March 3, 1871, in Vienna where his firm was producing furniture in hitherto unheard-of quantities, around 400,000 pieces annually. Solid bentwood furniture, never out of production, was again made fashionable by Le Corbusier in the 1920s. (Er. K.)

**THONGA** (properly TSONGA), Bantu speakers who inhabit the southern coastal plain of Mozambique, with some representatives in Swaziland and the Republic of South Africa. Culturally and linguistically the Thonga are related to other Mozambique Bantu such as the Chopi, Lenge, and Inhambane Tonga. In the 1960s this group of related peoples numbered more than 1,369,000.

The Thonga were formerly organized as independent tribes, each occupying its own territory and named for a powerful patrilineage that dominated the tribe. In the early 19th century they were

conquered by Nguni (*q.v.*) raiders from the south who created a number of small kingdoms, the most important of which was Shangana. In the late 19th century the Thonga came under Portuguese rule and lost their political identity.

The Thonga live in scattered homesteads; inheritance and succession are patrilineal. Polygyny is permitted and bridewealth (*q.v.*) is paid. A man's livestock is apportioned among his wives for their support and for eventual inheritance by the children of each wifely household. The principal heir is the senior son of the chief wife. Children also have claims on their mother's lineage; they are allowed to joke with their mother's brother and may make free with his property. Divorce has been rare; widows are inherited by males of the dead husband's lineage.

The Thonga are agriculturalists (cassava is the staple) and pastoralists; fishing and hunting are of minor importance. Women do much of the agricultural work though some men grow cash crops. Most Thonga depend on wage labour for cash, many migrating to Rhodesia or the Republic of South Africa to find work.

Many Thonga are Christian; others adhere to the traditional, highly ritualistic religion. Men enter adult life through an initiation school and circumcision. Members of each lineage propitiate their own ancestral spirits. Illness and other misfortune are usually attributed to the breaking of a tabu, to the anger of ancestors, or to sorcery; detection of the agent is by divination. Sorcery is most commonly blamed on women married into the lineage, rarely on lineage mates.

See H. A. Junod, *The Life of a South African Tribe*, 2 vol. (1962); A. M. Duggan-Cronin, *The Bantu Tribes of South Africa*, vol. iv, *The Vathonga* (1936). (E. Co.)

**THOR**, a deity common to all the early Germanic peoples, a great warrior represented as a red-bearded, middle-aged man of enormous strength, an implacable foe to the harmful race of giants (demons) but benevolent toward mankind. His figure is generally secondary to that of Odin, who in some traditions is his father. But in Iceland and indeed, perhaps, in all northern countries except among the royal families he was apparently worshiped more than any other god. There is evidence that a corresponding deity named Thunor or Thonar was worshiped in England and on the continent, but little is known about him. Thor's name is the Teutonic word for thunder, and it is the thunderbolt that is represented by his hammer, the attribute most commonly associated with him. The hammer, Mjollnir, had many marvelous qualities, including that of returning to the thrower like a boomerang; it is frequently found on runic stones and funerary steles. Thor has close affinities with Jupiter, as is attested by the name of the fifth day of the week, "Thor's day" throughout the Germanic world and *dies Jovis* in the Roman. See also GERMANIC MYTHOLOGY AND HEROIC LEGENDS.

See J. A. MacCulloch in *The Mythology of All Races*, vol. ii, *Eddic*, pp. 68-96 (1930).

**THORAX**, the anatomical term for the chest, in man and other mammals that part of the body between the neck and abdomen. The bony framework consists of the 12 thoracic vertebrae, 12 pairs of ribs and the sternum (breastbone). It contains the chief organs of respiration and circulation; namely, the lungs, some air passages, the heart and great vessels. Below, it is bounded by the diaphragm. The bony framework is encased with muscles, fat, and cutaneous tissues. (See SKELETON, VERTEBRATE.)

In insects the thorax is the middle of the three major divisions of the body. It is composed of three parts, each of which commonly bears a pair of legs; the rearward two parts usually bear each a pair of wings. (F. L. A.; X.)

**THORBECKE, JOHAN RUDOLF** (1798-1872), the inspirer of the Netherlands constitution of 1848 and subsequently three times prime minister. He was born at Zwolle, in Overijssel, on Jan. 14, 1798. After graduating at Leiden, he spent some time at German universities and became a lecturer at Giessen and at Göttingen. He published a treatise "On the Essence and Organic Character of History" in 1824 and some "Considerations Regarding Law and the State" in 1825. He was then appointed supernumerary professor at Ghent; but the Belgian revolution of 1830 drove him back to Leiden, where he became a professor in the

faculty of law. Though he did not teach constitutional law, he won unrivaled authority in this field. His *Aanteekening op de Grondwet* ("Annotation to the Constitution," 1839; second edition 1841-43, manifesting the development of his liberal ideas) was of fundamental importance for the constitution of 1848.

Thorbecke was prime minister of the Kingdom of the Netherlands from Nov. 1, 1849, to April 19, 1853; from Feb. 1, 1862, to Feb. 10, 1866; and finally from Jan. 4, 1871, to his death, at The Hague, on June 5, 1872. For his policy see NETHERLANDS, THE: History. His liberalism was influenced by German Romantic ideas of the historical-juridical school of K. F. Eichhorn and F. K. von Savigny. In his denial of the theory of the sovereignty of the people he also differed from the French rationalist view. Nor was there any anticlericalism in his outlook: his truly liberal attitude toward Roman Catholics was most objectionable to Conservative Protestants. The opposition which he frequently encountered was provoked, however, not only by the expression of his principles, but also, partly, by his rigid and haughty personality.

See K. H. Boersema, *Johan Rudolf Thorbecke* (1949); I. J. Brugmans, *Thorbecke*, 3rd ed. (1958). (H. A. Bo.)

**THOREAU, HENRY DAVID** (1817-1862), U.S. writer, poet and philosopher who invested his life in his native village to the end of enacting the doctrines of New England Transcendentalism as expressed by his friend and associate Ralph Waldo Emerson (*q.v.*), among others. A naturalist chiefly in the sense that nature was his field of action and contemplation, Thoreau was concerned primarily with the possibilities for human culture provided by the American natural environment. He believed that "All things invite this earth's inhabitants/To rear their lives to an unheard-of height"; to meet this "expectation of the land" (*Collected Poems of Henry Thoreau*, edited by Carl Bode, p. 135, Packard and Co., Chicago, 1943), he domesticated ideas garnered from classical, oriental, English and the then current romantic literatures in order to extend U.S. libertarianism and individualism beyond the political and religious spheres to those of social and personal life. In a society which Henry James said was "not fertile in variations" (F. O. Matthiessen, *The James Family*, p. 441, Alfred A. Knopf, Inc., New York, 1947), Thoreau pioneered the life of an artist and like Emerson opened vistas to new vocations and intrinsic successes. "The life which men praise and regard as successful is but one kind. Why," he asked in *Walden*, where his example was the answer, "should we exaggerate any one kind at the expense of the others?" (This and all following quotations from the prose works of Thoreau—the standard Walden edition, *The Writings of Henry David Thoreau*, 1906—are by permission of Houghton Mifflin Company, Boston.) In a commercial, conservative, expedient society rapidly becoming urban and industrial, he upheld the right to self-culture, to an individual life shaped by inner principle. An artist whose life was his material, he demanded for all men the freedom to follow unique life styles, to make poems of their lives and living itself

an art. Wholeness and being were his aims, not the limited fulfillment of specialization; the artisan was to become an artist, the partial man "spherical," the factitious man authentic. In a restless, expanding society dedicated to practical action, he demonstrated the uses and values of leisure, contemplation and rootedness.

Thoreau's writing not only enriched the New England landscape with human associations, but taught men how to take up the land without despoiling it—with their imaginations. He established the tradition of nature writing developed by John Burroughs and John Muir, and his pioneer study of the human uses

THE GRANGER COLLECTION

THOREAU. DAGUERRETYPE BY BEN. JAMIN D. MAXHAM. 1856

of nature profoundly influenced such conservationists and regional planners as Benton MacKaye and Lewis Mumford. More important, his life, so fully expressed in his writing, has had a pervasive influence because it was an example of moral heroism and an example of the continuing search for a spiritual America. One of the classic U.S. writers, he became a culture hero because he had shown that "the intrinsigence of the spiritual unit . . . alone gives edge to democracy" (*The Seven Arts*, II, July, 1917, p. 385).

**Early Life.**—Although Thoreau playfully linked his genealogy with that of the first discoverers of America, the Viking descendants of Thor, and characterized himself as a follower of the "trade of heroism," Thoreau's outward life offered little adventure for the annalist. The son of John Thoreau, whose father had emigrated from the Channel Islands, and of Cynthia Dunbar, daughter of a Congregational minister, he was born July 12, 1817, in the rural village of Concord, where his unsuccessful father finally settled and set up a small graphite pencil factory. This home industry, which Thoreau dutifully served all of his life, and his mother's boardinghouse, where he lived except for the intervals at the Emersons' and at Walden pond, were his permanent background.

Thoreau prepared at the Concord academy, and, at great sacrifice to his family, entered Harvard college in 1833. There he came abreast of his age, encountering both the intellectual heritage of the 18th century, which he would soon abandon, and the new thought that provided the philosophical basis for his experiment in life. Jones Very, a minor Transcendentalist poet, was his tutor in Greek; Orestes Brownson (*q.v.*), soon to become a Transcendentalist publicist, helped him with German during a schoolteaching vacation; Edward Tyrel Channing, professor of rhetoric, assigned compositions in which Thoreau sketched his conception of the superior man and recorded the increasing Transcendental tendency of his thought. A good student but indifferent to the rank system and preferring to use the library to his own ends, he graduated midway in the class of 1837. But, as he announced in his commencement piece on "The Commercial Spirit," with its scorn for getting and spending, with its plea for cultivating "the moral affections" and the powers to enjoy and admire the "wonderful" world, he was eager to follow a vocation for which few of his classmates had the inclination, preparation or heart.

Emerson called Thoreau to that vocation. During commencement week he delivered his challenging Phi Beta Kappa address, "The American Scholar." In it he summoned the younger generation to follow his own calling—that of the independent intellectual at the service of the republic—and to fulfill in action the program for nurturing American genius and culture that he had outlined in *Nature* (1836). "He shall see," he promised the self-reliant truth seeker, "that nature is the opposite of the soul, answering to it part for part. . . . Its beauty is the beauty of his own mind. Its laws are the laws of his own mind. Nature then becomes to him the measure of his attainments. So much of nature as he is ignorant of, so much of his own mind does he not yet possess. . . . in fine, the ancient precept, 'Know thyself,' and the modern precept, 'Study nature,' become at last one maxim." This "correspondence" between the subjective and the objective, the inner and the outer, the indwelling spirit in man and the immanent spirit in nature, were at the core of the Transcendentalist faith. To discover the identities between man and nature, to translate the external world into consciousness, to humanize science by making fact flower into truth, was now the work of the scholar. Thoreau undertook this exploration of "whole new continents and worlds within" when, on his return to Concord, Emerson suggested that he keep a journal; eventually running to 39 manuscript volumes, the journal became the principal archive of Thoreau's arduous experience of assimilating nature to himself.

**After Harvard.**—Immediately following his graduation Thoreau kept a school; privately he continued his apprenticeship to his chosen craft by writing poems and literary essays. He began his long service as lecturer and curator for the Concord Lyceum and published his first poem in the newly launched magazine the *Dial*, edited by Margaret Fuller (*q.v.*) and Emerson. He fell in love with Ellen Sewall of Scituate and was rejected. Unwilling to

postpone his life and already lamenting that he was an Apollo enslaved to Admetus, he gave up teaching; on Emerson's request, he went to live with his mentor, exchanging his skills as handyman and editorial assistant on the *Dial* for the freedom to pursue his own work.

Emerson turned Thoreau to nature writing by prompting Thoreau's first major essay, "Natural History of Massachusetts"; he severely pruned Thoreau's poems; and he tried to bring his protégé to market by sending him as tutor to the William Emersons of Staten Island, where he might find it easier to sell his wares in New York. Thoreau, however, was unsuccessful. As he put it, his essays were not "companionable"; "Paradise (To Be) Regained" destroyed the popular assumptions of utilitarian progress, and "A Winter Walk," one of the best of his early spiritual excursions, was better fitted for the *Dial*. Confirmed in his distaste for city life, disappointed by his failure, and in debt, he returned home and with Yankee brevity noted in his autobiographical record: "Made pencils in 1844."

**The Walden Years.**—In 1845, Emerson provided the few acres Thoreau needed for his Walden experiment, which was to make good his losses and permit him at last to have his life while living it; but Emerson did not approve what seemed to him a withdrawal into solitude and an abdication of the "Napoleonic" leadership he expected of his "brave Henry." For Thoreau, however, going to nearby Walden pond was an act of independence, the act of precipitating his fate (in *Walden* he began the account of his residence there on Independence day). Not only did he wish to solve by simplicity and subsistence farming his economic problems as a writer, he wished by means of his intimacy with nature to meet "the great facts of his existence" and to live an uncommitted life open to spirit. To him the landscape of his new life bordered the "Elysian fields"; measured by his ecstatic communion with nature, the two years at Walden were the great occasion of his life.

Thoreau left the pond in September 1847 in order to manage the Emerson household during Emerson's absence on a lecture tour in Great Britain and because, with *A Week on the Concord and Merrimack Rivers* completed, he felt ready to retrieve his early failure. He was unable to find a publisher, however, and the publication of this, his first book, was delayed until 1849, when Thoreau issued it at his own expense. It was so poorly received that Thoreau resisted the appeals to publish *Walden* until the debt he had incurred was paid. Just as poorly received were his attempts as a lecturer to find a public. Having "not made it worth any one's while" to buy his delicately woven wares, as he explained in *Walden*, he tried to "avoid the necessity of selling them." He no longer tried to maintain himself by writing; he returned to the pencil factory and to surveying, his occupations for the rest of his life.

**The Fruits of Walden.**—Thoreau's greatest books, *A Week* and *Walden*, were indebted to the Walden years. Companion volumes, the first covers Thoreau's spiritual history from 1839 to 1849, the second the years from 1845 to 1854. *A Week* takes its joyousness from the vacation mood and spiritual communion of these early years and the years at Walden where it was written. An excursion in thought, its narrative framework is the boat trip Thoreau had made with his beloved brother John in 1839; the literal adventure carried with it his thoughts on religion, friendship, politics, reform, art and nature—the experience of a decade of exploration. The book enacts Thoreau's belief that "the order of things should be somewhat reversed; the seventh day should be man's day of toil . . . and the other six his Sabbath of the affections and the soul,—in which to range this widespread garden, and drink in the soft influences and sublime revelations of Nature. . . ." A meandering, meditative book, successfully uniting action and contemplation; a series of days on the stream of consciousness; a voyage into America, to the headwaters of inspiration: *A Week* covers Thoreau's life from youth to maturity, from the easy availability of inspiration to the more conscious use of inspiration in the creation of art.

Thoreau's relation to nature in *A Week* was "one and continuous everywhere"; inspired, his life was "constantly as fresh as this

river." He was "a long-lived child/As yet uninjured by all worldly taint/. . . whose whole life is play." In *Walden*, he was the "mature soul of lesser innocence" who, "from the sad experience of his fate," had consciously earned "the ripe bloom of a self-wrought content" (Bode, p. 225).

*Walden* was begun in 1846-47, but was considerably modified and amplified in six revisions, material being incorporated almost until the time of publication in 1854. The book therefore did not literally record the *Walden* experience, for this experience was refracted by what Thoreau felt was the "decay" of the following years during which it was brought to completion. A symbolic book, then, treating his experience not so much retrospectively as prospectively, to the end of self-therapy and hope, *Walden* affirmed Thoreau's faith in "the unquestionable ability of man to elevate his life by conscious endeavor." By his definition, the book was a scripture, the sacred testament of a man living through the process of revelation; its myth, secured by the seasonal movement of the narrative from summer to spring, was that of a return to the springs of life—a fable of spiritual renewal.

**Later Writings.**—Thoreau's actual life in these and the remaining years did not bring renewal. Now his problem was a more difficult one than that of living by writing. His inspirational relation to nature itself had been broken by the deterioration of his friendship with Emerson, by his involvement in the antislavery movement, by the impurity that he felt was due to the coarse life required of the surveyor, and by the intense strain of the outdoor life and the scientific studies he imposed on himself. The goal of self-culture, he found, could not be fully realized in nature; personal and social relations were also necessary. The inevitable awareness of manhood had destroyed the unconsciousness of youth and, with it, the communion with nature he now desperately tried to regain by discipline.

Though his sense of losing his innocence and purity was great, his powers as a writer were increased by his more objective investigation of nature and by his social concerns. "Civil Disobedience," his most famous essay (it influenced Gandhi, among others), was his defense of the private conscience against majority expediency; published in 1849, it announced the moral intransigence of later essays such as "Slavery in Massachusetts" and "Life Without Principle," and those essays written in behalf of John Brown, who carried the political faith of the Transcendentalists to the conclusion of bloody action.

The finest essays, however, like his travel books (*The Maine Woods*, *A Yankee in Canada* and *Cape Cod*), were the fruit of a more strenuous undertaking, that of rediscovering and repossessing the aboriginal environment of America which had sustained his own spirit. Composed of his accounts of his three trips to Maine, in 1846, 1853 and 1857, *The Maine Woods* presents at its finest Thoreau's zest for outdoor adventure. Less symbolic than his other works (the essays were intended to be of practical help to campers), the book does however indicate his retreat from primitivism to the more human pastoralism of Concord. *A Yankee in Canada* took Thoreau into the country explored by the French discoverers whom he admired, but the old world institutions there provoked him to praise of the freer institutions of New England. *Cape Cod* introduced him to the first frontier, the sea, and enabled him to recount the history of the new world from the time of the Northmen, Cabot and Columbus to that of his own excursions; and the incidents of shipwreck made it possible for him to transform death into a passage to the last frontier, the spiritual west. At home, in Concord, with failing strength (the signs of fatal tuberculosis appeared as early as 1852) he laboured on his "Kalendar." His most grandiose project, it was to put on record all of his knowledge of nature's year as this knowledge had been mixed with human aspiration, growth and fruition—his, his countrymen's, and man's throughout history. He completed only "Autumnal Tints" and "Wild Apples"; appropriately they were essays on the values of maturity, an autumnal victory over the tragic loss of his springtime. The first is a paean to the flaming, courageous leaves that taught him how to die; the latter is a transparent parable of his own life and his desire to grow wild that he might, in Emerson's words, "yield that peculiar fruit which each

man was created to bear." These travels, in New England at large and in his own backyard, provided the inspiration for his final testament, "Walking." Walking had been his spiritual exercise; his holy land was the west. The west was the freedom, the "wild" that nurtured civilizations and men. This ecology of man and his environment was Thoreau's largest gift to America.

Thoreau did not relinquish civilization for primitivism; in the interests of human culture, he wished only to keep civilization open on one side that others, as he had, might bear their peculiar fruits. For health as well as because of his devotion to the west, Thoreau went to Minnesota in 1861. He died in Concord on May 6, 1862.

**Editions.**—The standard edition is *The Writings of Henry David Thoreau*, in 20 volumes (1906); vol. vi, *Familiar Letters*, was edited by F. B. Sanborn; vol. vii-xx, the *Journals*, were edited by Bradford Torrey and Francis Allen. *Consciousness in Concord*, edited by P. Miller (1958), contains the "lost" journal of 1840-41. Other sources are *Collected Poems of Henry Thoreau*, edited by Carl Bode (1943), and *The Correspondence of Henry David Thoreau*, edited by W. Harding and Carl Bode (1958).

**BIBLIOGRAPHY.**—*Biographical and Critical Studies*: H. S. Canby, *Thoreau* (1939); J. W. Krutch, *Henry David Thoreau* (1948); F. O. Matthiessen, *American Renaissance* (1941); Leo Stoller, *After Walden: Thoreau's Changing Views on Economic Man* (1957); Sherman Paul, *The Shores of America: Thoreau's Inward Exploration* (1958). Walter Harding (ed.), *Thoreau: A Century of Criticism* (1954), is a collection of critical essays. A bibliography compiled by T. H. Johnson can be found in *Literary History of the United States*, ed. by Robert E. Spiller et al., vol. iii, pp. 742-746 (1948). See also Floyd Stovall (ed.), *Eight American Authors: a Review of Research and Criticism* (1956); Walter Harding, *A Thoreau Handbook* (1959); M. Meltzer and W. R. Harding, *A Thoreau Profile* (1962). (S. PL.)

**THOREZ, MAURICE** (1900-1964), French Communist leader for 34 years. Born at Noyelles-Godault, in the Pas-de-Calais, on April 28, 1900, he became a coal miner at the age of 12, joined the Socialist Party in 1919, and moved into the Communist Party after the Socialists had split at the Congress of Tours (December 1920). He became party secretary for the Pas-de-Calais in 1923 and rose rapidly until in July 1930 he became secretary-general, after several terms in prison for agitation. He was elected to the Chamber of Deputies in 1932 and reelected in 1936. On the outbreak of World War II he was mobilized, but when the government banned the party because of its hostility to the war he left the army and went underground. He was tried *in absentia*, sentenced to six years' imprisonment, and subsequently deprived of his citizenship. In 1943 he went to the U.S.S.R.

At the Liberation, Thorez was pardoned by Gen. de Gaulle's government and, in November 1944, returned to France; in 1945 his French nationality was restored. He became a deputy again in 1945 and was reelected throughout the Fourth Republic. After being a minister of state under De Gaulle in November 1945, he was deputy prime minister under Félix Gouin and Georges Bidault in 1946 and under Paul Ramadier in 1947; but when the Communists voted against the government in May 1947, their ministers were dismissed. Thorez himself was soon suspected by Moscow of nationalism of Tito's kind, and was made to renounce it in 1948. He had a cerebral hemorrhage in October 1950, went to Moscow for medical treatment, and did not return until April 1953. Thorez was on the whole a Stalinist and after Khrushchev's denunciation of Stalin in 1956 he extolled the dead leader.

In 1958 the Communists failed to prevent De Gaulle's coming to power. In the ensuing elections the party lost heavily, but Thorez himself retained his seat. Thorez died on July 11, 1964, in a Soviet ship en route for Yalta. He published *Fils du Peuple* (1937) and *Une Politique de grandeur française* (1949).

(P. W. C.)

**THORFINN KARLSEFNI** (fl. 1002-07), Scandinavian leader of the first medieval expedition for the colonization of North America, was born in Iceland around 980. He must have been given his nickname at an early age, for *karlsefni* means "promising boy." His grandfather, Snorri Bjarnason, is a historical figure as one of the aristocrats who, about the year 900, led the westward-swarming Norwegians to Iceland. Many of them felt so pressed for stock-farming land by 986 that they fol-

lowed the lead of Eric the Red and migrated to Greenland. By the year 1000 there were probably more than 1,000 Scandinavian stock farmers in what is now the Julianehaab district of Greenland. Karlsefni, finally caught up in the westward sweep from Iceland, reached what was known as the eastern settlement of Greenland during the autumn 1003 with two ships and about 80 colonists. No doubt the ships would have continued to or beyond the western settlement had not Eric invited all hands to spend the winter with him at his farm, Brattahlid. From the *Saga of Eric the Red* it appears that there may have been a motive behind the hospitality. The saga tells of banquets, jollity and glowing talk of a country to the southwest, beyond the sea, that had been discovered three years before by one of Eric's sons, Leif, and named by him Vinland (*q.v.*). The impression one gets from the saga is that both father and son were persuasive, trying to divert the two Icelandic vessels from prosecuting a further northwestward colonization along the shore of Greenland, directing them instead toward Vinland, perhaps in part because the previous year Eric's son Thorstein had died in the western settlement, and his widow Gudrid had come to stay at Brattahlid. Eric now married her off to Thorfinn; and it was arranged that a Greenland ship would join the Icelandic ones and they would pick up Gudrid's property on their way to Vinland.

In the spring of 1004 [or, according to other historians, 1010 or 1020] about 130 men and women, in three vessels, with livestock and household goods, sailed from the eastern to the western settlement, picked up Gudrid's property, and crossed from the Greenland coast at Bear Island (Disko) toward Baffin Island, apparently striking that shore near Cape Dyer. They named the coast Helluland, meaning "Land of Flat Stones" (Flagstoneland) and continued to use this name as long as they saw no trees while coasting in a southerly direction. After crossing Hudson strait they saw trees and then called the shore Markland, meaning "Forest Land."

Farther south they came to a section which they took for Leif's Vinland district and which sounds in the narrative as if it probably was some part of the Gulf of St. Lawrence, perhaps the south shore. Reaching the heavily wooded region, the colonists built houses, made hay and spent the winter hunting and fishing, much as if they were still in Greenland; but they noted that the meadows were grassier and that the winter was shorter.

The first winter the Scandinavians met no people but the next summer they were visited by friendly natives with whom they traded and who, from the description, were Eskimos. After wintering in a different place, or perhaps scattered in several wintering places, they were again visited by natives, this time more numerous and no longer friendly. A battle ensued; the Europeans won it, but at the cost of some lives. Following still another winter, during which the colonists evidently thought things over, Thorfinn decided to return to Greenland. There was no longer unity among the colonists. Although all decided to abandon Vinland, they did not all head for Greenland and some, perhaps intending to reach Iceland, were shipwrecked on a western coast of Europe.

With his wife, and a son who had been born to them in Vinland, Thorfinn spent the winter of 1006-07 in Greenland. Later they returned to Iceland, where Thorfinn's family was already powerful.

Snorri, the Vinland-born son whom Thorfinn had named after his Norwegian grandfather, became the progenitor of a line of clergy. The clergy were not celibate in those days and their numerous descendants came to include two bishops during the first few generations—and bishops were nobility in both Greenland and Iceland under the new dispensation. In a genealogically minded modern Iceland, many people of consequence trace their descent, through Karlsefni, to the U.S. or to Canada; for though the Vinland of the 1004-05 wintering almost certainly was in Canada, some argue that one or both of the other winterings may have been in New England.

Among the persisting results of the Karlsefni voyage was a North American activity of the Roman Catholic Church in the Markland-Vinland region. There resulted, too, commerce between Greenland (*q.v.*) and Labrador (Markland) that is mentioned in

both Icelandic and Norwegian records as late as 1347. The seafarers of northwestern Europe never lost memory of coasts west of Greenland that stretch to the south. A theory developed that these coasts would curve eastward in the far south to connect with northern Africa. But in the period between the 13th and 15th centuries nobody seems to have been much interested in this knowledge until after Columbus had the idea that these lands beyond the Atlantic might be a northward extension of Marco Polo's rich Cathay.

**BIBLIOGRAPHY.**—Excellent scholarship on the Vinland voyages is found in the following three volumes by Halldór Hermannsson in the series, *Islandica, The Northerners in America* (1909), *The Problem of Vinland* (1936) and *The Vinland Sagas* (1944). On the historicity of the Greenland-Vinland sagas see Sir William A. Craigie, *The Icelandic Sagas* (1913). See also for history, Vilhjalmur Stefansson, *Greenland* (1942); H. R. Holand, *Explorations in America Before Columbus* (1956); R. A. Skelton, G. D. Painter, and T. E. Marston, *The Vinland Map and the Tartar Relation* (1965); "Vinland the Good Emerges from the Mists," *American Heritage*, vol. xvi, no. 6 (Oct. 1965); Count Eric Oxenstierna (trans. by Catherine Hutter), *The Norsemen* (1965); Farley Mowat, *Westviking: the Ancient Norse in Greenland and North America* (1965). **THORIANITE**, a strongly radioactive mineral with the idealized composition thorium dioxide, ThO<sub>2</sub>. It ordinarily contains more or less uranium in solid solution and is then transitional to the structurally related mineral uraninite (*q.v.*), UO<sub>2</sub>. Rare earths and radiogenic lead and helium also are present. Thorianite forms hard, black to brown isometric crystals of high specific gravity, 9.7-10. The mineral was originally found as waterworn grains and crystals in the gem gravels of Ceylon. It also has been found sparingly in the black sands of rivers and beaches in Alaska and other parts of the United States, Madagascar and Siberia. Varieties containing much uranium occur in pegmatites in Quebec and Ontario, and in serpentine at Easton, Pa. The refractory nature and the small supply of thorianite has restricted its commercial use as a source of thorium (see also MONAZITE). (Cl. F.)

**THORILD, THOMAS** (1759-1808), Swedish poet and critic who led the revolt against the influence of French classicism. Born April 18, 1759, at Svarteberg, Bohuslän, he studied at Lund and Uppsala. He visited England (1788-90). In 1793 he was banished from Sweden as a result of a political libel after the assassination of Gustavus III. He went to Germany and in 1795 was appointed professor and librarian at Greifswald, where he died Oct. 1, 1808. A born fighter, Thorild attacked the taste for French culture, writing unrhymed verse inspired by Ossian, Shakespeare, Klopstock, and Goethe. Among his best works is *Passionerna* (1785), a philosophical poem expressing a pantheistic feeling for nature. The powerful style of his prose essays resembles that of the old Swedish laws. His famous *En kritik öfver critiker* ("A Critique of Critiques," 1791-92) is a plea for positive literary evaluations. After his banishment he continued to write essays of which *Om kvinnökönets naturliga höghet* ("The Natural Greatness of Womanhood," 1793) is one of his best.

Thorild's collected works were first published in four volumes (1819-35). A critical edition by Stellan Arvidson was begun in 1932; volume iv appeared in 1946.

See A. Nilsson, *Thomas Thorild: en studie över hans livsaskadning* (1915); E. Cassirer, *Thorilds Stellung in der Geistesgeschichte des 18. Jahrhunderts*. (1941). (S. E.)

**THORITE**, a mineral consisting of thorium silicate, is one of the most important thorium minerals. The theoretical formula, ThSiO<sub>4</sub>, requires 81.5% of thoria, but analyses show only 50%-70%, there being also some uranium, cerium, etc. The mineral is almost always altered by hydration and is then optically isotropic and amorphous. Because of alteration and differences in composition, the specific gravity varies from 4.4 to 5.4. The colour is usually light brown, but in the gem variety known as orangite it is orange-yellow. It crystallizes in the tetragonal system and is isomorphous with zircon (*q.v.*). The mineral occurs as isolated crystals and small masses in the augite-syenite near Brevik in south Norway; also at Arendal, and in the gem gravels of Ceylon. Good crystals are found on Stove mountain, El Paso county, Colo. Thorite is mined commercially at Cripple Creek, Colo., and at Hall mountain, Idaho. (L. J. S.; W. F. Fg.; X.)

**THORIUM.** The radioactive metallic element thorium and its oxide are comparatively rare materials. In spite of this fact, they have played an important role in technology for many years and became the foundation of at least one large industry, the manufacture of gas mantles. The oxide is also important as an additive to metallic tungsten filaments for controlling metallurgical properties. In electronic devices thorium oxide is widely used as a source of primary electron emission. The advent of atomic energy, jet turbines, and rockets brought an unusual demand for new metals and alloys. Important alloys containing thorium were developed for improving the high-temperature strength of metals, in particular the magnesium base alloys.

Thorium has great potential use in nuclear reactors. Its abundance in the earth's crust is at least three times that of uranium. The particular advantage of the use of thorium in the field of atomic energy is as a "breeder" material. It functions in an atomic pile in such a way as to yield a net increase in atomic fuel; see *Industrial Applications*, below. (See *ATOMIC ENERGY: Peacetime Applications*.)

Thorium was identified as an element by J. J. Berzelius in 1828. The element is named after Thor, Scandinavian god of war.

Freshly cut massive thorium is silvery white in colour but turns gray or black on exposure to air. The stability of the surface is a function of the oxide content and surface potential. A cold rolled sheet processed to a high finish remains remarkably stable, retaining a high metallic lustre for years.

The metal may be extruded, rolled, forged, swaged, and spun. Drawing is a difficult operation because of its low tensile strength. Most of the operations with the exception of extruding and spinning may be performed cold. Work hardening is moderate, and annealing is usually *in vacuo* at 800°–1,000° C (1,475°–1,800° F). The major embrittling element is carbon, which dissolves in thorium with resulting lattice expansion. Thorium powder is relatively stable in air, but spontaneous combustion has occurred and the storage of large quantities is hazardous. The solid metal is not readily oxidized in air at high temperatures. High-temperature steam is more effective.

Thorium metal is practically nonreactive to acetic acid (0–50%) and also to sodium hydroxide in all concentrations. It is attacked by hydrochloric acid (0.1–36%) but only slightly by nitric acid in all concentrations, provided traces of fluorides are absent. Boiling water converts the metal to thorium oxide.

## OCCURRENCE AND PRODUCTION

**Mineral Deposits.**—Minerals in which thorium is the major constituent are the silicate thorite,  $\text{ThSiO}_4$ , and the mixed uranium thorium oxide, thorianite (see *THORITE*; *THORIANITE*). A very large number of minerals also contain thorium, but deposits of these minerals are usually too small to be of industrial importance. Thorogummite is an important variety of thorianite, and auelite, pilbarite, hyblite, and enalite are varieties of thorite found in different parts of the world.

The major source of thorium is monazite (*q.v.*), essentially a phosphate of the rare earths [ $(\text{Ce}, \text{La}, \text{Nd})\text{PO}_4$ ]. Important deposits are found in Kerala (formerly the state of Travancore-Cochin) in India, and Brazil. Significant deposits have been found in the Scandinavian peninsula, Ceylon, Tasmania (Australia), the Ural mountains (U.S.S.R.), and Cape of Good Hope, South Africa. U.S. deposits are in Idaho, Colorado, North Carolina, Virginia and Florida. Monazite sands usually contain 2–10% thoria ( $\text{ThO}_2$ ). The poorer ores are concentrated to an oxide content of 5–10% prior to refining.

**Extraction.**—The recovery of thorium compounds, in particular the oxide ( $\text{ThO}_2$ ), from monazite concentrates depends upon the separation of this element from cerium and other rare-earth phosphates and substantial amounts of silica, calcium oxide, and iron oxide.

In some monazites the cerium content ( $\text{CeO}_2$ ) is 40–50% and the phosphorus content ( $\text{P}_2\text{O}_5$ ), 20–25%. The separation is accomplished by a variety of methods, including precipitation after digestion with an acid or base, direct reaction with chlorine, separation by an organic liquid, reduction with calcium, and electrolysis.

**Precipitation.**—Commercial extractive processes in use for many years involve the digestion of pulverized monazite in hot concentrated sulfuric acid to dissolve the thorium and rare earths. If the solution is diluted or partially neutralized with ammonia, thorium phosphate separates, and the ratio of  $\text{ThO}_2$  to rare earths is increased.

For the complete removal of phosphorus and the remaining rare earths several operations have been used. The important ones are sulfate separations, carbonate extractions, oxalate separations, and iodate separations.

The sulfate separation procedure depends upon the low solubility of thorium sulfate,  $\text{Th}(\text{SO}_4)_2 \cdot 8\text{H}_2\text{O}$ , compared with the sulfates of cerium, neodymium, praseodymium, and lanthanum. In carbonate extraction, thorium forms a soluble double carbonate, and cerium precipitates. The precipitation of thorium as the oxalate from dilute acid solutions is commonly used to separate small amounts of the rare earths and some common metals. It is also used as a final step prior to conversion to oxide which is obtained by ignition.

Some monazites yield to sodium hydroxide extraction, with thorium and the rare earths precipitating. It is used as a means of separating thorium from phosphorus.

The precipitation of thorium iodate from strong nitric acid solution affords an excellent separation of thorium from the rare earths and common metals, but it is too expensive for commercial practice.

In spite of the complicated procedures involved in precipitation, thorium oxide of over 99% purity is produced. The major contaminants are small amounts of cerium, rare-earth oxides, silica, calcium, and magnesium. None of these impurities is present in amounts exceeding 0.1%, and many are of the order of 0.04% or less.

**Reaction With Chlorine.**—Production processes have been suggested which involve the extraction of thorium chloride by the direct reaction of the ore, the oxide, or the oxalate with chlorine. Efficiency of chlorination is increased by mixing the materials with carbon. Chlorine gas saturated with sulfur chloride or carbon tetrachloride may also be used. The direct formation of the chloride affords the preparation of a soluble compound of thorium which may be easily purified or if sufficiently pure may be used directly for metal production.

**Extraction by Organic Liquid.**—Processes have been developed for separating thorium from the rare-earth nitrates. Calcium nitrate and nitric acid are added to a solution of the nitrates and thorium nitrate extracted into an immiscible organic liquid, usually tributyl phosphate (TBP). Organic solutions of primary long chain amines are also useful for thorium extraction. The extraction is accomplished by mixing the two fluids by passage in opposite directions through a vertically packed column. The rare earths and other impurities remain in the water phase. The organic phase containing the thorium nitrate is then back-extracted, the thorium nitrate entering the water phase from which the oxide may be recovered by evaporation and ignition. Oxide with a purity of 99.7% has been produced.

**Reduction With Calcium.**—Several processes have been proposed which include reduction of the fluoride ( $\text{ThF}_4$ ) and oxide ( $\text{ThO}_2$ ) with calcium. These reactions are carried out on a large scale in closed metal containers usually referred to as "bombs." The reactants are heated to initiate the reaction. The thorium as a metal powder is recovered by leaching the charge with suitable acids which dissolve the by-products of the reaction. A method of preparation is to add metallic zinc to the charge to form a zinc alloy with the thorium, which fuses. Thorium is recovered by vacuum distillation of the zinc followed by vacuum casting of the thorium. A particular advantage is the elimination of a powder step in the process.

**Electrolytic Methods.**—Electrolysis of thorium compounds such as the chloride ( $\text{ThCl}_4$ ) from alkali metal baths have shown promise of replacing the "bomb" type of reaction. Such processes may be continuous, requiring only the insertion of electrodes with occasional bath replacement. Thorium is deposited on a metal cathode (molybdenum), and the crucible containing the charge

serves as the anode. The deposit upon withdrawal from the bath contains thorium powder plus solidified salts and is recovered by grinding and acid leaching.

Metal of very high purity is obtained by subjecting the primary deposition product to an electrolytic refining operation in which the compressed deposit acts as the anode in a fused salt bath and the thorium is redeposited on a metallic cathode. Lowering occurs in the concentration of many contaminants, including boron, beryllium, copper, chromium, iron, nickel and silicon. The basic principles of the electrolysis and refining operations are shown in fig. 1 and 2.

FIG. 1.—ELECTROLYTIC CELL FOR THORIUM DEPOSITION

used for zirconium production in which iodine and chips of metal are placed in a closed evacuated container that is heated to form thorium iodide vapour. As the vapour comes into contact with a heated filament in the same vessel, thorium of a very high purity is deposited with the liberation of iodine.

Billets for rolling are produced from the powder by standard powder metallurgy (*q.v.*) practice or by direct arc casting. The former practice is to press the powder in steel dies under 20–30 tons per square inch (psi); the resulting green compacts are vacuum sintered. Casting of powder compacts is sometimes made in beryllia crucibles.

Thorium is also cast in a water-cooled copper cup. The powder may be compressed into a rod which acts as a consumable electrode, and the arc is struck between the electrode and solid thorium with the formation of a liquid pool. Melting takes place under a partial pressure of helium or argon gas.

### PHYSICAL AND CHEMICAL PROPERTIES

The physical properties of metallic thorium are strongly affected by small amounts of certain impurities, such as carbon. Melting temperatures, for example, may range from 1,120° to over 1,800° C (about 2,050° to 3,270° F), and boiling points from 3,500° to 4,200° C (6,300° to 7,600° F). Mechanical properties are also affected by methods of production and fabrication, with tensile strength ranging from less than 20,000 to over 60,000 psi. For principal physical constants of the metal see TABLE I.

TABLE I.—Physical Constants (Metallic Thorium)

Atomic number	90
Crystal structure, up to 1,400° C	Face-centred cubic
1,400° C to melting point	Body-centred cubic
Atomic weight	232.038
Unit cell (room temperature)	5.0843 ± 0.0001 Å
Superconductivity transition temperature, °K	1.37
Tensile strength, psi (annealed)	27,000
Heat of fusion, kg-cal/mol	<4.6
Electrical resistivity, microhm/cm (annealed)	15.1
Density, g/cc	11.72
Melting point, °C	1,750
°F	3,182
Boiling point, °C	about 3,500
°F	about 6,332
Young's modulus, psi	10.3 × 10 <sup>6</sup>
Shear modulus, psi	4.1 × 10 <sup>6</sup>
Heat of vaporization, kg-cal/mol	130–145
Periodic table	Actinide series

**Isotopes.**—Thorium occurs in nature as a mixture of radioactive isotopes. The predominant form by far is the very long-lived Th<sup>232</sup>, which is thus the isotope of greatest chemical interest. The other long-lived form of thorium found in nature is Th<sup>230</sup>

(ionium). This isotope is produced by the natural radioactive decay chain that originates in uranium 238, and thus is present in all uranium ores. Other, shorter-lived thorium isotopes arise in nature from the decay of various naturally occurring radioactive

TABLE II.—Longer-Lived Thorium Isotopes

Isotope	Half life	Mode of disintegration	Source
Th <sup>231</sup> (RdAc)	18.2 days	γ	Natural
Th <sup>230</sup> (RdTh)	1.90 years	γ	Natural
Th <sup>229</sup>	7,340 years	γ	U <sup>235</sup> decay
Th <sup>230</sup> (Io)	80,000 years	γ	Natural
Th <sup>231</sup> (UV)	26.6 hours	β <sup>−</sup>	Natural
Th <sup>233</sup>	1.39 × 10 <sup>15</sup>	γ	Natural
Th <sup>234</sup> (UX <sub>1</sub> )	24.10 days	β <sup>−</sup>	Natural

isotopes of actinium and uranium. (See RADIOACTIVITY: Radioactive Series and Isotopes.)

Thorium isotopes have also been produced artificially by various nuclear reactions. Thus, Th<sup>233</sup> is produced by neutron capture in ordinary Th<sup>232</sup>. It decays with a 23.3 min. half-life to form the very important isotope uranium 233.

Th<sup>229</sup> is another synthetic isotope of some importance. It is formed in the decay chain originating in the actinide element neptunium, and as it is reasonably long-lived, can be made to serve as a tracer for ordinary thorium. (See RADIOACTIVITY.)

**General Chemistry.**—Thorium is an electropositive element. It lies between beryllium and magnesium in reducing strength and is more electropositive than zirconium and cerium. In solution, thorium shows only the +4 oxidation state. The standard electrode potential is +1.77 v. As a highly charged ion, Th<sup>4+</sup> undergoes extensive hydrolysis, but to a lesser extent than other +4 ions such as zirconium, cerium, or plutonium. Because of its high charge, the thorium ion is strongly adsorbed from solution by an ion exchanger. Thorium forms complex ions and double salts. Thorium ion is complexed appreciably by nearly all anions. The nitrate is soluble in organic liquids and can be extracted from water solutions by alcohols, ketones, ethers, and esters. This forms the basis for the most advanced practice in the separation and purification of thorium from uranium and fission products in nuclear technology. Thorium compounds are not generally volatile with the exception of the acetylacetonate, Th(C<sub>5</sub>H<sub>7</sub>O<sub>2</sub>)<sub>4</sub>, thorium borohydride, Th(BH<sub>4</sub>)<sub>4</sub>, and a group of organic compounds of the general formula Th(OCR'R''), where R, R' and R'' are radicals. Th(BH<sub>4</sub>)<sub>4</sub> is the most volatile thorium compound known, melting at 204° C but subliming *in vacuo* at considerably lower temperatures.

The dioxide, thoria (ThO<sub>2</sub>), is very refractory. Thoria may be prepared by ignition of the peroxide Th<sub>2</sub>O<sub>7</sub>·4H<sub>2</sub>O, nitrate Th(NO<sub>3</sub>)<sub>4</sub>, hydroxide Th(OH)<sub>4</sub>, sulfate Th(SO<sub>4</sub>)<sub>2</sub>, or of an organic thorium compound. Compounds such as thorium fluoride (ThF<sub>4</sub>) may be converted to oxide by treatment with superheated steam. Thorium peroxide is precipitated from acid solutions with hydrogen peroxide. Ignition yields thorium oxide. The alkalis and ammonia precipitate thorium hydroxide.

The common commercial salt of thorium is the nitrate, which is tetrahydrated. Double nitrates of thorium are known with sodium and potassium and also with some bivalent ions such as magnesium, zinc, cobalt, and manganese.

Hydrogen gas reacts with thorium metal to produce thorium hydrides of the composition ThH<sub>2</sub> and Th<sub>4</sub>H<sub>15</sub>. Thorium hydride is used as a substitute for thorium powder in some applications. A particular advantage is its greater resistance to atmospheric oxidation. Fluorine reacts with thorium hydride or thorium to form thorium fluoride. Thorium fluoride may be separated from solutions by addition of the fluoride ion, but it is hydrated and must be treated with hydrogen fluoride gas to yield the anhydrous fluoride.

Chlorine or hydrogen chloride reacts with thorium hydride or metal to form thorium chloride (ThCl<sub>4</sub>), which sublimes at temperatures in excess of 750° C, *in vacuo*. Bromine or hydrogen bromide converts the hydride or metal to bromide, and a corresponding reaction occurs with iodine. The chlorides, bromides and iodides are soluble in water but hydrolyze. Unstable black

lower halides,  $\text{ThX}_2$  and  $\text{ThX}_3$ , are formed by direct reaction of thorium metal and the appropriate quantity of halogen. Thorium iodate,  $\text{Th}(\text{IO}_3)_4$ , is formed upon addition of an iodate to thorium solutions.

TABLE III.—Physical Properties of Thorium Halides

Compound	Colour	Melting point °C	Boiling point °C
$\text{ThF}_4$	White	1,111	
$\text{ThCl}_4$	White	770	921
$\text{ThBr}_4$	White	679	857
$\text{ThI}_4$	Tan	566	837

Normal thorium sulfide ( $\text{ThS}_2$ ) is purple and may be prepared by the action of hydrogen sulfide on thorium hydride. This sulfide is stable up to  $1,900^\circ\text{C}$ , above which sulfur is evolved and  $\text{Th}_2\text{S}_3$  (brown),  $\text{Th}_7\text{S}_{12}$  (black), or  $\text{ThS}$  (silver) are formed. These compounds resemble metals and may be machined, filed, and polished.

Thorium sulfate,  $\text{Th}(\text{SO}_4)_2$ , crystallizes from aqueous solutions in several hydrates depending upon temperatures. Heating *in vacuo* produces the normal salt and ignition yields the oxide. Double sulfates are also known. Chromates, phosphates, and molybdates may be precipitated from water solutions.

Thorium carbides, both  $\text{ThC}$  and  $\text{ThC}_2$ , have been identified and are prepared by heating the metal or oxide with carbon at high temperatures. These react with water to yield hydrocarbons. Thorium carbonate,  $\text{ThCO}_3$ , is difficult to prepare from solution, but double carbonates are easily prepared.

Thorium salts with organic acids are usually insoluble. The formate and the acetate are exceptions. Examples of insoluble salts are the oxalate, picrolonate, sebacate, and 8-hydroxy quinolate.

Two thorium nitrides have been identified,  $\text{ThN}$  and  $\text{Th}_2\text{N}_3$ . The nitrides are unstable at high temperatures in the presence of water vapour with the elimination of ammonia. The mononitride melts at about  $2,630^\circ\text{C}$  without decomposition, whereas the sesquinitride loses nitrogen in a vacuum of  $1,500^\circ\text{C}$ . Two phosphides,  $\text{ThP}$  and  $\text{Th}_3\text{P}_4$  also exist.

The silicides  $\text{Th}_3\text{Si}_2$ ,  $\text{ThSi}$ ,  $\text{ThSi}_2$ , and  $\text{Th}_2\text{Si}_3$  are formed from the elements at  $1,000^\circ$  to  $1,700^\circ\text{C}$ . The very refractory  $\text{ThB}_4$  melts above  $2,500^\circ\text{C}$ , whereas the hexaboride  $\text{ThB}_6$  melts at  $2,195^\circ\text{C}$ . Both compounds are formed by the high temperature reaction of thorium and boron.

## USES

**Industrial Applications.**—The earliest use of thorium oxide was in the incandescent gas-mantle industry. In 1885 Carl Auer von Welsbach patented a mixture of 99% thoria and 1% ceria which was impregnated into a combustible fabric (cotton or ramie) as nitrates. Ignition of the Welsbach mantle resulted in oxide formation which when heated in a gas flame emitted white light for illumination. The use of gas mantles declined sharply after the introduction of electrical lighting. (See *LIGHTING: Historical Development*.)

Thorium oxide is used in the electrical lighting industry for controlling the grain size of tungsten filaments used in lamps as a radiant source of energy. Pure tungsten is unsatisfactory because the metallic grains continue to grow when the filament is heated, causing some grains to slip along grain boundaries. The addition of 0.8–1.0%  $\text{ThO}_2$  to the tungsten produces a stable structure. Such filaments also exhibit increased vibrational strength.

Thorium oxide-metal systems have been used for years in electronics as a source of primary electron emission. The thorium oxide content is usually 1–2%. So-called cermets which are oxide-metal compositions, in particular Mo- $\text{ThO}_2$  have been used as an emission source. A desirable property of these latter combinations is that the electrical resistance may be easily controlled by changes in composition. (See *THERMIONICS: Reduction in Electron Affinity*.)

The oxide has gained wide use as a component of electrodes for arc welding. The addition of 1–2%  $\text{ThO}_2$  to tungsten results

in improvement in arc stability over that exhibited by pure tungsten. A practice embodying the same principle is the incorporation of the oxide in tungsten electrodes used in arc-casting metals. The addition of thorium oxide lowers the work function of the metal, that is, the ease with which electrons may be emitted thermionically.

Thorium oxide crucibles are used to a limited extent for melting some of the common and transition metals. Its use is quite selective. It is not satisfactory for melting oxygen-sensitive metals such as zirconium and titanium. Its relatively high cost and poor resistance to thermal shock limit its use to operations where it shows marked superiority over other competing ceramics.

Thorium sulfide crucibles have been investigated and show promise up to  $1,800^\circ\text{C}$ . The monosulfide ( $\text{ThS}$ ) is the more stable compound.

Thorium oxide, as well as the oxides of beryllium, zirconium, and aluminum, is of importance as a current-carrying compound in high-temperature furnace design and insulation. These oxides have negative temperature characteristics, and the limiting factor in their use is excessive conductivity. Thorium oxide compositions have been used experimentally where the resistor element is composed of 85–95%  $\text{ThO}_2$  and 5–15% yttrium oxide ( $\text{Y}_2\text{O}_3$ ) or lanthanum oxide ( $\text{La}_2\text{O}_3$ ).

Thorium oxide is an efficient catalyst in reactions involving oxidation, hydrogenation and cracking of hydrocarbons. In many cases it is used as a mixture with aluminum oxide.

A very important alloy application of thorium is its addition to magnesium and magnesium alloys for improving their high-temperature strength. The addition of 1–5% thorium to these alloys permits their use in temperatures up to  $340^\circ\text{C}$  (about  $650^\circ\text{F}$ ), in compressor housings. The addition of small amounts of thorium increases both the strength and ductility of magnesium rolled sheet, a use consuming considerable quantities of the metal.

Thorium metal has been used as a deoxidant in molybdenum. It is also used in electronic tubes and lamps for lowering the starting voltages and maintaining stability in such lamps over their useful life.

Thorium is used in photoelectric cells for measurement of a wide band of the ultraviolet spectrum. The response of commercial tubes extends from 2,000–3,750 Å.

**Nuclear Applications.**—Thorium 232 does not undergo nuclear fission with slow neutrons, and so it cannot be used directly as a nuclear reactor fuel. It can, however, be converted to the fissile isotope uranium 233:

When naturally occurring thorium is irradiated with slow neutrons, it is transmuted to a uranium isotope that can undergo fission with slow neutrons to yield enormous quantities of energy. The fission of the usual fuel in a nuclear reactor yields more neutrons than are needed to sustain the chain reaction, and the excess neutrons can be caused to be captured by  $\text{Th}^{232}$ . Thorium is thus made to "breed" additional fissile nuclear fuel, with the paradoxical result that more fissionable fuel is generated by "breeding" than is consumed in the course of nuclear power production. (See also *URANIUM; ATOMIC ENERGY: Peacetime Applications*.)

The possibility of converting thorium to fissile uranium 233 in breeder reactors and by so doing tremendously increasing world resources of nuclear energy is the most important potential use for thorium.

See also *ATOMIC ENERGY; NUCLEAR ENGINEERING*; see also references under "Thorium" in the Index.

**THORNABY-ON-TEES** a municipal borough in the North Riding of Yorkshire, England, 3 mi. S.W. of Middlesbrough by road, in the Middlesbrough West parliamentary division. Pop. (1961) 22,793. Area 3 sq.mi. It lies on the Tees river, opposite Stockton-on-Tees, with which it is connected by a bridge. In the 8th century the Danes called it Thormodby; in Domesday Book it appears as Tormozby. The parish church on the village green is Norman. Thornaby's industrial development dates from the 19th century. It was incorporated as a separate borough in 1892. The population is employed chiefly in bridge building, heavy engineering, foundries, wire ropemaking, shipbreaking, flour milling, the production of sugar and preserves.

**THORNDIKE, EDWARD LEE** (1874–1949), U.S. psychologist, strongly influenced education toward social utility through his experimentally derived theories of learning. He was born at Williamsburg, Mass., Aug. 31, 1874. His career, save for one year at Western Reserve University, Cleveland, O., was spent at Teachers College, Columbia University. An unusually creative and productive scholar, he was author or coauthor of more than 500 books and articles. His influence on psychological and educational thinking has been worldwide.

Thorndike's pioneer work on the intelligence of laboratory animals in the 1890s established a trend in psychology that still continues. His laws of learning came to hold a central place in learning theory.

Thorndike was responsible for many of the early applications of psychology to such fields as arithmetic, algebra, reading, handwriting, and language. Other major contributions include works on the theory of psychological tests and compilations of the words occurring most frequently in English reading matter.

Best known is his three-volume work *Educational Psychology* (1913–14). Additional works of special interest treat the behaviour of monkeys; prediction of vocational success; wants, interests, and attitudes; and principles of education. Thorndike died at Montrose, N.Y., on Aug. 9, 1949.

**THORNDIKE, DAME SYBIL** (1882– ), British actress of remarkable versatility, was born at Gainsborough, Lincolnshire, on Oct. 24, 1882. She was educated at the high school in Rochester, where her father was a canon of the cathedral. She prepared for the stage at Ben Greet's Academy and toured the U.S. with his Shakespearean company in 1904–07. She married the actor-director (Sir) Lewis Casson in 1908. After performing with Miss A. E. Horniman's company in Manchester (1908–09 and 1911–13), she joined the Old Vic Company in London (1914–18) and helped to establish not only the theatre's name as a home of Shakespeare but also her own as the most promising English tragic actress of the day.

Having set the seal on this reputation in 1919–20 with performances as Hecuba in *The Trojan Women* and as Medea, she went on to prove her versatility in a multiplicity of parts, modern as well as classical, comic as well as tragic. In 1924 she created the name part in Shaw's *Saint Joan*; and though many admired actresses followed her, none realized the character more completely.

Her superb health and vigour did not desert her as she grew older, and she was able to tour the world in exacting classical parts at an age when many of her contemporaries had been content to retire. Also, in her 60s, she broke new ground, giving, in such plays as *The Linden Tree* (1947), *The Foolish Gentlewoman* (1949), *Treasure Hunt* (1949), *Waters of the Moon* (1951), and *A Day By The Sea* (1953), a whole gallery of portraits of elderly women having in common nothing but the meticulous and humorous observation which the actress had brought to their creation. She was created a dame of the British Empire in 1931.

(W. A. DN.)

**THORNHILL, SIR JAMES** (1675–1734), English painter, the first to excel in historical painting, whose style was in the Italian Baroque tradition, was born at Melcombe Regis, Dorset. He became the history painter and sergeant painter to George I and George II, master of the Painters' Company in 1720, fellow of the

Royal Society in 1723, member of Parliament from 1722 to 1734, and was knighted in 1720. He was one of the original directors of Kneller's Academy of Painting, and when this closed, and he had failed to establish a "royal academy," he opened his own drawing school, which also proved unsuccessful. Thornhill died at Thornhill, Dorset, on May 13, 1734.

The eight scenes in the dome of St. Paul's Cathedral (1715–19) and the allegories in the Painted Hall, Greenwich Hospital (1708–27), are his two most considerable works. His paintings were largely executed on the ceilings and stairs of such country houses and palaces as Hampton Court, Blenheim, and Chatsworth. Among Thornhill's few canvases are the altarpiece for St. Mary's Parish Church, Weymouth, and a group portrait of the members of the House of Commons in which he was assisted by William Hogarth, his son-in-law. Thornhill also did portraits (his sitters including Isaac Newton and Richard Steele), book illustrations, theatre scenery, and the rose window of the north transept of Westminster Abbey (1721). (Wm. O.; X.)

**THORNTON, WILLIAM** (1759–1828), British-U.S. architect, inventor, and public official who created the original design for the Capitol at Washington, D.C., was born May 20, 1759, at Tortola, V.I. He studied medicine at the University of Edinburgh (1781–84) and received his M.D. from Aberdeen University (1784). After travel on the continent he returned to Tortola and went to the United States in 1787. In the following year he became a United States citizen and settled in Philadelphia. The Library Company of Philadelphia promoted a competition (1789) for its new building that Thornton won without formally having studied architecture. As inventors he and John Fitch (q.v.) early experimented with paddle steamboats.

From 1790–92 he was again at Tortola, where he first heard of the important competition for the Capitol at Washington. He submitted designs that were received months after the competition closed; yet the judges, not satisfied with those previously submitted, selected Thornton's. His revised Georgian design of 1795 was executed as the exterior of the north and south wings adjacent to the central rotunda, though B. H. Latrobe (q.v.) completely redesigned the interiors. From 1794–1802 Thornton was a commissioner of the city of Washington. He designed the Octagon, Washington (1798–1800), a residence for John Tayloe. From 1802–28 he served as first superintendent of the Patent Office. He died in Washington on March 28, 1828, and was buried in the congressional cemetery. (P. F. N.)

**THORNYCROFT, SIR (WILLIAM) HAMO** (1850–1925), English sculptor, executed many public monuments, including those to Gen. Charles George Gordon (1888, formerly Trafalgar Square), Oliver Cromwell (1899, Westminster), Dean John Colet (1902, St. Paul's School, Hammersmith), William Gladstone (1905, Strand), and the architect Richard Norman Shaw (bas-relief, 1914, New Scotland Yard). He was born in London on March 9, 1850, and studied under his father, Thomas Thornycroft, at the British Museum, at the Royal Academy Schools and in Italy, where he was particularly interested in Michelangelo. In 1872 he contributed the figures of Shakespeare, Fame and Comedy to the Poets' Fountain, Park Lane (later removed), designed by his father. His independent success began with "Artemis" (exhibited 1880), and in 1881 he showed the bronze "Teucer" (Tate Gallery, London) at the Royal Academy, of which he was then elected associate. His style, at first an enlivened classicism, was affected in the mid-1880s (in "The Mower," 1884, Walker Art Gallery, Liverpool; "A Sower," 1886) by J. F. Millet's peasant realism and later (e.g., "The Kiss," 1916, Tate Gallery) was influenced slightly by Auguste Rodin. Thornycroft was elected royal academician in 1888 and knighted in 1917.

Thornycroft died at Oxford on Dec. 18, 1925. He was the brother of Sir John Isaac Thornycroft (q.v.).

**THORNYCROFT, SIR JOHN ISAAC** (1843–1928), British naval architect and engineer who was responsible for the introduction of special designs of ships' hulls and improvements in machinery was born in Rome on Feb. 1, 1843. He was sent by his father, Thomas Thornycroft, a sculptor, who was also an amateur engineer, to Glasgow university, after which he

worked for a short time in John Elder and Palmer's shipyards. In 1866 he started his own launch-building and engineering works at Chiswick, London. Gaining a high reputation for his boats, he was given the order for H.M.S. "Lightning," the first torpedo boat of the Royal Navy. Later he took into partnership his brother-in-law, John Donaldson. Thornycroft took a leading part in introducing water tube boilers into the British and into other navies and was granted a number of patents, including one of the earliest for ship stabilizers. He served as a member of Lord Fisher's committee, which produced the design for the battleship "Dreadnought" and introduced oil fuel for the Royal Navy. He was knighted in 1902 and died on June 28, 1928, at Bembridge, Isle of Wight. (J. E. Tr.)

**THOROUGH BASS**, in music, a system of accompaniment (*q.v.*) customary during the 17th and 18th centuries: the bass line is written out all "Thorough" (*i.e.*, through) the composition, but its harmonization is left to the accompanist to provide more or less impromptu. Usually, though not invariably, he is kept generally informed as to the harmony resulting from the melodic part or parts which he is accompanying, so as not to conflict with it in his own harmonization. This information is conveyed by figures added to the bass line, which is then more specifically described as figured bass.

The accompanist is said to "realize" the bass. He may do this impromptu, *i.e.*, reading it strictly at sight in course of performance: a very skilled achievement to which not many modern performers are trained. But it was always customary to look through the music in advance if opportunity occurred. This allows the performer to improve on his first thoughts, and, in music suited to an elaborate accompaniment, is normally the best course. It hardly matters whether his preparations are memorized or written out in whole or part, but it does matter that the result shall sound free, flexible and spontaneous, as if it had been improvised. Modern editors who provide printed realizations usually bear this in mind, keeping their parts on the light side.

The information conveyed by the figures is never complete and is often so sketchy, not to say inaccurate, that the performer, when no preparation has been possible, has to rely on his own grasp of where the music is going. This came more easily to a contemporary performer than it does to present-day musicians, but the faculty can be cultivated. Indeed it is one of the most enjoyable parlour games. According to J. F. Daube's *General-Bass* (1756), the style of improvised accompaniment was brought to its height by J. S. Bach: "He knew how to introduce a point of imitation so ingeniously in either right or left hand and how to bring in so unexpected a counter-theme, that the listener would have sworn that it had all been composed in that form with the most careful preparation . . ." The true reason for thorough bass is the freshness of the invention. Thorough bass was thus not merely a convenient shorthand for saving the composer's time; it was a means of giving zest to the accompaniment by inviting the performer to draw on his capacity for spontaneous enjoyment.

The figures themselves are numerals set one above the other to indicate the intervals, as counted up from the bass note, of the harmonies required. In realizing these intervals, the performer can invert them in any order of notes; *i.e.*, he can manipulate the spacing of the chord, though he will not normally go above the solo part for long at a time, if at all. The figures are kept to the minimum necessary to determine the harmony by indicating its most characteristic intervals, the remainder of the chord being taken as understood. Necessary accidentals are shown. Only the main harmonies, and not the passing harmonies, are normally shown. There is great scope for varying and enriching the indicated harmony by introducing passing notes, especially accented passing notes. The same recourse is invaluable for contriving an interesting and convincing melodic outline to the accompaniment.

The elaboration given to the realization will vary from the simplest harmonization in plain part-writing to an exploitation of all the harmonic and contrapuntal possibilities. Four-part harmony is standard, though the nature of the music to be accompanied sometimes requires only three or two parts and occasionally the

unharmonized bass line. Alternatively, a "full accompaniment" requires as many notes to each hand as the fingers can accommodate and in such realizations all rules forbidding consecutive fifths, etc., may be waived except as between the two outside (bottom and top) parts.

Good figured-bass accompaniment, taking into account not only the character of the piece but, as C. P. E. Bach specified, the remaining performers, the soloist, the auditorium and the audience, thus made almost as heavy a demand on the performer's judgment as on his imagination.

**THORPE, JIM** (JAMES FRANCIS THORPE) (1888–1953), U.S. athlete, considered one of the greatest all-around athletes of all time, was born May 28, 1888, near Prague, Okla., of American Indian descent. A star in both college and professional football, he was twice named halfback on Walter Camp's All-America teams (1911, 1912); in 1912 he scored 25 touchdowns and 198 points for Carlisle (Pa.) Institute.

Standing 6 ft. tall and weighing 190 lb., Thorpe was a standout in the 1912 Olympic Games at Stockholm, where he won the pentathlon and decathlon. Later, however, when it was discovered that he had played semiprofessional baseball in the summer of 1911, his gold medals and trophy were taken from him and his Olympic records erased from the books.

Signed by John J. McGraw of the New York Giants for \$4,500 in 1913, Thorpe spent most of the time on the bench. He finished his six-year major-league baseball career in 1919 with the Boston Braves, where he played in 60 games and hit .327. He died in Lomita, Calif., March 28, 1953. See also FOOTBALL: U.S. Football: U.S. Professional Football. (J. D. McC.)

**THORPE (THORP), THOMAS BANGS** (1815–1878), U.S. humorist, was one of the most effective portrayals of frontier life and character before Mark Twain; he is the author of "The Big Bear of Arkansas," a tall tale so outstanding that some historians have named certain southwestern contemporaries of Thorpe the Big Bear School of Humorists. Born at Westfield, Mass., on March 1, 1815, and educated in New York schools, Thorpe studied painting under John Quidor and at the age of 18 exhibited his "Ichabod Crane" at the American Academy of Fine Arts, New York City. In 1836, after two years' study at Wesleyan University, Middletown, Conn., he moved to Louisiana. An active Union Whig, he published successively five newspapers, chiefly in New Orleans and Baton Rouge. It was during this period that Thorpe wrote "The Big Bear of Arkansas," published in 1841 in the New York magazine *Spirit of the Times*.

Following a political defeat, Thorpe moved in 1854 to New York City and published his finest sketches as *The Hive of the Bee Hunter*. During the Civil War he saw service in New Orleans; afterward he returned to New York and spent his remaining years painting, working at the customhouse, and writing for *Harper's*, *Appleton's*, and other journals. He died at New York, on Sept. 20, 1878.

Thorpe's painting and writing show the influence of Washington Irving and of sporting literature, a love of romantic scenery, and a continuing attempt to define the distinctively American character, which, he believed, the western frontier was producing.

See Walter Blair, *Native American Humor* (1937); Milton Rickels, "A Bibliography of the Writings of Thomas Bangs Thorpe," *American Literature*, 29:171–179 (1957). (M. H. R.)

**THORPE, SIR THOMAS EDWARD** (1845–1925), British chemist, was perhaps best known for his direction of the British government laboratories and as a brilliant lecturer and writer. He was born at Harpurhey, Manchester, on Dec. 8, 1845, and studied at Owens College, Manchester, and at Heidelberg, where he obtained his doctorate (1869). In 1870 he became professor of chemistry at Andersonian College, Glasgow, and four years later at the Yorkshire College, Leeds. In 1885 he obtained the chair at the Normal School of Science (later the Imperial College of Science), London, and remained there until appointed director of

the government laboratories in 1894. On his retirement, he returned to the Imperial College (1909–12). He was elected to the Royal Society in 1876, was made a companion of the Bath in 1900, and was knighted in 1909. He died at Salcombe, South Devon, on Feb. 23, 1925.

Thorpe brought out, with the cooperation of a number of specialists, the *Dictionary of Applied Chemistry* (1890). He was also the author of *Essays in Historical Chemistry* (1894) and a biography of Joseph Priestley (1906). His contributions to chemical knowledge included an accurate series of measurements of the specific volumes of chemical substances of related composition. With A. E. H. Tutton he studied the oxides of phosphorus (1886 and following) and discovered phosphorus tetroxide. From 1884 to 1886 Thorpe made a long series of measurements (with J. W. Rodger) of the viscosities of organic substances and attempted to correlate fluidity and composition. With Sir Arthur Rücker, he carried out (1884–88) a magnetic survey of the British Isles.

**THORVALDSEN** (THORWALDSEN), **BERTTEL** (1768 or 1770–1844), Danish sculptor and prominent neoclassicist, who spent most of his working life in Rome, was the son of an Icelandic woodcarver who had settled in Denmark. He was born in Copenhagen either on Nov. 19, 1770 (his own statement), or Nov. 13, 1768 (subsequent theory), and studied at the Copenhagen Academy, where he won a traveling scholarship to Rome. In Rome the prevailing enthusiasm for classical sculpture fired his imagination to such an extent that he subsequently celebrated the date of his arrival in Rome in 1797 as his "Roman birthday." The success of Thorvaldsen's model for a statue of Jason (1803), which was commissioned in marble by the English author and connoisseur Thomas Hope, attracted the attention of Canova, and launched Thorvaldsen on one of the most spectacularly successful careers of the 19th century. When he made his first return visit to Copenhagen in 1819, his progress through Europe, visiting Berlin, Warsaw, and Vienna, was like a triumphal procession. His return in 1838, when he eventually decided to settle in his native city, was regarded as a national event in Danish history. A large portion of his fortune went to the endowment of a neoclassical museum in Copenhagen (begun in 1839), which was designed to house his collection of works of art and the models for all his sculptures. He died in Copenhagen on March 24, 1844, and was buried, by his own wish, in the courtyard of the museum that bears his name. Most of Thorvaldsen's most characteristic sculptures are reinterpretations of the figures or themes of classical antiquity, and the Alexander frieze of 1812 in the Palazzo Quirinale, Rome, modeled in only three months in anticipation of a visit by Napoleon, is an example of the feverish energy with which he could at times apply himself to work. Religious sculptures (for which his style was not particularly well suited) include the colossal series of statues of Christ and the 12 apostles (completed 1838) in the Vor Frue Kirke in Copenhagen. He also made numerous portrait busts of his distinguished contemporaries. In the general re-evaluation of Neoclassicism Thorvaldsen's reputation outside Denmark has declined, and works once regarded as the perfect reincarnation of the antique now tend to seem rather cold and dry.

See P. O. Rave, *Thorvaldsen* (1947); S. Schultz, *Thorvaldsens Museum: Official Guide* (1953).

**THOTH**, Greek form of the name of the Egyptian god DJ-HOWTEY, whose cult was centred in the town of Khmunu (Lat. Hermopolis Magna [q.v.]; mod. Al Ashmunayn) in Upper Egypt. At first he was probably the moon-god; as such, he was called "reckoner of time," and his name was given to the first month of the Egyptian year. In consequence he became the god of reckoning and of learning in general and was held to be the inventor of writing, the founder of social order, the creator of languages, the scribe, interpreter, and adviser of the gods, and the representative of the sun-god, Re, on earth. He was also the patron of scribes and officials. Thoth played an important part in the myth of Osiris (q.v.), protecting Isis during her pregnancy and healing the injury inflicted on her son Horus by Osiris' adversary, the god Setekh. Thoth weighed the hearts of the deceased at their judgment and reported the result to the presiding god, Osiris, and his fellow judges.

Thoth's sacred animals, for reasons which are not quite clear, were the ibis (*Threskiornis aethiopica*) and the baboon (*Papio hamadryas*); numerous mummified bodies of these two animals were found in cemeteries near Hermopolis and Thebes. Thoth himself was sometimes represented as an ibis or as a baboon, but more usually in human form with an ibis' head. The Greeks identified Thoth with their god Hermes and traced back to "Thoth, the thrice great" (Hermes Trismegistos; q.v.) the authorship of powerful magical books.

See P. Boylan, *Thoth, the Hermes of Egypt* (1922). (J. Cy.)

**THOU** (THUANUS), **JACQUES AUGUSTE DE** (1553–1617), French statesman, bibliophile, and historiographer, whose detached approach to the events of his own period made him a pioneer in scientific approaches in history.

Born in Paris on Oct. 8, 1553, of a family noted for its statesmen and scholars, he studied law at Orléans and Bourges, where he met François Hotman (q.v.), and at Valence, where he was a pupil of Jacques Cujas (q.v.) and a friend of J. J. Scaliger. However, he had first been intended for the church, and on the appointment of his uncle Nicolas to the episcopate of Chartres, he succeeded him as a canon of Notre Dame (Paris). As a councillor of state he faithfully served both Henry III and Henry IV, becoming director of the royal library in 1593. On succeeding his uncle Augustin as a president of the Paris *parlement* in 1595, he used his new authority in the interests of religious peace, negotiating the Edict of Nantes (1598) with the Protestants, while in the name of Gallicanism opposing recognition of the Council of Trent (q.v.). This attitude exposed him to the animosity of both the Holy League (q.v.) and the Holy See, which increased its persecution when the first edition of his history appeared in 1604. His minor works include a poem on falconry, *De re accipitraria* (1584), and some *Poemata sacra* (1599). After the death of Henry IV (1610), the queen regent, Marie de Médicis, refused him the appointment of premier president of the *parlement*, appointing him instead a member of the *conseil de finances*. He helped to negotiate the treaties of Sainte-Menehould (1614) and Loudun (1616). He died in Paris on May 7, 1617.

The writing of his history was the main activity of De Thou's life. The materials for it were drawn from his rich library, which had originated in 1573 when he was at Notre Dame and which was established in 1587 in the Rue des Poitevins; and he was helped in his preparations by Pierre Dupuy (1582–1651) and his brother Jacques (1586–1656), the two illustrious scholars and librarians who later also collected some of his minor works (see *Bibliography*). De Thou's object in his history was to produce a purely "scientific" and unbiased work, and for this reason he wrote it in Latin, entitling it *Historia sui temporis*. His starting point he defined as "the last years of the reign of Francis I," that is, about 1543. Actually, he begins with a careful, though general, survey of the early 16th century, and the history therefore covers the whole of the 16th century. The first 18 books (embracing the period up to 1560) appeared in 1604, when they were immediately attacked by those whom the author himself called "les envieux et les factieux" ("the invidious and the dissentious"). The second part (dealing with the first wars of religion, 1560–72) was put on the Index. When the third part (to 1574) and the fourth (to 1584) appeared in 1607–08 they caused a similar outcry, in spite of De Thou's efforts to remain impartial. In answer to his detractors he wrote a series of memoranda (translated into French as *Mémoires de la vie de Jacques Auguste de Thou*, 1711), which are a useful complement to the *Historia*.

The first complete edition of De Thou's *Historia*, including the fifth part (to 1607), was published in 1620 by Pierre Dupuy and Nicolas Rigault. This comprised 138 books, to which the *Commentariorum de vita sua libri sex* (six volumes of memoirs) were appended in 1625. In 1733 a critical Latin edition in 7 volumes was published in London by Samuel Buckley, the material for which had been collected and prepared in France by Thomas Carte. Carte's research confirmed that de Thou's *Historia* was a model of exact scholarship, drawn from reliable sources. In 1734 the standard French translation, entitled *Histoire universelle de Jacques-Auguste de Thou, depuis 1543 jusqu'en 1607*, was published

in 16 volumes by the abbé Desfontaines and other scholars.

**THOUGHT, LAWS OF.** Traditionally, special importance has been attached to three of the simplest laws of logic, the *law of identity*, the *law of contradiction*, and the *law of excluded middle* (or *tertium non datur*). These were called the "laws of thought," a name which may conveniently be retained even by those who do not accept the implications which the name suggests. (For "thinking" as studied in psychology, see **THINKING AND PROBLEM SOLVING**.)

As examples of axioms, or indemonstrable principles (see **AXIOM**), Aristotle cites that, of two contradictories, one must be true, and that it is impossible for anything both to be and not to be. These are the principles which were afterward known as the laws of excluded middle and of contradiction respectively. They occur in Aristotle also in other forms, which are regarded as being expressions of the same laws; e.g., that there is no middle ground between contradictories, and that it is impossible for anything both to be predicated and not to be predicated of the same thing in the same sense. Aristotle partly exempted future contingents from the law of excluded middle, holding that it is not (now) either true or false that there will be a naval battle tomorrow, but that it is (now) true that either there will be a naval battle tomorrow or not; against this, Chrysippus (see **LOGIC, HISTORY OF**) maintained that all propositions, even about the future, are either true or false.

The law of identity has usually been stated (for example by Leibniz) as: A is A. Stated in ordinary language, particular cases of the law would then be such things as: gold is gold, men are men, love is love, etc.

To render the three laws in modern logical notation (see **LOGIC: The Propositional Calculus**), the best choices would seem to be:  $F(x) \supset F(x)$  (law of identity),  $\sim p \wedge p$  (law of contradiction),  $p \vee \sim p$  (law of excluded middle). However, the law of identity is also often given as  $(x) x = x$ , a form which differs from the other (on the basis of the definition of = in the article **LOGIC**) only by the insertion of a quantifier.

The three laws may also be understood in a semantical sense (see **SEMANTICS IN LOGIC**), the traditional statements of them generally not making a sharp distinction between such metatheoretic principles and principles which are rather to be expressed in the notation of propositional calculus or functional calculus. Thus the law of identity would be that a term must preserve the same denotations in all its occurrences, at least throughout any one context; the law of contradiction, that a sentence and its negation, S and  $\sim S$ , are not both true; the law of excluded middle, that either S or  $\sim S$  is true. In this interpretation the "laws of thought" are to be regarded as being about a particular language—or else as general principles of sound notation, demands which any acceptable language or system of notation must satisfy.

The doctrine that the laws of thought—or even only the laws of identity and contradiction—are a sufficient foundation for the whole of logic, or that all other principles of logic are mere elaborations of them, is traceable to Leibniz. Leibniz left a few actual examples of demonstrations of principles of logic and mathematics from only these laws, but all are quite minor in character and moreover involve tacit use of at least syllogistic inference in addition to the laws of thought. It would seem that Leibniz intended originally to express only a hope or an expectation. But later he was more incautious, writing, for instance, in the second letter to Samuel Clarke: "The great foundation of mathematics is the principle of contradiction, or identity, that is, that a proposition cannot be true and false at the same time; and that therefore A is A, and cannot be not A. This single principle is sufficient to all demonstrate every part of arithmetic and geometry, that is, all mathematical principles."

Leibniz's successors applied the doctrine mainly to logic as distinguished from mathematics, but at the same time elevated it into an assertion of established fact. In this form it was common especially among traditional logicians of the 19th century. And though the doctrine appears already in the *Vernunftlehre* (1756) of H. S. Reimarus, its widespread adoption is perhaps due to Kant's characterization of an analytic judgment (see **LOGIC, HISTORY OF**) as one for recognition of whose truth the law of contradiction suffices.

It is difficult to give this doctrine a precise meaning in such a way as to make it tenable. For example it is not true that the three laws, say in the forms  $F(x) \supset F(x)$ ,  $\sim p \wedge p$ ,  $p \vee \sim p$ , are a sufficient set of axioms for logic, or even for the most elementary branch of logic, the propositional calculus, or for the traditional theory of the categorical syllogism.

**Criticisms and Rejections of the Laws of Thought.**—The law of excluded middle and some related laws of propositional calculus and functional calculus of first order are rejected by L. E. J. Brouwer and the school of mathematical intuitionism (see **LOGIC; MATHEMATICS, FOUNDATIONS OF**), not in the sense that the negation of the law is asserted, but in the sense that use of the law is not admitted as a valid method of mathematical proof in cases in which all members of an infinite class are involved. For example, Brouwer would not accept the disjunction that either there occur ten consecutive 7's somewhere in the decimal expansion of the number  $\pi$  or else not (since there is no proof known of either alternative), but he would accept that there occur ten consecutive 7's somewhere in the first  $10^{100}$  digits of the decimal expansion of  $\pi$  or else not (since this could in principle be settled by carrying out the computation of the decimal expansion to the required point).

On the basis of Aristotle's doctrine of future contingents, but not without some modification of it, Jan Łukasiewicz was led in 1920 to formulate a propositional calculus which has a third truth-value (for future contingents) in addition to the usual two, and in which the laws of contradiction and excluded middle alike fail. Propositional calculi with  $n$  truth-values,  $n \geq 3$ , were published independently by E. L. Post in 1921 and by Łukasiewicz in 1930. Corresponding many-valued functional calculi of first order were formulated still later by other writers.

Other criticisms or rejections of one or more of the laws of thought—e.g., by Epicurus (*q.v.*), by Hegel (*q.v.*), by Alfred Korzybski (see **SEMANTICS, GENERAL**)—are in a different category from those of Brouwer and Łukasiewicz, as they offer no precise formulation of a usable logic in which these laws fail or are modified.

**THOUSAND AND ONE NIGHTS** (Arabic, ALF LAYLA WA LAYLA), popularly known as the *Arabian Nights*, a collection of Arabic short stories of uncertain date and authorship. With the possible exception of the Koran, no other work of Arabic literature has been better-known or more influential in the west: indeed, certain stories, such as those about Aladdin, Ali Baba, and Sindbad the Sailor (*q.v.*), have almost become part of the folklore of western Europe. The stories are grouped round a central situation or frame story, in a manner familiar in medieval European literature as, for instance, in Chaucer's *Canterbury Tales* and Boccaccio's *Decameron*. The scene is in central Asia or, as the text puts it, "in the islands, or peninsulæ, of India and China." King Shahryar discovers that his wife has been regularly unfaithful to him during his absences from the palace. Killing her, and the other guilty parties, he is filled with a loathing of all woman-kind. Henceforward he marries, and kills, a new wife every day. Soon no further candidates can be found for the royal hand. The vizier, or prime minister, has two daughters, Shahrazad, the elder,

and Dunyazad. Shahrazad insists that her father give her in marriage to the king, having worked out a scheme whereby she can save both herself and her people. Each evening she tells a story to her sister and the king, but does not finish it, promising to do so on the following night, if she survives. The stories are so entertaining, and the king is so eager to hear how each one ends that he puts off the execution of Shahrazad from day to day and ultimately gives up his cruel plan altogether.

**Texts and Translations.**—Antoine Galland (1646–1715; *q.v.*) produced not only the first translation, but also the first printed edition of the *Nights*. He traveled in the near east first in the French diplomatic service, then as a collector of objects for museums. Returning to France, he made a French translation of the *Nights* from a Syrian manuscript in four volumes. This translation, *Les Mille et Une Nuits, contes arabes traduits en français*, was published in 10 volumes between 1704 and 1712. Volumes xi and xii appeared after his death, in 1717. The later volumes contained many stories from other sources; and there is really no “canonical” text of the *Nights*, in respect to either the stories included or the actual wording of them. Galland translated freely, molding the stories into a form acceptable to Europeans of his day. But he was a born storyteller and his work enjoyed enormous popularity. For over a century it was the standard European version, and parts of it have even been translated back into Arabic.

The Arabic text was first published in Calcutta in an incomplete form in two volumes (1814–18); and again in four volumes (1839–42). However, it was the Egyptian recension which was the basis of 19th–20th century European translations. The first Bulaq (Cairo) edition dates from 1835, and there have been several Cairo editions since. The text was also printed in Breslau (1825–43) as *Tausend und eine Nacht, Arabisch. Nach einer Handschrift von Tunis*, edited by Maximilian Habicht.

During the 19th century, there were several European translations of varying degrees of accuracy and fullness. The question of expurgation troubled some translators, as certain stories in the original are certainly not for juvenile reading. The translation (1838–40) of E. W. Lane (*q.v.*) is incomplete, but has useful notes. John Payne's, in nine volumes, appeared during 1882–84. There were three supplementary volumes in 1884 and a 13th volume in 1889. The most famous English translation is that of Sir Richard Burton (*q.v.*), which is based on Payne's, from which it sometimes quotes passages verbatim. It was published in ten volumes (1885) with six supplementary volumes (1886–88). It has been reprinted since, both in full and in a shortened form. Lady Burton's edition (1886–88) was ruthlessly expurgated. Smithers' edition in 12 volumes (1894) restored most, but not all, of the omissions. Burton had considerable knowledge of the seamy side of eastern life, and his version is much sought after for its notes and commentary. The French translation of J. C. Mardrus, begun in 1899, is well known, but not highly esteemed among scholars. Not only is the text inaccurate, but it also includes stories which do not really belong to the *Nights*. Space does not permit the listing of the many translations into various European languages, but an outstanding example is the German translation of E. Littmann first published at Leipzig in six volumes (1921–28) with second and third editions in 1953 and 1954.

**Origins and Contents.**—European orientalists have been interested in the origins of the work from the beginning of the 19th century onward. Antoine Isaac Silvestre de Sacy (1758–1838; *q.v.*) realized that it could not be the work of a single writer; though Lane thought otherwise. There is now general recognition that it is a composite work which consists of popular stories, probably originally told orally: it has grown in the course of the centuries, material being added somewhat haphazardly in different periods and places. This is borne out by the style, which is largely unstudied and unaffected, with a number of colloquialisms, and even grammatical errors, such as no self-respecting Arabic author would have permitted himself. The varied character and wide geographical diversity of origin of the material also makes a single authorship unlikely. The component elements can be traced to India, Iran, Iraq, Egypt and Turkey, and Gustave von Grunebaum

in *Medieval Islam* (2nd ed., 1953) also postulated Greek elements. The general framework may be Indian, though the names of the chief protagonists are Iranian. There are Indian, Iranian, Turkish and even European proper names, but, as is only to be expected in an Islamic work, the majority of names are Arabic. The stories come under several categories. Some of them may be classed as fairy tales: *Aladdin and the Magic Lamp*, *Ali Baba and the Forty Thieves*, the *Merchant and the Djinni*, etc. There are also romances and love stories; adventure stories such as *Sindbad the Fisherman*; fables and parables; and a few Arab legends. But the Arab background portrayed is largely that of the Baghdad of Harun al-Rashid and the Cairo of the Fatimids and Mamelukes.

Nabia Abbott discovered the first known reference to the *Thousand and One Nights* (See “A Ninth-Century Fragment of the ‘Thousand Nights’,” in *Journal of Near Eastern Studies*, 1949). Next, the work is mentioned by al-Masudi (*q.v.*) in his *Muraj al-Dhahab* (947). In discussing legendary stories which have come from Iran, India and Greece, he instances “the book *Hazar Afsana*, which in Persian means ‘A Thousand Tales.’” “The people,” he says, “call this book ‘A Thousand Nights,’” and it is the story about the king, the vizier, the latter's daughter and her servant girl. These two are named Shirazad and Dinazad. The *Fihrist* (987) of Ibn al-Nadim mentions the *Hazar Afsana* and outlines the frame story. It then goes on to describe how a certain Abu Abdullah ibn ‘Abdus al-Jashyari (d. 942) began writing a collection of 1,000 stories of the Arabs, Iranians, Greeks and other peoples. At his death, he had only completed 480 of them. The existence of some form of the work in Fatimid Egypt is vouched for by al-Qurti, who wrote a history of Egypt under the last Fatimid ruler (1160–71).

August Müller, in 1887, distinguished several layers in the work, including one belonging to Baghdad, and another, much larger and later, written in Egypt. This idea was worked out in greater detail by T. Nöldeke, and especially by J. Oestrup in *Studier over 1001 Nat* (1891). The contents were also discussed by J. Horowitz in his article “Die Entstehung von Tausendundeine Nacht” in the *Review of Nations*, no. 4 (April 1927). Nabia Abbott suggests the following successive forms of the *Nights*: (1) An 8th-century Arabic translation of the *Hazar Afsana*, probably full and literal, and entitled *Alf Khwafa*. (2) An 8th-century Islamized version entitled *Alf Layla*. (3) A 9th-century version based on the above, and augmented by other current stories, such as those about Sindbad. (4) Ibn ‘Abdus’ work, mentioned above, possibly containing much material from 1, 2, and 3. (5) A 12th-century collection, including Egyptian stories. The title *Alf Layla wa Layla* may date from this period. (6) The final form of the work, extending into the 16th century. Additional material probably included stories of Islamic counter-crusades and far-eastern tales brought to the middle east by the Mongols.

The original title, *A Thousand Stories*, was not meant to be accurate, but merely to indicate a large number. Littmann suggests that the change to “1,001” came under Turkish influence, from the Turkish idiomatic expression *bin bir* (“1,001”) for a large number. Later, it was felt necessary to justify this title by adding stories, in order to complete the number.

Elisséeff, *Thèmes et motifs des mille et une nuits* (1949); and article by E. Littmann “Alf Layla wa-Layla” in *Encyclopaedia of Islam*, fasc. 6, vol. 1, 2nd ed. (1956). (J. A. Ho.)

**THRACE** (Greek ΘΡΑΚΙΑ, Latin THRACIA), an ancient and modern district whose boundaries have varied at different times. To the ancient Greeks Thrace was the eastern section of the Balkan peninsula between the Danube and the Aegean Sea, bounded on the east by the Euxine (Black) Sea and by the Straits, and on the west approximately by the mountains east of the Axios (Gr. Axios; Serb. Vardar) River. The land west of the Strymon (modern Gr. Strimon; Bulg. Struma) was incorporated into Macedonia soon after 480 B.C. and the remaining area is usually what is meant by Thrace in modern times; it corresponds to part of (sometimes all of) modern Bulgaria, together with the Greek province of Thrace and European Turkey.

Thrace is intersected by the Haemus (Balkan) Range (sometimes regarded as its northern boundary) and by the Rhodope chain which runs south and east from the Haemus toward the Aegean. Near the junction of Haemus and Rhodope, in the Rila Mountains south of Sofia, rises the Hebrus (Gr. Evros; Bulg. Maritsa), the largest Thracian river, which flows east to Edirne (Adrianople) and then turns south to the Aegean.

**Ancient Population.**—In ancient times most of Thrace was inhabited by various tribes of Thracians. North of the Haemus lived the Getae (*q.v.*). Farther south the leading tribes were the Odrysae with a capital near the later Philippopolis (Plovdiv), the Bessi probably on their southern boundaries, the Denteleetae on the upper Strymon, the Edones nearer the sea, the Sapaei on the lower Nestus, and the Dolonci in the Thracian Chersonese (Gallipoli [Turk. Gelibolu] Peninsula). Outside the Balkans the peoples of Bithynia and of Phrygia in Asia Minor were accounted of Thracian origin, as were the Dacians north of the Danube; and west to the Adriatic there had originally been Thracians, who were driven back by Illyrian invaders about 1300 B.C.

The Thracians spoke an Indo-European language and in early times had a fairly advanced culture, noted for its poetry and music. The Greek god Dionysus came from Thrace, where he had been a deity of vegetation; and the Greeks were impressed by the belief in immortality associated with the worship of the god Zalmoxis (*see GETAE*). But the Greeks of the 5th century and later regarded the Thracians as barbarians. Their methods of fighting were savage; the ecstatic rites of the god Sabazius were notoriously unrestrained; and Herodotus (*esp. iv, 93 ff. and v, 2 ff.*) notes the customs of tattooing and of allowing girls complete license until marriage. Thucydides, writing about 400 B.C. (*ii, 95 ff.*), has valuable information on the ethnography and political condition of the country in his day, and records that King Sitalces drew a revenue of 400 talents, a sum rather smaller than the contemporary tribute of the Athenian Empire. Throughout their history the Thracians were noted for lack of political cohesion, but they were valued as mercenaries, not least in Roman imperial times.

**Greeks and Macedonians.**—Many Greek cities were founded on the coasts of Thrace. The best-known were Byzantium and the other colonies on the Bosphorus, the Propontis (Sea of Marmara), and the Chersonese. On the Aegean were Abdera, near the Nestus mouth, and Aenus, near Alexandroupolis. Then there were the cities of the Chalcidic Peninsula, flanked on the east by the gold-bearing district of the Strymon valley, where after many unsuccessful attempts at Greek settlement the Athenians founded Amphipolis in 437 B.C. Farther north, in the Gulf of Burgas on the Black Sea, the Milesians founded Apollonia in the 7th century and the Chalcedonians Mesembria at the end of the 6th.

Most Thracians became subject to Persia c. 510 B.C., and some tribes joined the expedition of Xerxes against Greece in 480. But it was notoriously difficult to unite the country, although such a union was momentarily achieved later in the 5th century under King Teres of the Odrysae and his son Sitalces, the latter of whom invaded Macedonia with 150,000 men in 429. This expedition, however, collapsed under its own weight. In 360 the united kingdom split into three parts, and Philip II of Macedonia easily conquered the western region in 356 and in 342 made the remaining tribes tributary, as well as founding Philippopolis and other colonies. The Thracians provided Philip's son, Alexander the Great, with valuable light-armed troops, but Macedonian hold over the country was never secure. Lysimachus, one of Alexander's successors, founded Lysimachia in the Chersonese, and maintained his influence in all Thrace. But after his death (281) an invasion of Gauls dominated the interior, and it was with difficulty that the various Hellenistic kingdoms (including Egypt) controlled the Greek cities of the Aegean coast and the Straits. In 200 B.C. Philip V of Macedonia occupied all the cities up to the Hellespont and conquered certain tribes to the north. But after his defeat by the Romans in 197 the Roman Senate was favourable to other claimants, particularly the kingdom of Pergamum, until in 168 the Macedonian kingdom was destroyed.

**Roman Thrace.**—The coastal area west of the Hebrus was

annexed to the "First Republic of Macedonia" (and later to the Roman province of the same name), while Rome became increasingly involved in the affairs of the whole region. The Via Egnatia, a great military road, was built from Thessalonica (Salonika), and ultimately from Dyrrachium (Durrës), to the Hebrus, and many Roman governors of the late 2nd and early 1st centuries B.C. fought against Thracian tribes; as late as 13–11 B.C. the Bessi rose against Rome. Meanwhile, however, Cotys, king of the Sapaei, had succeeded in forming a widespread Thracian kingdom and was recognized as a Roman client king. At the beginning of the Christian era Cotys' son Rhoemetalcus ruled all Thrace south of the Haemus and east of the Roman province of Macedonia. On his death about A.D. 14 the kingdom was divided between his brother Rhascuporis and his son Cotys, but Rhascuporis murdered his nephew and Rome intervened with an army in 19. More sizable forces were required in 21 and 26 to deal with popular risings, the second caused by Roman recruitment of Thracian auxiliaries.

Finally the dynastic quarrels of the Sapaeian house led to annexation of the kingdom by the emperor Claudius in 46. A province was created under a Roman procurator, whose subordinates were native *strategi* (perhaps as many as 50), each controlling a small district. Several Greek cities, such as Abdera, remained "free," and Byzantium was put under the governor of Bithynia on the other side of the Bosphorus. About 114 Trajan replaced the procurator by a senatorial legate of praetorian rank, who controlled troops and had his headquarters at Perinthus (Eregli) on the Propontis. Both Trajan and his successor Hadrian founded numerous cities in Thrace, notably Serdica (Sofia) and Hadrianopolis (Adrianople). (G. E. F. C.)

South of the Danube, Moesia (*q.v.*) had been established as a separate province from A.D. 15. In the mid-3rd century Goths and other invaders ravaged much of Moesia and Thrace; Philippopolis was betrayed to them in 250–251, and many of its inhabitants were slaughtered. About 300 Diocletian reorganized the whole area between the lower Danube and the Aegean as the diocese of Thrace, divided into six provinces.

The foundation of Constantinople increased the importance and prosperity of Thrace, but in the late 4th century the barbarian raids resumed. In 378 the emperor Valens was defeated and killed near Adrianople (*see EDIRNE*) by the Visigoths, and in 443 and 447 Attila led the Huns on devastating raids far into Thrace. As early as the 1st century A.D. bodies of barbarians had been settled in the Danubian frontier provinces by the Romans, and this practice became more common in the 3rd and 4th centuries. In the late 6th and early 7th century the population of Thrace was drastically altered by massive Slav immigrations.

**Byzantines and Bulgarians.**—The Byzantines lost Thrace north of the Haemus when the Bulgarian state was founded in the late 7th century, and throughout the next three centuries there were both Bulgarian raids and actual Bulgarian conquests of much of the rest of Thrace. To organize the Byzantine defense, Nicephorus I created the theme (military district) of Thrace, but his defeat by Krum (811) led to more Bulgarian expansion. The Russian invasion of 969–971 gave John I an opportunity to recover much of Thrace, and the brief Bulgarian revival under Samuel was crushed by Basil II in 1014. But the Slav population was restive, and there were raids in the 11th and 12th centuries by tribes from beyond the Danube, especially the Turkic Patzinaks (Pechenegs).

After the fall of Constantinople to the Franks in 1204, southern Thrace passed to the Latin emperor Baldwin; the north was part of Bulgaria. Attacks by both Bulgarians and the Greek rulers of Epirus and of Nicaea soon diminished Latin territory, and in 1261 all Thrace was once more divided between the Bulgarian and Byzantine empires.

**Turks.**—Thrace suffered in the Byzantine civil wars of the early 14th century, and Turkish attacks on it began at this time. In 1354 the Ottoman Turks captured Gallipoli and used it as a base for the conquest of all Thrace; Adrianople was taken in 1362, Philippopolis probably the following year. Bulgaria soon submitted, and apart from Constantinople and nearby areas (until

1453) all Thrace became Turkish. The *eyalet* of Rumeli (Rumelia), with its capital first at Filibe (Plovdiv), then at Sofia, embraced Thrace and neighbouring Ottoman conquests in the Balkans.

**19th and 20th Centuries.**—Turkish domination in the Balkans was undisputed for about four centuries, but the establishment of Russia on the Black Sea, and especially the Treaty of Kuchuk Kainardji (1774), giving Russia the right to protect the Christian populations of the Ottoman Empire, started a chain reaction which resulted in the almost total loss of Turkish possessions in Europe. (See EASTERN QUESTION.)

Thrace became for the first time a theatre of a Russo-Turkish war in 1828–29 and for the second time in 1877–78. Russia failed, however, in creating a "Big Bulgaria" because in 1878 the European powers decided (see BERLIN, CONGRESS OF) that the Balkan range would be the southern frontier of the newly created Bulgaria. The whole of Thrace remained under Turkish domination, but its northern fringe, with a Bulgarian population, became an autonomous province named Eastern Rumelia. This situation ended in 1885 when Eastern Rumelia was united with Bulgaria.

During the first Balkan War of 1912–13 (see BALKAN WARS) Thrace once more became a battlefield, this time between Bulgars and Turks. The Bulgars took Edirne (March 26, 1913) and thus were masters of nearly all Thrace. But Ferdinand, king of Bulgaria, remembering that Russia included Macedonia in its plan for "Big Bulgaria," ordered on June 28 an attack upon the Serbs and the Greeks. Thus started the second Balkan War, which ended badly for Bulgaria. Under the Treaty of Bucharest (Aug. 10, 1913), Turkey recovered all Eastern Thrace with Edirne, but Bulgaria obtained Western Thrace with a coastline of about 125 mi. on the Aegean and with a small port at Dedeagach (Alexandroupolis).

That settlement did not survive World War I, in which Bulgaria sided with Germany, Austria-Hungary, and Turkey. After the defeat of the Central Powers, the frontiers across Thrace were revised in favour of Greece, which by the Treaty of Neuilly (1919) obtained the southern part of Eastern Thrace and by the Treaty of Sévres (1920) almost all of Western Thrace. Greek tenure of Eastern Thrace was brief: after the disastrous end of the Greek invasion of Anatolia, the Treaty of Lausanne (1923) restored Eastern Thrace up to the Maritsa to Turkey, leaving Western Thrace to Greece. At that time Eastern Thrace had a total population of about 805,000, including 395,500 Greeks, 344,000 Turks, and 67,800 Bulgars. That part of Western Thrace which was attributed to Greece had a total population of about 200,000, including 124,000 Turks, 44,000 Greeks, and 29,500 Bulgars.

The frontiers between Bulgaria, Turkey, and Greece remained unchanged after World War II. The historic Thrace remained divided between those three states: about 7,350 sq.mi. was in Turkey, 3,295 sq.mi. in Greece, and 2,920 sq.mi. (respectively 19,000, 8,500, and 7,500 sq.km.) in Bulgaria. But between the two world wars the ethnic composition of the population changed greatly in all three parts of Thrace. In the 1920s Greeks were repatriated to Greece and Bulgars to Bulgaria. In the 1960s the total populations in the three parts of Thrace were 792,000 in Turkey, 357,000 in Greece, and 372,000 in Bulgaria. The only national minority of some importance was the Turkish one in Greek Thrace, numbering about 92,000.

**THRASEA PAETUS, PUBLIUS CLODIUS** (d. A.D. 66), Roman senator famous for his opposition to the emperor Nero. He came from the north Italian middle class. He was consul in 56 and took an independent line on various occasions in Nero's reign; he walked out when the Senate congratulated Nero on his mother's death (59), and out of disgust with Nero's immoralities retired altogether from public life from 63 to 66. This protest

was all the more striking because in earlier years he had been notably active; as late as 62 he initiated an important measure to prevent provincial governors from becoming dependent on the favour of unscrupulous local magnates. In 66 his enemies persuaded Nero to order his death on the ground that he had become almost the head of a rival party in the state; in fact there is no evidence that Thrasea would ever have carried opposition to the point of conspiracy. He spent his last hours in a discussion of the immortality of the soul. Helvidius Priscus (q.v.) was his son-in-law, and the poet Persius (q.v.) was his friend.

See E. Groag and A. Stein, *Prosopographia Imperii Romani*, 2nd ed., vol. ii, C 1187 (1936); C. Wirszubski, *Libertas as a Political Idea at Rome*, pp. 138 ff. (1950). (P. A. Br.)

**THRASHER**, a group of birds belonging to the same American family, Mimidae, as the mockingbird (q.v.). Perhaps the best of these accomplished songsters is Sennett's thrasher (*Toxostoma longirostre*) of southeast Texas and northeast Mexico, but the

ALLAN D. CRUICKSHANK FROM THE NATIONAL AUDUBON SOCIETY  
BROWN THRASHER (*TOXOSTOMA RUFUM*) OF EASTERN NORTH AMERICA

brown thrasher (*T. rufum*) of eastern North America also has a fine song. A third species is the sage thrasher (*Oreoscoptes montanus*) of the southwestern United States. All thrashers are birds of bushy thickets, where they build fairly bulky cup-shaped nests of twigs, in which they lay three to six whitish or pale greenish eggs, heavily speckled with brown. In spite of their arboreal nature, thrashers to a large extent feed on the ground.

The catbird (*Dumetella carolinensis*), a North American thrasher about nine inches long, breeds from Nova Scotia to southeastern Texas. Its plumage is slate gray, with a black cap and tail and chestnut under tail coverts. It is noted for its distinctive song, which, although having much of the charm of its close relative the mockingbird, is interspersed with petulant mewing protests, hence its common name. The catbird winters in the southern states, in Cuba and from Mexico to Panama. It is resident in Bermuda. Unlike most of its relatives, it lays deep glossy blue-green eggs.

Thrashers are beneficial in view of their insect-eating habits.

**THRASYBULUS** (d. 389 or 388 B.C.), Athenian general and democratic leader. His public career began in 411 B.C., when he frustrated the oligarchic rising in Samos (see PELOPONNESIAN WAR). Elected general by the troops, he effected the recall of Alcibiades (q.v.) and assisted him in the ensuing naval campaigns, contributing to the victories of Cynossema (411) and Cyzicus (410), after which he remained in the Hellespont area and recovered Thasos (407) and Abdera for Athens. He commanded a ship at Arginusae and was commissioned with Theramenes (q.v.) to rescue the men on the wrecks. In 404, when exiled by the Thirty (the oligarchy at Athens), he retired to Thebes. In the following winter, with 70 men, he seized Phyle, a hill fort on Mt. Parnes. His supporters soon increased, and with 1,000 men he gained the Piraeus and held Munychia against an attack by the oligarchs. Eventually a Spartan expedition under king Pausanias arrived and the democracy was restored (autumn 403). Thrasybulus was now the hero of the people; but a decree by which he secured the franchise for all his non-citizen followers was rescinded as illegal (some of these were in fact enfranchised in 401/400).

In 395 Thrasybulus induced Athens to join the Theban League against Sparta; next year he took part in the Battle of Nemea. In 389 he led a new fleet of 40 ships against the Spartans at Rhodes. He effected a democratic revolution at Byzantium and renewed the toll on the Bosphorus trade. After a successful attack on Lesbos and the reimposition of the 5% import tax on the Athenian allies, he sailed south and was killed at Aspendus, where his financial exactions had made him unpopular.

**THREE BODIES, PROBLEM OF**, the problem of determining the motion of three heavenly bodies moving under no influence but that of their mutual gravitation. No general solution

of this problem is possible. As practically attacked it consists of the problem of determining the perturbations or disturbances in the motion of one of the bodies around the principal or central body that are produced by the attraction of the third. Examples are the motion of the moon around the earth as disturbed by the action of the sun, and of one planet around the sun as disturbed by the action of another planet. For application of the problem to asteroids, see TROJAN PLANETS.

**THREE RIVERS:** see TROIS-RIVIÈRES.

**THRESHING:** see FARM MACHINERY; CROP-PROCESSING MACHINERY.

**THRING, EDWARD** (1821–1887) ranks with Thomas Arnold as one of the outstanding English schoolmasters of the 19th century. Born at Alford, Somerset, on Nov. 29, 1821, he was educated at Eton and King's College, Cambridge. Ordained in 1846, seven years later he was appointed headmaster of Uppingham School (founded 1584), which he transformed from a small country grammar school into a large public school, in spite of opposition from his governors. Fearing that the independence of the school was threatened by the Endowed Schools Commissioners, he formed in 1868 the Headmasters' Conference, which thereafter had a great influence in English public school education. Thring remained as headmaster until his death on Oct. 22, 1887. He believed that every boy could do something well and that the business of the master was to discover what this was.

He built the school chapel, opened in 1859 the first school gymnasium in England, started wood and metal workshops, and provided a swimming pool and opportunities for school gardening. At the same time he stressed a sound training in classics, mathematics, and English. Thring realized the refining and stimulating power of music in education and built up a strong musical tradition at Uppingham.

To help young teachers, he wrote *Theory and Practice of Teaching* (1883).

**THRIPS**, any of the small insects comprising the order Thysanoptera, which include such plant pests as the onion thrips, gladiolus thrips, wheat thrips and greenhouse thrips. In addition to inflicting injury some thrips transmit virus diseases of plants. Most thrips are less than one-tenth inch long; even giants of the order, found in the tropics and Australia, are scarcely one-half inch long. Because of their small size and their habit of hiding in close places thrips are commonly overlooked, even by entomologists, and not more than 5,000 species have been described. Thrips occur in every part of the world where plants grow. They feed on green plants, decaying plant remains, fungi or small insects and mites. Most of them extract sap or juice, but one group of species ingests the spores of fungi instead of juice. Although they are of no importance to human health, thrips, when numerous, may annoy persons by pricking thin skin in search of water; one of the plant feeders has been reported to ingest human blood occasionally. Some species are restricted to a single kind of food plant, whereas others may prefer certain plants or feed on many different plants. Thrips may curl leaves

or fold them along the mid-vein to create a shelter, and at least one species induces hornlike galls.

Thrips are elongate, slender-bodied insects, with antennae consisting of four to nine true joints, and with asymmetrical piercing mouthparts. The wings have reduced venation and are usually long and narrow, with marginal fringes of long hairs; but some species or individuals have no wings or only short, nonfunctional ones. Each of the one- or two-jointed tarsi bears at the apex a minute protrusible bladder, which is an aid to a thrips in climbing even the smoothest surface. The young resemble the adults in form but are paler and more brilliantly coloured. Before becoming adult, they pass through a prepupal and one or more pupal stages. Males are generally scarcer than females and in some species are rare or unknown. Even in species where males are common, reproduction is often effected without them, through parthenogenesis (*q.v.*).

Thysanoptera are divided into two suborders: (1) Terebrantia (female with sawlike ovipositor and usually a conically pointed abdomen; male with abdomen bluntly rounded); and (2) Tubulifera (female without ovipositor; both sexes in most species with the last segment of the abdomen tubular in form). The Terebrantia are the more primitive group, with more veins in the wings and often with the wings relatively broad. Most species of this group feed on living plants; some are predatory. The female usually inserts the eggs under the epidermis of the plant by means of her ovipositor. The Tubulifera are more specialized: the ovipositor has been lost, the antennae have usually fewer segments, the wings are narrow and the veins have been reduced to a single median vestige. Most species of this group feed on plant debris and fungi or fungus spores, although a few are plant feeders or predators. Lacking an ovipositor, the female usually hides the eggs in protected places. The young are born alive in some species. Fossils of both suborders, especially of Terebrantia, are known. See also INSECT.

**BIBLIOGRAPHY.**—H. Priesner, *Die Thysanopteren Europas* (1926–28), contains a good bibliography of earlier works; S. F. Bailey has published bibliographies of North American authors in the *Florida Entomologist*, 30:17–24 (1947), 31:35–49 (1948), 32:11–36 and 32:114–131 (1949); L. J. Stannard, *Illinois Biol. **THROAT (PHARYNX)**, in human anatomy, a passageway leading from the oral and nasal cavities to the esophagus (gullet) and larynx (voice box). Strictly speaking, pharynx is a broader term than throat, the latter being restricted to only part of the pharynx. In medical practice, however, the two terms ordinarily are used interchangeably, and they are so used in this article.

The throat passes the intake of solids and liquids to the esophagus in eating or drinking and conducts air to and from the larynx in breathing. The throat also communicates on either side with the cavity of the middle ear by way of the auditory (Eustachian) tube; this provides for equalization of air pressure on the eardrum membrane, which separates the cavity of the middle ear from the external ear canal (see EAR, ANATOMY OF).

**Anatomy.**—The throat has roughly the form of a funnel flattened from front to back, about 12 cm. (5 in.) long and narrowing from a width of about 5 cm. (2 in.) at the base of the skull to 2.5 cm. at its junction with the esophagus. The wall of the pharynx is attached by its connective tissue and muscles to surrounding structures. The firmest attachments (in addition to continuities with the walls of the oral cavity, Eustachian tubes, esophagus and larynx) are with basal parts of the skull, mandible, tongue, hyoid bone and the thyroid and cricoid cartilages of the larynx. The outermost connective tissue is in

GROWTH STAGES OF PEAR THRIPS (TAENIOTHRIPS INCONSEQUENS)

most areas loose enough in organization to admit gliding of the pharyngeal wall, in the movements of swallowing, against the surrounding structures.

Three main divisions of the throat are distinguished: oral pharynx, nasal pharynx and laryngeal pharynx (*see figure*). The latter two are airways, whereas the oral pharynx is shared by the respiratory and gastrointestinal tracts. Some of the boundaries of these divisions may be observed in a person whose mouth is held wide open. Note first the palatine tonsil, enfolded between two vertical folds of mucous membrane (in front, the glossopalatine arch; behind, the pharyngopalatine arch). A plane coinciding with the glossopalatine arches on the sides of the throat, and with the junction of the front two-thirds and back one-third of the tongue on its floor, represents the approximate boundary between mouth cavity and oral pharynx. Above, the hard palate separates the oral cavity from the nasal cavities; the soft palate partitions the oral pharynx from the nasal pharynx. The free edge of the soft palate is prolonged in the midline as the teatlike uvula. The laryngeal pharynx and the lower part of the oral pharynx are hidden by the bulging of the root of the tongue. An important feature of this obscured region is the epiglottis, a laryngeal flap that guards the glottis as a deflector between the laryngeal pharynx and the lowermost oral pharynx.

The wall of the throat is divisible into principal layers, from within outward: (1) mucous membrane, consisting of epithelium and fibrous connective tissue, of which the outermost part, a tough membrane called the pharyngeal aponeurosis, is especially concerned with the upper and lower attachments of the throat; (2) muscle; (3) connective tissue. The muscle is subject to voluntary control and is concerned in the mechanics of swallowing (*see DIGESTION: Swallowing*). The mucous membrane contains numerous minute salivary glands (*q.v.*).

The throat is the seat of the tonsils. The term tonsil may suggest only the palatine tonsils, whose position is described above,

FROM A. BIRMINGHAM, "CUNNINGHAM'S TEXT BOOK OF ANATOMY"; OXFORD MEDICAL PUBLICATIONS  
SECTION THROUGH HEAD SHOWING PHARYNGEAL PASSAGeways

but these are only components of a series of tonsils encircling the wall of the pharynx. On either side, in addition to the palatine tonsil, is the tubal tonsil, near the orifice of the Eustachian tube. On the roof of the nasopharynx is the pharyngeal tonsil, which is frequently so enlarged in children as to obstruct the airway (*see ADENOIDs*). On the floor of the oral pharynx, in the back one-third of the tongue, is the lingual tonsil. All these tonsils are masses of lymphoid tissue imbedded in the mucous membrane; this tissue is composed principally of lymphocytes, a variety of white blood cell. Normally, the tonsils become smaller in adulthood.

**Comparative Anatomy.**—Broadly defined, the pharynx is the segment of the alimentary tract in direct continuity with the mouth cavity. In the simpler invertebrates the pharynx does not exist

because at this level of structural organization there is no alimentary tract equivalent to that of higher forms. Even in some invertebrates that possess an alimentary tract the pharynx as such is absent, the passage leading from the mouth being termed esophagus or stomach. The invertebrates that have a pharynx exhibit variations of its construction and functions. In leeches, for example, the pharynx has a robust musculature and serves as a suction pump to extract blood from the prey whose skin has been pierced by the teeth of the leech. In certain marine worms the wall of the mouth cavity and pharynx may be turned out and protruded for the ingestion of food; the interior of the pharynx may bear papillae or even horny teeth that aid in the process of ingestion.

The pharynx in invertebrates as a whole is not the strict homologue of the pharynx in vertebrates; the likeness between them is only the analogy of their sequential relations in the alimentary tract. In chordate animals (*i.e.*, vertebrates and their immediate kin) the pharynx is consistent not only in the fundamentals of structural relationship but also in embryologic derivation, and hence is homologous throughout.

The classes of vertebrates present wide variation in the character of the pharynx. In all lung-breathing forms (mammals, birds, reptiles, and most amphibians in their postlarval stages) the pharynx is constructed in principle like that of man, though varying in anatomical details. The possession of gills (*q.v.*) in relation to the pharynx is a primitive feature, and gill-breathing vertebrates reflect the basic pharyngeal pattern that characterizes the chordates as a group. Gills are retained throughout life in fishes and in some tailed amphibians (*e.g.*, *Necturus*, the mud puppy). Gills in some animals (*e.g.*, larval amphibians and the adult *Necturus*) are tufted external appendages. Typically in fishes, however, the gills are internal and in more direct relation with the pharynx. A shark, for example, presents on each side of the "neck" a series of gill slits, usually five in number, exclusive of the front opening known as the spiracle. These slits are communications between the pharynx and the outside, the gills being anchored within the slits where they are bathed with water issuing from the pharynx. A characteristic of bony fishes is the operculum, a protective flap overlying the gills and bordering the single gill opening.

In the embryonic history of lung-breathing vertebrates the pharynx is first modeled in the primitive pattern—as if gills were to develop, which they actually do in abortive and transitory fashion in the embryos of some of these animals. As an occasional anomaly in human development, one or more "gill slits" may persist, with or without opening into the pharynx.

**THROAT, DISEASES OF.** The throat is subject to diseases that affect its muscular wall, as in paralysis, or its lining, as in infection by bacteria, viruses, or fungi. Infection by streptococci usually produces acute tonsillitis (*q.v.*) with swelling, pain, and fever. If the infection reaches the space behind the tonsil, an abscess may form and produce quinsy, with extreme pain, difficulty in swallowing and inability to open the mouth. Scarlet fever (*q.v.*) is a streptococcal throat infection accompanied by a skin rash. Streptococcal infections of the throat are effectively treated with sulfonamide drugs and penicillin.

Repeated infections usually result in enlarged tonsils and adenoids (*q.v.*), with obstruction to breathing and swallowing. Enlarged adenoids are the commonest cause of deafness in children. Adenoidectomy, usually done with tonsillectomy, restores normal hearing in such cases. These structures, which normally serve a useful purpose, should not be removed unless they are the site of repeated or intractable infection.

Diphtheria (*q.v.*), an acute specific bacterial infection of the throat, is rare where routine immunization is carried out in childhood. It can be cured by antitoxin if recognized early, but untreated it is often fatal. Other throat infections may be caused by viruses (mononucleosis [*see* INFECTIOUS MONONUCLEOSIS], herpangina) or may occur when the body's resistance is weakened

by a scarcity of white blood cells, a condition often due to drug sensitivity and occasionally to prolonged X-ray exposure.

The muscular wall of the throat may be weakened or paralyzed by virus infections of the supplying nerves (poliomyelitis, rabies, etc.), by toxins from diphtheria or infected food, by chemical agents (e.g., lead, methyl alcohol), or by circulatory disturbances of the brain, especially in the aged. Spasm of the lowermost constrictor muscle may result from emotional tension, producing the sensation of "lump in the throat."

Cancer of the throat is not common. It may begin as a painless swelling in the region of the tonsil, diagnosable by biopsy. X-ray treatment is often effective in controlling it.

Infections of the larynx or voice box (laryngitis; *q.v.*) may produce hoarseness, and in young children, a difficulty in breathing, known as croup (*q.v.*), which is treated by steam inhalation and antibiotics. A rare form of croup, due to diphtheria, may require surgical opening of the windpipe to provide an airway. Tuberculous laryngitis is effectively controlled by streptomycin.

Hoarseness may be due to "singers' node" of the vocal cord, usually associated with overuse of the voice, or to vocal polyp, often found in excessive smokers. Since hoarseness is also an early symptom of cancer involving the larynx, it should be investigated by a physician if it lasts more than two weeks. Laryngeal cancer can be cured in most cases if discovered early. X-ray therapy can cure most small cancers of the vocal cord, whereas surgical removal of the larynx is required for extensive growths.

See A. R. Hollender (ed.), *The Pharynx* (1953). (J. A. Kl.)

**THROCKMORTON (THROGMORTON), FRANCIS** (1554–1584), English conspirator in a plot to overthrow Elizabeth I, was the son of Sir John Throckmorton of Feckenham, Worcestershire, and the nephew of Sir Nicholas Throckmorton (*q.v.*). Sir John had been concerned in the rebellion (1554) of Sir Thomas Wyatt against Mary I, but he later regained her favour and became chief justice of Chester.

Francis entered Hart Hall (afterward Hertford College), Oxford, in 1572, and in 1576 he was enrolled in the Inner Temple. At Oxford he came under Roman Catholic influence, and when Edmund Campion and Robert Parsons came to England in 1580, as the first of the Jesuit missionaries, he was one of a society of members of the Inner Temple who hid them and gave them help. In that year he went abroad. He returned to London in 1583 to act as the confidential agent of a conspiracy, involving France and Spain, which had for its object the invasion of England by a French force under Henry, duc de Guise, for the purpose of freeing Mary Stuart, queen of Scots, and restoring papal authority.

Throckmorton occupied a house on Paul's Wharf, London, which served as a centre of communication for the conspirators. The suspicions of the government being aroused, he was arrested in November 1583. Before being taken to the Tower of London he was able to send a casket of compromising letters to Mendoza, the Spanish ambassador, and later a card in cipher in which he promised to reveal nothing. He was tortured on the rack at the Tower and after being threatened with further racking he made a full confession. He was tried on May 21 and executed at Tyburn on July 10, 1584. His arrest and confession led to the expulsion of the Spanish ambassador.

**THROCKMORTON (THROGMORTON), SIR NICHOLAS** (1515–1571), English diplomat in the reign of Elizabeth I, was a son of Sir George Throckmorton of Coughton, Warwickshire, and the uncle of Francis Throckmorton (*q.v.*). A member of the household of Catherine Parr, the last wife of Henry VIII, he was favourable to the reformers in religion. He was a member of Parliament from 1545 to 1567. During the reign of Edward VI, in which he was knighted (1547), he at first supported Protector Somerset but later went over to the party of the earl of Warwick (afterward duke of Northumberland). When, on the death of Edward (1553), an attempt was made to place Lady Jane Grey on the throne instead of Mary Tudor, Throckmorton contrived to appear the friend of both parties; but on Mary's accession he was able to secure her favour. He was, however, suspected of complicity in the rebellion of Sir Thomas Wyatt (January–February 1554). Acquitted at his trial in April, he was detained in the Tower of

London until January 1555. He went abroad in 1556 but made his peace with Queen Mary in 1557.

Under Elizabeth I he became chamberlain of the exchequer and from May 1559 to April 1564 he was ambassador in France. During his embassy he was engaged in discussions about the return of Mary Stuart, queen of Scots, to Scotland (1561), and as a strong supporter of the Huguenots he was at the Battle of Dreux (December 1562) and was a prisoner for a short time. After the signing of the Treaty of Troyes (April 1564), between England and France, Throckmorton returned to England.

In May 1565 he was sent as ambassador to Scotland, but failed to prevent Mary's marriage with Henry, Lord Darnley. After Darnley's murder (February 1567) and the imprisonment of Mary by the Scottish Protestant lords (June) he was again sent to Scotland in July 1567 with the still more hopeless task of persuading the lords to restore Mary to the throne. He could effect little, but exerted himself to secure the personal safety of the queen. He offended Elizabeth by showing his instructions to the lords and returned to England in August. Throckmorton fell under suspicion in 1569 during the intrigue to marry the duke of Norfolk to Mary and was imprisoned for a time at Windsor Castle, but was not further proceeded against. He died in London on Feb. 12, 1571. Throckmorton married Anne Carew, and his daughter Elizabeth became the wife of Sir Walter Raleigh.

See A. L. Rowse, *Raleigh and the Throckmortons* (1962).

**THROMBOSIS AND EMBOLISM.** In certain disease states the process of coagulation (clot formation), initiated in a blood vessel, may proceed to the formation of a thrombus, a type of clot. Thrombosis (the formation of a thrombus) may produce symptoms by obstructing blood flow either at its site of formation or at some distant point in the vascular system; in the second situation, blood flow is blocked by an embolus, a fragment dislodged from the thrombus. (The blocking caused by an embolus is known as an embolism, or thromboembolism.) Thrombosis has much in common with clot formation and, while it may result from other indirect causes, is thought to be frequently related to an increased coagulability of the blood.

**Blood Coagulation.**—Knowledge of blood clotting is derived largely from studies on blood and blood fractions in the test tube. While there is much conflicting evidence regarding the sequence of activation and the relative importance of some of the newer clotting factors, blood coagulation is considered to occur in three successive stages, as follows:

- (1) platelets  $\xrightarrow[\text{VIII-XII}]{\text{IV, V}}$  thromboplastin (III)  $\xleftarrow{\text{III, IV}}$  tissues
- (2)  $\xrightarrow[\text{V, VII}]{\text{thrombin}}$  prothrombin (II)
- (3) fibrinogen (I)  $\xrightarrow[\text{IV}]{\text{thrombin}}$  fibrin (clot)

The stages are: (1) the activation of thromboplastin, an ill-defined product, released from the platelets or from injured tissue, that includes phosphorus-containing fatty proteins (phospholipoproteins); (2) the conversion of prothrombin to thrombin by thromboplastin; and (3) the splitting of fibrinogen to fibrin by the proteolytic action of thrombin. The fibrin, which is initially soluble, finally polymerizes into microscopic fibrils to form a gel, the fibrin clot. The various formed elements of the blood (red cells, white cells and platelets) become enmeshed at random in this interlacing network of tiny fibres.

The platelets have a special importance in initiating the processes of hemorrhage control (hemostasis), coagulation in the test tube and thrombosis. The first microscopic clue that a clot is going to develop *in vivo* is the gathering together of several of these small round bodies to form a conglomerate mass capable of plugging small leaks in the vessel wall and even occluding the lumen of small vessels. The initiation of this conglutination depends to some degree upon an increase in the adhesive quality of the platelets. This then somehow leads to the release of several active agents: thromboplastin, clotting factors serving to accelerate the second and third stages of coagulation, an antifibrinolytic, a vasoconstrictor (serotonin) and a hypotensive histamine sub-

stance. (Electron microscopy has shown that platelets rather quickly serve as a focus for fibrin formation.)

The fibrin clot will form only when all of the first four factors (I through IV) are present and will form but slowly when one or more of the other coagulants is absent. This suggests that the actions of the latter are of a catalytic nature. In patients deficient in any of these clotting factors bleeding may occur in varying degrees after minor trauma, and only rarely spontaneously. The best-known example is the patient with hemophilia A or B who suffers from a congenital lack of factor VIII or IX (*see HEMOPHILIA*).

Conversely, a shortened clotting time has been observed in men who have eaten a fatty meal; an increase in blood fat is known to occur at such a time. Whether the decrease amounts to a truly hypercoagulable state is not known. Thrombosis is common in the disease polycythemia vera and in other conditions characterized by an excess of or unusual stickiness of platelets. It has been further postulated that an excess of one or another clotting factor may also enhance the likelihood of intravascular thrombosis.

The time required for blood to clot in the test tube is approximately five minutes. Most of this is taken up by the first stage of coagulation, which, for optimum speed, requires the complex interaction of many factors: *i.e.*, calcium ions, accelerator globulin, antihemophilic globulin, Christmas factor, Stuart-Prower and Hageman factors, and plasma thromboplastin antecedent (*see table*); the second and third phases of coagulation are completed

Clotting Factors\*

Factor	Name (synonym)	Chemical nature
I . .	fibrinogen	glycoglobulin glycoglobulin phosphoprotein inorganic ion euglobulin
II . .	prothrombin	
III . .	thromboplastin	
IV . .	calcium	
V . .	accelerator globulin (Ac-globulin, proaccelerin, labile factor)	
VII†	proconvertin (serum prothrombin conversion accelerator, SPCA, stable factor)	beta and gamma globulins
VIII .	antihemophilic factor (antihemophilic globulin A, AHG, thromboplastinogen)	
IX . .	plasma thromboplastin component (PTC, Christmas factor, antihemophilic globulin B)	
X . .	Stuart-Prower factor	
XI . .	plasma thromboplastin antecedent (PTA)	
XII .	Hageman factor	

\*Nomenclature recommended in 1961 by the International Committee for the Nomenclature of Blood Clotting Factors.

(†) Factor VI is no longer listed in the nomenclature since, subsequent to the discovery of later factors, it was found that VI cannot be identified as an independent entity.

in perhaps 15 seconds, after active thromboplastin becomes available. In case of tissue injury and particularly of vascular injury, however, an active tissue thromboplastin becomes immediately available to initiate the second phase of coagulation; the slow process of thromboplastin generation from platelets thus is bypassed. Because of the presence of tissue thromboplastin in abundant amounts, lowered blood concentrations of the factors required exclusively in thromboplastin generation (VIII to XII) do not necessarily lead to prolonged bleeding after injury.

With the passage of a few hours, the clot shrinks in size in proportion to the number of incorporated platelets. The fibrin may dissolve under the influence of plasmin, a proteolytic enzyme (*i.e.*, a fibrinolysin) present in the blood. Plasmin is derived from the activation of a precursor, plasminogen. Agents such as streptokinase and urokinase have been used clinically as plasmin activators. It has been postulated that this thrombolytic activity must be one factor limiting the extent of clot formation, so that the clot does not grow to fill the entire vascular system. Less well defined are antithrombin and the inhibitors of other coagulants that act on thromboplastin activation; their function, when determined, may help explain why the blood, which clots so readily when removed from the body, remains liquid in the blood vessels.

**Pathology.**—Thrombosis may occur at any site in the cardiovascular system: artery, capillary, vein or chamber of the heart. A thrombus differs from a blood clot outside the body in that it is

organized into a less homogeneous structure; a basic grayish layer of agglutinated platelets of varying thickness is covered by a dense layer of fibrin that merges into a looser red fibrin layer, and it is the red fibrin layer that includes the white and particularly the red blood cells. A laminated thrombus is formed when several layerings are deposited one upon another. There are many variations in the proportions of white and red thrombotic material, depending partly upon the location of the thrombus.

Characteristically the arterial thrombus is richer in platelets packed together (white, or conglutination, thrombus). The venous thrombus most commonly has a "white head" at its attachment to the vessel wall and a long "red tail" streaming away from it toward the heart. This red, or coagulation, thrombus will, if the circulation is slow enough, quite closely resemble the *in vitro* blood clot. A fragment of this tail may break loose to form an embolus.

Reduction in the velocity of blood flow, roughening of the artery wall by disease or injury, certain toxic chemicals (*e.g.*, snake venom) and enhanced coagulability of the blood have all been considered important causative factors in thrombus formation. Thus, injury, surgery, general or local infection, arterial disease, heart failure, pregnancy, occasional malignancies and certain disorders of the blood all predispose to this complication. It is thus not surprising that thrombosis is found either incidentally or as the cause of death in the majority of all fatalities due to cardiovascular disease and that its frequency increases with advancing age.

Once thrombosis is contained, regardless of whether embolism has or has not occurred, the thrombus undergoes gradual changes: dissolution, then contraction, and finally organization. By these means a new channel for the flow of blood may ultimately be reestablished. Some pathologists feel that the organized residue of old arterial thrombi become incorporated into the arterial wall as arteriosclerotic plaques and thus contribute to the progression, and perhaps even the initiation, of hardening of the arteries.

Thrombosis occurs most often in the large veins of the pelvis and legs, the small arteries of the heart and the brain, and in the chambers of the left side of the heart, but, under appropriate circumstances, thrombosis may occur anywhere in the circulatory system. If the thrombosis occurs in a vein, the process is called phlebothrombosis and it may produce no symptoms unless it causes an embolism. Frequently, inflammation may cause local pain and swelling in the region drained by the affected vein, in which case the condition is designated thrombophlebitis.

While venous thrombosis may sometimes lead to a fatal embolism, it is not so great a threat to life as is arterial thrombosis. The coronary and cerebral arteries (*i.e.*, of the heart and brain) are often the site of arteriosclerosis, a thickening and irregularity of the vessel lining that may predispose to thrombus formation. Should thrombosis occur, the mass of heart muscle or brain ordinarily supplied by the obstructed vessel dies; if the victim survives the initial insult, healing follows with scar formation. Recovery will depend upon the extent of tissue involvement and the presence or absence of additional thromboses either attached to the lining of the injured heart wall or arising in the veins of the leg; those in the legs may give rise to fatal pulmonary emboli.

Emboli are usually composed of coagulated blood but in rare cases they may consist of tumour cells, air, fat particles or bacterial clumps (septic emboli). These traveling aggregates can lodge in distant parts of the vascular system and there obstruct the flow of blood. Emboli are a common cause of sudden death but they are by no means always fatal. An embolus that arises in the venous system or in the right side of the heart ordinarily will lodge in the ramifications of the pulmonary artery. If the embolus is large, one of the main pulmonary arteries will be obstructed and death occurs. If the embolus is small, the segment of lung nourished by the obstructed artery dies. (*See LUNG, DISEASES OF: Pulmonary Embolism.*)

In certain types of heart disease an embolus may originate from one of the chambers of the left side of the heart, or from the mitral or aortic valve therein, in which case the bloodstream will carry it to one of the branches of the peripheral arterial tree. Should

such an embolus lodge in certain internal organs, pain might be the only consequence; but occlusion of even a small artery in the heart, eye, brain, intestine or one of the extremities will lead also to the death of enough tissue to cause severe disruption, if not cessation, of function of the part. However, tissue death does not occur in all arterial obstructions, for in certain locations (e.g., liver and lungs) neighbouring (collateral) arteries can carry enough blood into the affected area to furnish adequate circulation.

**Anticoagulant Therapy.**—Although a hypercoagulable state of the blood has not been established as the primary cause for the most common types of thrombosis and embolism, it has been well established that reducing the normal tendency for the blood to clot may help to prevent recurrences of thromboembolism. Heparin, which occurs naturally in the lungs, liver and other tissues, is derived from meat animals slaughtered for human food; it is given by injection and may function in fat metabolism as well as in the control of coagulation. Bishydroxycoumarin (Dicumarol), a chemical originally derived from spoiled sweet clover but now synthesized, has a great advantage in that it may be taken orally. Both heparin and Dicumarol have been used widely since 1940 for their broad anticoagulant properties. Heparin is a complex polysaccharide combined with sulfuric acid that inhibits each of the three stages of clot formation. Dicumarol and the other related derivatives of coumarin (*q.v.*) were originally thought to depress the synthesis of prothrombin (factor II) by the liver; the dosage to be administered is determined by measuring the prothrombin activity of the blood. It was later reported that Dicumarol also suppresses the blood levels of factors VII, IX and X. Both heparin and Dicumarol are thought to decrease platelet stickiness, though dosage considerations suggest that this may not be regularly accomplished by the usual therapy.

There is little doubt that the appropriate use of anticoagulant drugs similar to heparin and the coumarins, as well as certain derivatives of indandione, has reduced the incidence of thrombosis and embolism in patients prone to these events. Particular benefit is seen in patients with thrombophlebitis and with peripheral arterial emboli from intracardiac thrombi. There is general if not universal agreement that the thrombotic and embolic complications of an acute coronary thrombosis are minimized and that the incidence of the coronary artery thromboses that sometimes follow may be reduced by continuous anticoagulant therapy. Although these drugs are helpful in controlling certain attacks of impaired blood flow to the brain, their use in apoplexy, or stroke (*q.v.*), remains controversial since the danger of causing cerebral arterial hemorrhage counterbalances the benefits of preventing subsequent thromboses.

Surgical ligation of the vein proximal to a thrombosis in order to prevent subsequent embolism has been attempted. After embolism has occurred, surgical removal of the offending clot may frequently save a limb if it can be achieved within six to eight hours after onset.

A promising medical treatment of thromboembolism is the early employment of a fibrinolytic or a fibrinolytic-stimulating agent that dissolves the fibrin component of the obstructing plug and permits early return of normal blood flow.

**THRONE.** A throne is the seat of a sovereign, potentate or dignitary, secular or religious, and a symbol of rule and authority.

Modern usage incorrectly applies the name to the seat alone, but historical evidence shows that not only the seat, but the dais

on which it stands and the canopy over it, forms the throne (Gr. *thronos* "elevated seat"). Thus, at the end of a papal conclave, the canopies are lowered over the throne of each cardinal except that of the newly elected pope. On occasion the dais alone is referred to as a throne; e.g., that on which two small altars were set at Louis XIII's funeral is described as a *petit trosne*. The throne cannot therefore be the forerunner of chairs, as is often supposed.

In the ancient world, particularly in the east, thrones were almost invariably of a symbolic magnificence; e.g., Solomon's throne of ivory set on a dais approached by six steps flanked by lions. On the throne of the Byzantine emperors, said to be imitated from it, the lions were mechanical, moving and emitting sounds. In the British museum, London, is a chryselephantine fragment encrusted with gold, ivory, lapis lazuli and cornelian, believed to have come from the throne of Sargon II of Assyria (722-705 B.C.).

The "Peacock Throne" of the rulers of Delhi, set with jewels and raised on a dais with silver steps, is of legendary splendour. The oldest surviving throne is probably that (much restored) built-in with the walls at Knossos (c. 1800 B.C.). The earliest remaining throne of the Christian era, the chair of St. Peter, for which Bernini created an elaborate *cathedra* in St. Peter's, Rome, is built of oak and ivory with iron carrying rings (4th-5th century). The magnificent ivory throne of Archbishop Maximian at

Ravenna dates from the following century. The so-called throne of King Dagobert from the treasury of St. Denis (now in the Bibliothèque Nationale, Paris), is a folding stool of bronze, probably 8th century but with 12th-century additions prescribed by Abbot Suger. Thrones were often of silver in the later 17th and early 18th centuries (examples at Hanover and Copenhagen); later thrones were generally of gilt wood.

The English coronation throne in Westminster abbey is more properly a ceremonial chair, and the real throne of Great Britain is the oak chair in the house of lords, used by the sovereign during the opening and prorogation of parliament. (See also CHAIR AND SOFA; CROWN AND REGALIA.)

Thrones is also the name of the third order of angels. See ANGEL. (F. J. B. W.)

**THRUSH**, the name given to any number of small to medium-sized passerine song birds comprising the family Turdidae. Many thrushes are known as the world's most exquisite songsters. Among the more famous are the nightingale (*q.v.*; *Luscinia megarhynchos*), peerless among Eurasian songsters, and the American hermit thrush (*Hylocichla guttata*), one of the finest musicians of the new world.

Thrushes range from 5 to 12 in. long, with moderate wings, bills, feet and tails. The small outermost primary, lack of distinct bristles about the gape, the fusion of the scales on the front of the tarsus into a single curved plate and the spotted plumage (at least in the young) are the commonest unifying characteristics. However, the relationships of some of the several hundred species often referred to this family are not clear, and the thrushes are not sharply separated from the old world flycatchers (family Muscicapidae).

Their plumage presents a wide range of coloration, which is often somewhat subdued and of varied patterns. One common type shown by the North American wood thrush (*H. mustelina*) and the European song thrush (*Turdus ericetorum*) is brown above and white below, with a spotted breast. Both the North American robin (*T. migratorius*) and the much smaller European robin (*Erithacus rubecula*) have a red breast (see ROBIN); whereas the eastern bluebird (*q.v.*) of North America (*Sialia sialis*) has a red breast and a blue back. The old world blackbird (*q.v.*; *T. merula*) is mostly black. Some small old world species called chats (*Saxicola*) have contrasting black and white plumage, and some Malayan whistling thrushes (*Myiophonus*) are largely dark blue with shining spangles to the tips of the feathers.

At nesting time the birds pair, and usually the female builds a cup-shaped nest of herbaceous stems and leaves, sometimes strengthened with mud. The nest is located amid the branches of a tree or shrub, in a hole in a tree, amid rocks or on the ground, depending on the species. All thrushes build open nests rather than domed ones. A clutch of three to six eggs is common, and these may be whitish or bluish, with or without spots. Typically the female incubates the eggs, and both parents help care for the young birds, feeding them insects and other invertebrates.

The thrush family is nearly cosmopolitan in distribution, but the greatest number of species are found in Europe, Asia and Africa, and a few species have colonized oceanic islands such as those of the Southwest Pacific and Tristan da Cunha. Some species are shy forest birds; some like the American and European robins are bold familiar birds of gardens and villages; others live amid the sparse brush of semiopen country or amid rocky terrain. Thrushes hop on the ground on strong legs and in the air fly swiftly, many migrating long distances. Most northern species migrate southward in winter. Some species perch freely in the open and are conspicuous, some skulk in shrubbery. Most thrushes seek insects and other invertebrates on the ground for food, but

seasonally, at least, some of the larger species feed on berries and small fruits of trees. They do not catch flying prey. Among the more unusual feeding habits is that of the song thrush. It feeds on snails by hammering them on a stone to break the shell.

**THRUSH** (PARASITIC STOMATITIS) is a disease of the mucous membrane of the mouth and throat, caused by a yeastlike fungus, *Candida* (or *Monilia*) *albicans*. It produces whitish adherent membranes on an inflamed mucosa. Often the fungus is an inhabitant of the birth canal and the mouth of the newborn infant is contaminated from there during delivery. In older children and adults the infection rarely occurs inside the mouth, more frequently in the mouth corners, causing unsightly cracks. The same fungus may invade the skin (candidiasis or moniliasis) under special circumstances. In bartenders and housewives whose hands are exposed to moisture over unduly long periods of time, the fungus causes erosions in the webs of the fingers and also may attack the nails. The skin folds of obese diabetic persons are highly susceptible to moniliasis because of moisture and high sugar content of the skin. All these localized forms can easily be cured by competent medical treatment. In emaciated undernourished persons with decreased resistance, the whole body surface may become involved. An often fatal intestinal disease of infants, acrodermatitis enteropathica, with severe diarrhea, promotes widespread monilial infection of the skin; this condition can be cured by eradicating the underlying intestinal disease.

*Candida albicans*, however, may also invade and attack the intestinal tract and internal organs. This systemic candidiasis is treated with the newer fungistatic preparations like Nystatin often in conjunction with various antibiotics. (S. Rön.; X.)

**THUCYDIDES** (fl. second half of the 5th century B.C.), greatest of Greek historians, was the author of the (incomplete) *History of the Peloponnesian War*. All that we know (perhaps all that ancient scholars knew) of his life is what he tells us himself in the course of his narrative. He was an Athenian, old enough when the war began (431 B.C.) to estimate its importance and that it was likely to be a long one, and to determine to write an account of it, observing and making notes from the beginning. He was probably born, therefore, not later than 460—perhaps a few years earlier since his detailed narrative begins with the events provocative of the war which belong to the years just before 431. He was certainly over 30 when he was elected strategos in 424 (see below). That is, he belongs to the generation younger than Herodotus. His father's name was Oloros. This is not otherwise known as an Athenian name; and Oloros was probably of Thracian descent on his mother's side, and Thucydides related in some way to the great Miltiades, who had married the daughter of a Thracian prince of this name. He himself had property in Thrace, including mining rights in the gold mines opposite the island of Thasos, and was, he tells us, a man of influence there.

He was in Athens when the great pestilence of 430–429 raged there and caught the disease himself and saw others suffer. Later in 424 he was elected one of the ten strategi of the year, and, because of his connections, given command of the fleet in the Thracian region which was based at Thasos. He failed to prevent the capture of the important city of Amphipolis by Brasidas (*q.v.*), who launched a sudden attack in the middle of winter. He was recalled and tried and sentenced to exile. This, he says later, gave him greater opportunity for undistracted study for his *History* and for travel and wider contacts, especially with the Peloponnesian side. He survived the war and his exile of 20 years ended only with the fall of Athens and the peace of 404. The time and manner of his death are uncertain, but that he died shortly after 404 is probable, and that he died by violence in the troubled times following the peace may well be true, for the *History* stops abruptly long before its appointed end. His tomb, perhaps a cenotaph, and a monument to his memory, were still to be seen in Athens in the 2nd century A.D.

**Scope and Plan of the History.**—The *History*, which is divided into eight books (probably not Thucydides' own division) stops in the middle of the events of the autumn of 411 B.C., rather more than six and a half years before the end of the war. This

ALLAN D. CRUICKSHANK FROM THE NATIONAL AUDUBON SOCIETY

WOOD THRUSH (*HYLOCICHLA MUSTELINA*) ONE OF THE FEW SONG-BIRDS THAT SINGS IN CHORDS

much at least is known: that three historians, Cratippus, a younger contemporary, Xenophon a generation later and Theopompus in the last third of the 4th century, began their histories (of Greece as a whole, for a limited period) where he had stopped, Xenophon, one might almost say, beginning the next paragraph—nearly as abruptly as Thucydides ends. From this it is certain that Thucydides' work was well known soon after publication and that no more of it was ever published than the eight books that have survived; and it may reasonably be inferred from the silence of the available sources that no separate section of the work was published in his lifetime. It may also be inferred that parts of the *History* are defective, in the sense that he would have written at greater length had he known more and that he was trying still to learn more—e.g., of internal Athenian politics in the years of "uneasy truce" (his existing narrative is in parts barely understandable without some imaginative guesswork). A good deal of the last book is defective.

We may assume, then, three fairly definable stages in his work: first, the "notes" he made of events as they occurred, always being supplemented by fresh inquiries; secondly, these notes arranged in their order and rewritten as consecutive narrative, as a "chronicle," but by no means in the final form that Thucydides intended—(e.g., some, but not all, of the story of the "uneasy truce" in book v, and, surely, most of book viii); thirdly, the final, elaborated narrative—of the preliminaries of the war (book i), of the "Ten Years' War," and of the expedition to Sicily. No documentary evidence exists of the note stage but there are passages that are only chronicle embedded in the more finished parts. Many of these, however, Thucydides intended to leave as they are. Even the most elaborated parts of the *History* may have been added to right up to his death—certainly many additions were made after the war was over.

All this is significant because Thucydides was writing what scarcely another (of eminence) has attempted, a strictly contemporary history, of events which he lived through and which succeeded each other almost throughout his adult life. Sir Winston Churchill has said of his own *Second World War*, based as it is on a unique collection of documents giving a current account of events, of the day-to-day conduct of the war: "I do not describe it as history, for that belongs to another generation. But . . . it is a contribution to history which will be of service to the future" (Introduction to vol. i, *The Gathering Storm*; Cassell and Company Ltd., 1948). Thucydides too was writing of events in some of which he took an active part, of all of which he was a direct or indirect spectator; but he attempted the final history, what, it might have been said, was "for another generation" and, as far as a man can, and as no other man has, he succeeded. It will be observed that he did not rush his work: the last of the complete narrative (stage three, above) took him to autumn 413, eight and a half years before the end of the war, the last of stage two to six and a half years before. During these last years he was observing, inquiring, writing his notes, adding to or modifying what he had already written; at no time before the end, during all the 27 years of the war, did he know what that end would be (unlike Churchill in this), nor therefore what would be the length and the final shape of his own *History*. It is evident that he did not long survive the war since he did not leave any connected account, even at stage two, of the last six years. But, in what he lived to complete, he wrote a history, not a contribution to history.

It should however here be stated that in the opinion of some scholars (see BIBLIOGRAPHY), Thucydides did wait till after 404 to compose his *History* from his accumulated notes; and that much of the earlier part, especially Pericles' speeches in book ii, is only to be fully understood in the light of the final defeat of Athens. He was of course, as stated, always thinking about and sometimes modifying what he had already written; but the view that he, in any real sense, "began" his work after 404 seems to be untenable.

**Diagnosis of the Causes of the Peloponnesian War.**—The conflict which he set out to describe, in detail, as truthfully as possible, with strict observation of the chronology was, as he saw it, twofold. In its simpler aspect it was caused by the rapid rise of

Athens in wealth and political power after the Persian Wars, which was a challenge to the generations-old Spartan leadership in Greece. This leadership was traditional and had been widely accepted—so much so that in 480 Athens, in spite of a sharp conflict with Sparta over its internal affairs 30 years before and its proud consciousness that it had stood alone, and successfully, at Marathon in 490, was ready to accept it, with all the other Greek states who shared in the resistance to the second Persian invasion (see GRECO-PERSIAN WARS).

In 431 Sparta, though "ever slow in going to war," took up the challenge and declared war. But Athenian power was something more than that of an ambitious rival. To the Greek world, accustomed as it was to the autonomy of cities under democratic rule, and even to the Athenians themselves at times, it appeared "like a tyranny"—moderately used as they asserted, contrary to all Greek custom as their enemies said. It had begun in Athens' chosen leadership of the Delian league in which a number of Greek states were bound together for common defense against a further Persian attack. They had taken an oath not to secede from this league; but a few did—some of the larger ones who were also geographically safer from Persian menaces—and Athens, followed by the rest, reduced them to subjection. One or two others, originally outside, were forced in. Most of the states contributed money for the league, the amount from each being decided by Athens (moderately enough); the common treasury was transferred to Athens and Athenian officers controlled it. Athens encouraged, and sometimes imposed, the adoption of its own kind of democracy in recalcitrant cities and made, sensibly enough, or tried to make, its own excellent coinage common for all in the league, to the great advantage of trade. By arranging that delegates conveying the tribute should come there for the most important of the dramatic festivals, and in other ways, Athenians encouraged all to look upon their city as a religious and intellectual centre (the latter it had already, by its own radiant genius, become). All this attempt at unity under one leadership was new in Greece and dangerous, both to the influence of Sparta and to Greek political institutions; and Thucydides makes this clear, and why general opinion in Greece favoured the Peloponnesian cause. But he also makes clear that Athenian rule was no "empire" in any ordinary sense (Persian, Roman or modern)—not only were there no "provinces" with Athenian governors to administer them, because each state was individually attached to Athens, but free institutions in them survived and were active, and indeed the commons in most were favourable to Athens, or at least preferred its rule to the risk of seeing their own richer classes put in power by Sparta.

**Character Studies of the Leading Participants.**—There was another aspect of the conflict which interested Thucydides and which he emphasizes: it was also between the ever-active, innovating, revolutionary, disturbing Athenians and the slower-moving, more cautious Peloponnesians, especially the Spartans, "not excited by success nor despairing in misfortune," but quietly self-confident. This was a conflict between two types of character; but also it in some degree crossed the conflict between states. Thucydides was not much concerned with individuals, rather with the actions and sufferings, the characters of states ("the Athenians," "the Syracusans," etc.); but he understood the significance of personalities, and besides making clear by their words and deeds the characters of some who influenced events, as Cleon the harsh demagogue of Athens and Hermocrates the would-be moderate leader in Syracuse, the brave Nicias and the incompetent Alcidas, he goes out of his way to make clear the characters and influence of four men: Themistocles (in a digression, the Athenian hero of the second Persian War), Pericles, Brasidas and Alcibiades (qq.v.). All four of them were of the active, revolutionary type—Pericles indeed was unique for Thucydides in that he combined caution and moderation in action, and great stability of character with a daring imagination and intellect; but he was a leader of the new age. During the war each of them—Pericles and Alcibiades in Athens, Brasidas in Sparta—was in conflict with a conservative, quietist opposition; and one expression of this in Thucydides deserves especial notice. Pericles, trying to restore the confidence of the Athenians struck down with the pestilence, told them that

risk and labour were unavoidable by an imperial city—"quietism" was only for those who sought security in servitude—and that even in defeat they would leave behind an imperishable name. Nicias the cautious, on the other hand, is described as believing that he could save his name by taking no risks and that to make peace meant to take no risk. In Sparta it was the wise and strong King Archidamus who led at first the cautious and conservative side, Brasidas the other; and Brasidas had his enemies at home. The conflict between the revolutionary and the conservative thus ran across that between the (on the whole) daring Athenians and the (on the whole) cautious Peloponnesians; and it is a great loss that Thucydides did not live to write the story of the last years of the war when Lysander (*q.v.*), the other great revolutionary Spartan, played a larger part than any other single man in the defeat of Athens. This defeat was in one aspect the defeat of intellectual brilliance and daring by "stupidity" and stability of character (this last the quality most lacking in Alcibiades, the most brilliant Athenian of the second half of the war); but it was largely brought about by the two Spartans who rivaled Athenians in daring and intellect.

**Study of the Technical Aspects of the War.**—There is another aspect of the war in which Thucydides was much interested—the technical. One problem was the limitations of normal Greek heavy-armed land fighting, conducted mainly by peasant farmers who could not long be away from their fields or the harvest would be ruined, against other peasant farmers who must defend their fields to prevent a destruction of the crops which might mean near starvation. There was the special case of Sparta, which was free of these limitations because it had helots for its agriculture; the citizens also had time for harder training and for longer warfare. A quite different case was that of Athens, which could if necessary bring all the population behind walls, sacrificing the highly developed fields and farms of Attica. Athens could import all the food needed, because it was powerful at sea and rich enough by silver mines, manufacture and trade and by accumulated capital to pay for the import. Other problems concerned the difficulties and possibilities of war between an all-powerful land force (Sparta and its allies) and an all-powerful navy; many of these were peculiar to the conditions of Greece and the Mediterranean at that time, but some endured to modern times. Thucydides studied the details of siege warfare; the difficulties of the heavy-armed in mountain country or of the Greeks fighting the fierce but unruly barbarians of the north; an army trying to force a landing from ships against troops on shore; the one great night battle, at Syracuse; the skill and the daring maneuvers of the Athenian sailor and the way these were overcome by the Syracusans; the unexpected recovery of the Athenian fleet after the Sicilian disaster. In all these aspects of the war he took a keen professional interest.

This is too the reason why in Thucydides' introductory pages on the early history of Greece he lays so much stress on the development of sea trading and naval power and on the accumulation of capital resources: they help to explain the great war between a land power and a sea power.

**Thucydides' Style.**—Thucydides himself of course was an intellectual of the Athenian kind; markedly individualist as he was, his whole style shows the man brought up in the company of Sophocles and Euripides, with Anaxagoras, Socrates and the contemporary sophists.

Of this style something should be said here, and the analysis given by R. C. Jebb in the article on Thucydides in the 9th edition of *Encyclopædia Britannica* (1888) cannot be bettered. Jebb begins by contrasting the styles of Antiphon (*q.v.*), said, very improbably, to have been Thucydides' master, and of Thucydides himself:

Antiphon wrote for hearers, Thucydides for readers; the latter, consequently, can use a degree of condensation and a freedom in the arrangement of words which would have been hardly possible for the former. Again, the thought of Thucydides is often more complex than any which Antiphon undertook to interpret; and the greater intricacy of the historian's style exhibits the endeavour to express each thought. Few things in the history of literary prose are more interesting than to watch that vigorous mind in its struggle to mould a language of magnificent but immature capabilities. The obscurity with which Thucy-

des has sometimes been reproached often arises from the very clearness with which a complex idea is present to his mind, and his strenuous effort to present it in its entirety, . . . He never sacrifices the thought to the language, but he will sometimes sacrifice the language to the thought. A student of Thucydides may always be consoled by the reflexion that he is not engaged in unravelling a mere rhetorical tangle. Every light on the sense will be a light on the words; and when, as is not seldom the case, Thucydides comes victoriously out of this struggle of thought and language, having achieved perfect expression of his meaning in a sufficiently lucid form, then his style rises to an intellectual brilliancy—thoroughly manly, and also penetrated with intense feeling—which nothing in Greek prose literature surpasses.

**Method, Aims and Authority as an Historian.**—In a prefatory note near the beginning of the *History* Thucydides speaks a little of the nature and difficulties of his task and of his aims. It was difficult, he says, to get at the truth both of the speeches made, whether he heard them himself or got the report from others, and of the actions of the war. For the latter, both for those at which he had been present and for the others, he made as thorough an enquiry as he could—for eyewitnesses did not always say the same things, either from faulty memory or from bias. For the speeches, he says, in order to meet the difficulties, he had written out in his own words what was appropriate to the occasion, keeping as closely as possible to the general sense of what had actually been said. He could not do without speeches, for it is through them that he explains the motives and ambitions whether of leading men or of states; and this, the study of the human mind in time of war, is one of his principal aims. (The omission of speeches from the last book is a great loss and is due, no doubt, to the difficulty he had in getting information about Athens at this period.) They are reported in direct speech though in Thucydides' own words, in his own unique style, partly because he must not pretend that they were exact reports, partly because long passages in indirect speech would be scarcely tolerable and no more "authentic." He avoided, he says, all "storytelling" (this is his one criticism of Herodotus), and his work might be the less attractive in consequence; "but I have written not for immediate applause but for posterity, and I shall be content if the future student of these events, or of other similar events which are likely in human nature to occur in after ages, finds my narrative of them useful." This is all that he expressly tells us of his aim and methods. Moreover in the course of his narrative (except for the pestilence of 430 and his command in 424) he nowhere gives his authority for a statement: neither which speeches he had heard nor the other campaigns he had taken part in, nor what places he had visited, nor what persons he consulted. He insisted, as Gilbert Murray said, in doing all the work himself; and he gives us, for the parts he completed, the finished structure, not the plans and the consultations as well, not the "scaffolding."

His authority is hardly equaled by that of any other historian. He kept to a strict chronological scheme, and where it can be accurately tested, *e.g.*, by the eclipses that he mentions, it fits closely. There are also a fair number of contemporary documents recorded on stone which almost all confirm his account in general and in detail. There is the silent testimony of the three historians who began where he left off, not attempting, in spite of much independence of opinion, to revise what he had already done, not even the last book which he clearly did not complete (it is here that occurs the one serious divergence from him in a later writer—Aristotle; *see below*). Another historian, Philistus (*q.v.*), a Syracusan who was in Syracuse as a boy during the Athenian siege, had, it seems, in his *History of Sicily*, little to alter or to add to Thucydides. Above all there are the contemporary political comedies of Aristophanes (the production dates of which are fortunately known). Aristophanes (*q.v.*) was about 15 years younger than Thucydides and a man of as different a temper and writing with as different a purpose as could well be, but his comedy remarkably reinforces the reliability of the historian's serious picture of Athens at war, and as well supplies much to this picture of a kind which Thucydides deliberately did not give. The modern historian of this war is in much the same position as the ancient: he cannot do much more than translate, abridge or enlarge upon Thucydides.

For he kept rigidly to his theme, the history of a war, that is, a story of battles and sieges, and of a truce or a peace and alliance

hastily made and soon broken, but also, more important, of the behaviour of peoples as the war lasted longer and longer, and of the inevitable "corrosion of the human spirit." He has vivid narrative of exciting episodes and careful descriptions of tactics on land and sea. He gives a picture, direct in speeches, indirect in the narrative, of the ambitious imperialism of Athens—controlled ambition in Pericles, reckless in Alcibiades, debased in Cleon—ever confident that nothing was impossible for them, resilient after the worst disaster; and the opposing picture of the slow steadiness of Sparta, sometimes so successful, at others so accommodating to the enemy. The speech he records of Pericles on those killed in the first year of the war is the most glowing account of Athens and its democracy as its leading citizen hoped it might prove itself. It is followed (in of course due chronological order) by a minutely accurate account of the symptoms of the pestilence ("so that it may be recognised by medical men if it recurs") and a moving description of the demoralizing despair which took men after so much suffering and such heavy losses—probably more than a quarter of the population, most of it crowded within the walls, died. Equally moving is the account of the last battles in Syracuse harbour, and of the Athenian retreat. In one of his best-known passages he analyzes by a most careful choice of words, almost creating the necessary language as he writes, the effects, moral as well as political, of civil strife within a state in time of war. By a different method, in speeches, he portrays the hard fate of Plataea due to the long-embittered envy and cruelty of Thebes and the faithlessness of Sparta, the harsh brutality of Cleon against Mytilene and the cynicism of the Athenians at Melos 12 years later, when the premises that it is in human nature for the strong to dominate the weak, and that Athens must for its safety control all islands, are used to justify any aggression and a demand for immediate submission, and slaughter if submission is not immediate. Occasionally he is forced into personal comment, as on the pathetic fate of the virtuous and much liked Nicias.

He had the strongest feelings, as a man, as a citizen of Athens whose part was the largest in the tragedy that he recorded, above all in his passion for the truth as he saw it, which not only kept him free from vulgar partiality against the enemy, whether state or party, but served him as a historian in the accurate narrative of events, accurate not only in their detail and their order, but in their relative importance—he does not for example exaggerate the importance of the campaign in which he was himself in command. That is why he offers no self-defense for his failure. (Characteristically he mentions his exile not in its order as an event of the war, but in his "second preface"—after the peace of 421—to explain his opportunities of wider contacts.)

**Subsequent Fame.**—The story of his later fame is a curious one. It has been mentioned above that in the two generations after his death three historians began their work where he had left off; but apart from this silent tribute and late stories, credible enough, of his great influence on the orator Demosthenes (*q.v.*), Thucydides is nowhere referred to in surviving 4th-century literature, not even in Aristotle, who, in his *Constitution of Athens*, gives a narrative of the revolution in Athens in 411 that diverges in many ways from that of Thucydides. It was not till the end of the 4th century that Theophrastus coupled him with Herodotus as a founder of history properly so-called. We know little of what the scholars of Alexandria and Pergamon did for his book; but copies of it were being made in considerable numbers in Egypt, and so doubtless more elsewhere, from the 1st to the 5th centuries A.D. Suffice it to say, that by the 1st century B.C. as is clear from the writings of Cicero and Dionysius (who vainly disputed his pre-eminence), Thucydides was established as the great historian, and from that time onward his fame has been secure wherever he has been known.

**BIBLIOGRAPHY.**—*Texts*: "Oxford Classical Series," by H. Stuart Jones and J. E. Powell, 2 vol. (1953–55); "Teubner Series," by C. Hude, editio major (1901), new ed. by O. Luchnat (1954–); in "Bude Series," by Jacqueline de Romilly, with French trans. (1953–).

*Commentaries*: That of T. Arnold (3 vol., 4th ed., 1857) is still worth consulting; important for the interpretation of language are J. M. Stahl's ed. (in Latin, 1882–88) and that of J. Classen, rev. by J. Steup

(1900–22); for books i–ii only, A. Croiset (1886). See also A. W. Gomme's *Historical Commentary* (1945–).

*English Translations*: That of Thomas Hobbes (1629), is well worth reading. Modern translations include an accurate and vigorous translation by R. Crawley (1876; in Everyman's Library, 1910, and reprinted in *Great Books of the Western World* [1952], vol. 6); and a lively one by Rex Warner (1954).

*Studies and Special Aspects*: R. C. Jebb, *Attic Orators*, vol. i (1876); G. B. Grundy, *Thucydides and the History of His Age* (1911); E. Schwartz, *Das Geschichtswerk des Thukydides* (1919); J. H. Finley, Jr., *Thucydides* (1942), the best case for the view that Thucydides wrote all his *History* after 404 (see above); A. W. Gomme, *Essays in Greek History and Literature* (1937) and *Greek Attitude to Poetry and History* (1954); J. de Romilly, *Thucydide et l'imperialisme athénien* (1947) and *Histoire et raison chez Thucydide* (1956).

(A. W. GE.)

**THUCYDIDES** (5th century B.C.), son of Melesias (and usually so called to distinguish him from the historian), Athenian politician, took over the leadership of the opposition to radical democracy on the death of Cimon (450), to whom he was related, perhaps as brother-in-law. He protested against the use on Athenian temples of the large reserve of contributed money accumulated by the Delian League (*q.v.*), and he fought the principle of extending state pay, which was likely to consolidate the power of the masses. His father had been a famous wrestling master and from him Thucydides inherited wide connections outside Athens. Like Cimon before him, he preferred to keep the people in their place and not to sharpen the differences between Sparta and Athens. To achieve his ends he was not scrupulous about means and organized his supporters to sit together in the assembly to make their protests more noisy and effective. His opposition, stubborn and continuous, was ended by his ostracism in 443. After ten years he returned to Athens but was no longer effective. He died soon after 431. See also PERICLES.

(R. ME.)

**THUG** (THAG; Sanskrit *sthaḡ*, "to conceal," hence *sthaḡa*, "a cheat"), a member of a well-organized confederacy of professional assassins who for more than 300 years traveled in gangs through India, wormed themselves into the confidence of wayfarers and, when a favourable opportunity occurred, strangled them by throwing a handkerchief or noose round their necks, and then plundered and buried them. All this was done according to certain ancient and rigidly prescribed forms and after the performance of special religious rites, in which the consecration of the pickax and the sacrifice of sugar formed a prominent part. From their using the noose they were also frequently called *phansigars*, or "noose operators." Though they themselves traced their origin to seven Muslim tribes, Hindus appear to have been associated with them at an early period; at any rate, their religious creed and practices as worshippers of Kali (Devi, Durga), the Hindu goddess of destruction, had certainly no flavour of Islam. The fraternity possessed a jargon of its own (*Ramasi*) and signs by which its members recognized each other.

Though sporadic efforts were made toward the extinction of the gangs, it was not till Lord William Bentinck (governor general of India, 1828–35) took vigorous steps that the system was seriously attacked. His chief agent, Captain (afterward Sir William) Sleeman, with the cooperation of the authorities in a number of princely states, succeeded so well in grappling with the evil that between 1831 and 1837 no fewer than 3,266 thugs had been committed, of whom 412 were hanged, 483 admitted as approvers, and the remainder transported or imprisoned for life.

According to the *Thuggee and Dacoity Report* for 1879, registered Punjabi and Hindustani thugs then still numbered 344; but all of these had already been registered as such before 1852, and the whole fraternity thereafter became extinct.

Sleeman, *Ramaseena, or a Vocabulary of the Peculiar Language used by the Thugs, with an Introduction and Appendix* (1836) and *Rambles and Recollections of an Indian Official*, rev. ed. by V. A. Smith (1915); P. Meadows Taylor, *Confessions of a Thug*, rev. ed. (1916); R. V. Russell and Hira Lal, *The Tribes and Castes of the Central Provinces of India*, vol. iv (1916).

**THULE**, the Greek and Roman name for the most northerly land in the world. Pytheas (c. 300 B.C.) heard of and perhaps even reached it, six days' sail from Britain; it was inhabited, but

grain grew there sparingly and ripened ill; the nights were extraordinarily long and/or bright. Nearby was the "sluggish" sea, "neither land, nor sea, nor air" (possibly a North Sea fog). The few surviving fragments of Pytheas' works do not determine where his Thule was. Scholars at various times have believed it to be the Shetlands, Iceland, or some section of the Norwegian coastline (Thule in Greenland is a modern name).

Agricola's fleet, sailing up the east coast of Scotland in A.D. 83 or 84, is said to have seen but not to have reached Thule (*dispecta est Thule*), but the phrase is probably a literary reminiscence by Tacitus. The actual point meant may be the Orkneys or the Shetlands, or even some fragment of Scotland seen across the water. In some later writers (Procopius, etc.) Thule seems sometimes used to denote Scandinavia. Virgil's phrase "ultima Thule" is commonly used to describe the farthest limit possible.

**THULIUM** is a metallic element of the rare-earth group, symbol Tm, atomic number 69, and atomic weight 168.934. There is only one naturally occurring stable isotope, Tm<sup>169</sup>; when it is bombarded by neutrons a radioactive isotope Tm<sup>170</sup> is formed. This isotope has a half life of 125 days and emits a soft gamma radiation of 0.084 Mev that resembles X radiation. It is useful in small portable X-ray units suitable for photographing bony tissues, for examining thin-walled machine parts, and has been used by archaeologists to examine markings and symbols on ancient metal artifacts. Thulium was discovered by P. T. Cleve (1879), who named the oxide thulia for the Thule (*g.v.*) of the ancient Greeks and Romans, representing a remote goal or end. It is the least abundant of the rare-earth metals and is found in very small concentrations in such minerals as gadolinite, euxenite, xenotime, and samarskite. It also occurs in the products of atomic fission and is produced commercially by ion exchange (*g.v.*).

Although there is evidence that thulium can exist in the divalent state, the only definitely established oxidation state is plus three, both in solid compounds and in solution. Thulium behaves as a typical rare earth, forming a series of pale-green trivalent salts. Solutions on the Tm<sup>3+</sup> ion are faintly green and exhibit sharp absorption bands in the ultraviolet and visible regions (*see SPECTROCHEMICAL ANALYSIS*). The presence of unpaired electrons makes the ion strongly paramagnetic; its radius is 0.869 Å and the thermal neutron cross section is 118 barns. Thulium metal has been prepared by thermoreduction of the anhydrous fluoride with calcium metal. The metal is readily oxidized by air or by water; melting point is 1545° C; the density of the hexagonal close-packed structure is 9.332 g. per cc. The metal is ferromagnetic below about -263° C. *See also RARE EARTHS.*

*See N. E. Topp, The Chemistry of the Rare Earth Elements (1965). (Ld. B. A.; J. B. Ps.)*

**THUN**, a town in Bern canton, Switzerland, and capital of the Bernese Oberland, lies on the Aare River, at the point where it issues from the Lake of Thun, and is 17 mi. (27 km.) SSE of Bern by rail. Pop. (1960) 29,034. The Lake of Thun is 11½ mi. (19 km.) long, 2 mi. (3 km.) wide; its area is 18½ sq.mi. (48 sq.km.). Its maximum depth is 712 ft. (217 m.), and its altitude is 1,831 ft. (558 m.). With the Lake of Brienz it occupies the ancient terminal basin of the Aare Glacier.

The town was founded in the 12th century and belonged to the kingdom of Burgundy until 1323 when it fell to the city state of Bern. Part of the medieval town still remains: the Zähringen-Kyburg Castle (tower 1186-91, living quarters 1432; now a museum), the Protestant church (Romanesque-Gothic tower), and the town hall (1585) are the finest buildings of the old part. Noteworthy is the church of Scherzigen (dating from about 1000; on the left bank), with fine frescoes. The town produces cheese, machinery, and pottery. (R. O. H.)

**THUNDERSTORM**, a violent atmospheric disturbance characterized by a large cumulus cloud in which localized centres of electric charge have developed. Lightning, and the accompanying thunder from which the storm derives its name, represent a spark discharge between these centres, or between one of them and the ground. So universal is the development of charge centres in large intense cumulus clouds that the term "thunderhead" is used to describe a large cumulus even though the physical processes which

lead to the development of the convective cloud may be only indirectly related to the processes which bring about the lightning and thunder.

Thunderstorms are sometimes referred to as "weather factories" because they are accompanied by a wide variety of weather elements such as hail, showery rain, strong and gusty winds and sudden temperature changes at the earth's surface. The violence of the weather accompanying thunderstorms is indicative of the strong vertical air currents and the complex physical processes operating within them.

Cumulus clouds are manifestations of convective overturning in the atmosphere; *i.e.*, a cumulus cloud represents an air parcel which is rising through its environment because it is warmer and more buoyant than other air parcels at the same levels. In principle, this overturning is similar to that in any thermally unstable fluid. When the atmosphere becomes sufficiently unstable, convective overturning is locally severe enough to cause thunderstorm development.

**Thunderstorm Structure and Circulation.**—The average thunderstorm consists of three to five convective cells, each of which undergoes a life cycle characterized by changes in the direction and magnitude of the strong nearly vertical air currents. Three stages in this life cycle are recognized. In the initial stage, the cell contains strong upward-moving air currents which extend from below the cloud base to the cloud top. The updrafts may reach speeds of seven to ten metres per second. If the air is sufficiently unstable, there will be a continual supply of energy for the updraft and the cell will continue to develop in size and intensity. With increase in size comes an increase in total cloud water content. About 15 to 20 minutes after the establishment of an active updraft, precipitation particles will have grown to a size where they become of importance both in the further development of the cell and in the formation of the charge centres. The precipitation usually will be in the form of snow and snow pellets in the upper parts of the cell (colder than about -5° C.) and raindrops in the lower, warmer regions of the cell. At this time the cell passes into the mature stage of development.

In the mature stage of development, both upward- and downward-moving air currents are present within the cell. The updraft of the cumulus stage gives way to downdraft as the size and number of precipitation particles increase. This reversal of the updraft is also aided by evaporational cooling which occurs as clear air from outside the cloud is mixed into the cloud by the turbulent motions. At first, the downdraft is small and located on one side of the updraft. Gradually, however, it works its way across the cell and squeezes off the updraft, at which time the cell goes into the final or dissipating stage.

It is with cells in the early mature stage that thunderstorms reach their greatest violence. Updraft speeds are usually 10 to 15 m. per second, but may occasionally reach values as high as 35 m. per second. Downdrafts may be as strong as 15 m. per second. At the ground, the onset of heavy rain marks the beginning of the mature stage. The downdraft, which coincides closely with the rain area, reaches the surface a few minutes after the first rain. Because of the continued evaporation, air in the downdraft is cold, which fact accounts for its great downward speed. As the downdraft nears the ground, it is diverted and spreads outward in all directions as a cold gusty wind blowing from the rain area. Even in arid regions where the rain may completely evaporate before reaching the ground, the cold downdraft spreading over the surface is a well-known signal of a nearby thunderstorm.

A thunderstorm cell in the dissipating stage is filled throughout by weak subsiding air and light precipitation. Rain at the earth's surface is much less intense than was the case during the mature stage. The cold outflow gradually subsides as a result of the waning downdraft.

The visual appearance of thunderstorms varies greatly from place to place and with kinds of storms. In arid regions, thunderstorms appear as giant towering cumulus clouds, standing in bold relief against the clear blue sky. Frequently in such regions one can see the uppermost parts of the cloud carried off by high winds to form what is known as an anvil top. In other more humid

regions, thunderstorms are frequently surrounded by smaller clouds which obscure the active parts of the storm to a ground observer. From an airplane, however, one can see the thunderstorm thrusting upward above the lower clouds.

The time duration of a thunderstorm is somewhat variable; however, observations show that the first two stages of development usually last about 15 to 20 minutes each. During these stages the visual cloud will frequently reach heights of 30,000 to 60,000 ft. (9,000 to 18,000 m.) and average about 40,000 ft. (12,000 m.), and horizontal dimensions of several miles. The duration of a cell in the final stage varies over wide limits. Some storms end abruptly, whereas others may linger for several hours as a gentle rain from a large, formless cloud mass. These differences result from differing conditions of the air masses in which the clouds form.

**Thunderstorm Electricity.**—Electrical charge centres become well established during the mature stage. Lightning is a crash discharge between an upper positive centre and a lower negative centre or between one of these and the ground. Occasionally one also observes a lightning flash from one of the centres into the clear air around or above the cloud. The first electrical discharges usually take place entirely within the cloud between the two main charge centres. These discharges will be rather small at first and will increase in magnitude as the storm continues to develop. Each lightning flash usually consists of several strokes in rapid sequence with time separations of a few hundredths of a second. Each stroke follows the ionized path of the preceding one.

The sound of thunder originates in a compression wave formed along the highly heated path of the lightning stroke. Each portion of the path of a lightning stroke sends out intense sound waves which travel different paths to the observer. Since sound travels at the rate of approximately 330 m. per second, and since the strokes may be several kilometres in length, the thunder is usually heard as a drawn-out rumbling, having character and time duration depending upon the length and shape of the flash and upon its distance from the observer. For detailed discussion of thunderstorm electrification see **LIGHTNING**, especially *Propagation of Lightning* and *Effects of Lightning: Thunder*.

**Thunderstorm Formation.**—A deep layer of moist air and a vertical temperature distribution favourable for the development of intense local overturning are essential for thunderstorm development. One of the tools used by meteorologists to determine the possibilities for thunderstorms is a plot of air temperature as a function of height above the earth's surface. The rate of decrease of temperature with height is known as the lapse rate. In general, steep lapse rates (rapid decrease of temperature with height) are most favourable for thunderstorms since it is under these conditions that an air parcel made warmer than its environment is capable of rising through the atmosphere because of buoyancy forces. After any given parcel of air is lifted to the point of condensation at the cloud base, the released latent heat of condensation will be added to the parcel. This will assist further ascent. In the upper parts of the thundercloud, where snow and ice crystals are found, the latent heat of fusion will also contribute to sustaining the updraft currents.

Thunderstorms can be classified according to factors that contribute to the development of steep lapse rate with resultant convection. Five important classes are given:

1. Heating of air by contact with warm surfaces. (a) When the surface of the ground is warmed by radiation from the sun, water vapour may be carried up by convection currents to a level at which condensation occurs. With favourable lapse rates of temperature in the air above this level, thunderstorms may develop. A special case of this class is the heating of mountain slopes at high levels, which frequently contributes to the development of thunderstorms near the summits. (b) When air flows over warmer ground or warmer water, the air may become warmed sufficiently from below for convection and possibly thunderstorms to occur.

2. Lifting of warm air over cold currents. If a current of cold air meets a current of warm air, the warmer air, being lighter, is forced upward either by cold air underrunning warm air or by warm air overrunning cold air. Clouds form in the rising warm

air, and if conditions are favourable, tower upward to form thunderstorms.

3. Converging air flow within warm air currents. A converging flow may force warm air up to its condensation level, releasing convection.

4. Interaction of cold and warm air currents at different levels. The underrunning of cold air by warm air may initiate convection. Similarly, overrunning of warm air by colder air as well as combinations of these factors may be effective in releasing convective overturning and thunderstorms.

5. Lifting of air by movement upslope from lower to higher ground. Movement of air against a mountain range or other upslope surface may lift air to its condensation level and initiate convection.

**The Distribution of Thunderstorms.**—A substantial fraction of the thunderstorms over the world form because of surface heating by sun's radiation (class 1a) often combined with special convergence effects (class 3). Summer thunderstorms over humid continents and over mountain regions in the temperate latitudes and the almost daily storms of large regions of the tropics are of this type. These storms show a well-marked diurnal variation; they develop generally during the afternoon. Storms of class 1b are characteristic of the rear of barometric depressions occurring over the sea in winter especially off the east coasts of large continents where cold air may pass over comparatively warm water.

The "frontal" storms of class 2 are found in middle latitudes. They are associated with line squalls (squall lines) and "warm front" precipitation in extratropical cyclones.

Storms of classes 3 and 4 frequently occur in advance of "cold fronts" or troughs of low pressure in the temperate zone and tend to occur more frequently at night than during the day.

Storms of class 5 occur especially on windward mountain slopes in middle latitudes.

Thunderstorms have been known to occur in almost every part of the world; however, they are rare in the polar regions and infrequent poleward of latitude 50° N. and 50° S. According to a study by C. E. P. Brooks, the places of maximum thunderstorm activity in the world are Java (225 days per year), central Africa (150), Panama (135), southern Mexico (142) and central Brazil (106). In the United States the areas of maximum activity are the Florida peninsula and the coast of the Gulf of Mexico (70–80) and the mountains of New Mexico (50–60). Central Europe and Asia average less than 20 thunderstorm days per year. Brooks estimated that at any one moment there are about 1,800 thunderstorms in progress throughout the world.

**Thunderstorms and Severe Weather.**—Thunderstorms are associated with many kinds of severe weather phenomenon. Squall lines are lines of thunderstorms which sweep across the surface as a single unit. Usually associated with advancing cold fronts, squall lines are well known for their regions of high wind, heavy rain and hail. Tornadoes are another type of severe weather associated with thunderstorms although the exact details of this association are not known.

Thunderstorms also play a key role in tropical hurricanes. It is well known that hurricanes, when viewed by radar, are characterized by lines of convective storms which spiral inward toward the eye of the hurricane. It is likely that the thunderstorm plays a major role in the vertical circulation of the hurricane.

Because of the turbulence which accompanies the updrafts and downdrafts, thunderstorms are regarded as hazards to airplane flight. Pilots are unanimous in their opinion that light planes should not be flown into thunderstorms. Military and commercial planes are sufficiently sturdy and well enough instrumented to permit a flight through a thunderstorm with little more danger than passenger discomfort.

See also **LIGHTNING**; **SQUALL** AND **SQUALL LINE**; **TROPICAL STORM**; **TYPHOON**; and references under "Thunderstorm" in the Index.

**THÜNEN, JOHANN HEINRICH VON** (1783-1850), German agriculturalist, best known for a pioneering work on the effect of transportation costs on the location of production, was born in Jever on July 24, 1783. Vol. 1 of his *Der isolierte Staat*, containing the important theoretical contribution, appeared in 1826, and later volumes presented Thünen's own agricultural accounts in support of his theory. Thünen imagined an isolated city, set in the middle of a level and uniformly fertile plain without navigable waterways and bounded by a wilderness. His analysis showed how agricultural products would be grown in zones forming concentric rings around the city. Heavy products, in proportion to value, and perishables would be produced close to the town; lighter and durable goods would be produced on the periphery. As transport costs to the city increased with distance, the returns to the land would diminish. At a certain distance from the city, land rent would become zero. The exact distance would be a function of price relationships. Moreover, if land rents vary, then the methods of cultivation will vary, with land being used less intensively as it becomes less valuable. Subsequent writers often built upon Thünen's model, although his simplifying assumptions eliminated many of the most critical problems. Thünen died in Tellow, Sept. 22, 1850. (J. P. CA.)

**THUN-HOHENSTEIN**, the name of a German noble family, recorded in the southern Tirol as early as A.D. 1145 but associated with Bohemia from 1627.

**FRIEDRICH, GRAF VON THUN-HOHENSTEIN** (1810-1881), was born at Tetschen (Decin) on May 8, 1810. A member of the Austrian diplomatic service, he was sent in 1850 to preside over the revived German federal diet at Frankfurt, chiefly with the aim of resisting Prussia. Having been minister to Prussia (1852-54) and to Russia (1859-63), he left the diplomatic service and concerned himself with Bohemian and Austrian internal politics, following his brother's example. He died at Tetschen on Sept. 24, 1881.

**LEO, GRAF VON THUN-HOHENSTEIN** (1811-1888), was born at Tetschen on April 7, 1811, a younger brother of Friedrich. Influenced by the Romantic movement and by the Catholic revival and sympathetic to the aspirations of the Czechs as expounded by Frantisek Palacky, he wanted to see a resurrection of the "historic nations" of the Habsburg state, namely the Hungarians, the Poles and the Bohemians, so that they could play a greater part in affairs beside the Germans (*see AUSTRIA, EMPIRE OF*, for the background of his career; also *BOHEMIA*). In the revolutionary year 1848 he was appointed governor of Bohemia in April but fell into the insurgents' hands and had to give up his post when order was restored (July). From 1849 to 1860, however, he was Austrian minister for religious affairs and education. He established that instruction in the primary schools should be in the regional language, though German remained the language for higher instruction; he summoned capable German scholars, Protestant as well as Catholic, to improve the standard of teaching; and he encouraged the formation of learned societies. The concordat of 1855 between Austria and the papacy was however regarded by liberals as detracting from his achievement in the educational field, though in practice it did not lead to so much clerical interference with teaching as had been foreseen. Out of office from 1861, Leo von Thun opposed the "February patent" of that year and stood as a leader of the "Feudal" party of Bohemian noblemen supporting the movement for a federal organization of the Habsburg dominions. He accordingly opposed the Austro-Hungarian "Compromise" of 1867 because it was to the disadvantage of the Slavs; and he played a part in the abortive negotiations of 1871 between Vienna and the Czechs. He died in Vienna on Dec. 17, 1888.

**FRANZ ANTON, GRAF and, from 1911, PRINCE VON THUN-HOHENSTEIN** (1847-1916), was Friedrich's son, born at Tetschen on Sept. 2, 1847. Adhering to his uncle's views, he was made gov-

ernor of Bohemia in 1889. The Young Czechs agitated against the settlement of 1890 (agreeable to Thun's conservatism) between the Old Czech party and Vienna, and he suppressed disorders firmly, but he resigned in 1895. He became prime minister of Austria in March 1898 but fell from power in October 1899 when the Germans objected to his policy on the language question. Governor of Bohemia again from 1911 to 1915, he died at Tetschen on Nov. 1, 1916.

**THURBER, JAMES GROVER** (1894-1961), writer and artist, considered by many the best American humourist since Mark Twain, was born in Columbus, O., Dec. 8, 1894, and edu-

(LEFT) JAMES THURBER. PHOTO. GRAPHED IN 1959; (ABOVE) HIS CARTOON "ALL RIGHT, HAVE IT YOUR WAY — YOU HEARD A SEAL BARK" (LEFT) HENRI-CARTIER-BRESSON—MAGNUM; (ABOVE) COPR. © 1982, 1960 JAMES THURBER FROM "THE SEAL IN THE BEDROOM" PUBLISHED BY HARPER AND ROW

cated at its public schools and at Ohio State university, Columbus. He was a newspaper reporter in Columbus, in Paris, France, and in New York city before becoming associated with the *New Yorker* as a staff member (1927-33) and a leading contributor.

Seriously a writer and only incidentally a comic artist, Thurber produced both writings and drawings showing odd characters in astonishing situations, amusing aspects of the war between men and women, startling forays into the subconscious and fascinating dogs and other animals, real and imaginary.

His writings reveal a sensitive literary style and skill in many forms. *My Life and Hard Times* (1933) is a hilarious autobiography. "The Secret Life of Walter Mitty," his best-known short story, presents an unforgettable character in the meek, hen-pecked husband who in his daydreams is a fabulous hero. Thurber's fables blend delightful nonsense with much wisdom about humanity. A play, *The Male Animal* (1940), written with Elliott Nugent, is an effective plea for academic freedom as well as a gay comedy. While a keen satirical sense is shown in many essays, parodies and burlesques, a gentle humour pervades such fairy tales as *The 13 Clocks* (1950). *The Thurber Album* (1952) is an affectionate account of family and friends in the midwest, and *The Years With Ross* (1959) is a witty record of associates on the *New Yorker*. The best collection of the writings and drawings is *The Thurber Carnival* (1945). Thurber died in New York city on Nov. 2, 1961. (Wm. B.)

**THURET, GUSTAVE ADOLPHE** (1817-1875), French botanist, noted for his work on the reproduction of algae, was born at Paris on May 23, 1817. After receiving a law degree in 1838, he studied under algologist Joseph Decaisne. He traveled to Constantinople in 1840 as French attaché, and after returning to France, being a man of independent means, devoted himself entirely to science. Thuret's first paper (1840) detailed the discovery of flagella of spermatozooids in the green algae *Chara*. In 1844 Decaisne and Thuret announced the finding of spermatozooids in the brown algae *Fucus*. The first accounts of fertilization and hybridization in *Fucus* were given by Thuret (1854), and later (1867), jointly with Edouard Bornet, he determined the complicated life cycle of Florideae, a group of red algae. His *Etudes phycologiques*, a folio volume containing observations on and illustrations of marine algae, was published posthumously in 1878. Before 1857, Thuret spent much of his time studying algae on the

Atlantic coast of France. In 1857 he moved to Antibes on the Riviera, where he established an outstanding botanic garden. Thuret died at Nice on May 20, 1875.

**BIBLIOGRAPHY.**—Accounts of Thuret in *Ann. Sci. Nat., Bot.*, series vi, vol. ii, pp. 308–360, listing publications (1875); in *Jour. of Bot.*, vol. xiv, pp. 4–9 (1876); and in A. Davy de Virville, *Histoire de la botanique en France* (1954). (J. W. Tr.)

**THURGAU** (THURGOVIE), a canton of northeast Switzerland (area 389 sq.mi. [1,007 sq.km.]), bordered by the Lake of Constance and, for a short distance, by the Rhine below the lake. It is connected with Schaffhausen and Zürich to the west and Sankt Gallen (St. Gall) to the south. Thurgau is divided into three hill masses: one stretching along the lake; another, inland, bounded on the north by the wide curve of the Thur River and on the south by its affluent the Murg; and the third at the southern extremity of the canton, merging into the pre-alpine zone of Mt. Hörnli.

In prehistoric times Thurgau's inhabitants included lake dwellers; later, for several hundred years up to A.D. 450, it was part of the Roman province of Raetia. An important Roman settlement was Arbor Felix (Arbon). It then passed into barbarian possession. From the 8th century it appeared as a political unit, extending as far west as the Reuss River and as far south as the foot of the Alps. In the later Middle Ages the county of Thurgau, already reduced in size, belonged to the counts of Kyburg, who became extinct in 1264, the county passing from the last count, Hartmann, to his nephew Rudolf I of Habsburg (German king from 1273). In 1460 it was seized by the confederated Swiss states and thenceforth ruled as a subject district. In 1798 it became a canton of the Helvetic Republic and in 1803 a full member of the Swiss Confederation. Its very advanced cantonal constitution dates from 1869.

The population (1960) was 166,420, mostly German-speaking, though small minorities spoke Italian and French; about two-thirds were Protestant and about one-third Roman Catholic. The capital is Frauenfeld (*q.v.*; pop. 14,702) on the Murg River; other centres are Kreuzlingen (12,597), Arbon (11,608), and Romanshorn (7,755).

Thurgau is a prosperous agricultural area famed for its apples and pears and for cider making. Vines are grown in the area bordered by the lake and in the Thur Valley. Industries include the manufacture of textiles, shoes, and motor vehicles; food preserving, printing, and handicrafts. The canton is traversed by the railway from Winterthur (Zürich) to Romanshorn, with branches to Constance, the Toggenburg Valley, and Sankt Gallen; another important line extends from Rorschach (Sankt Gallen) along the lake shore via Constance to Schaffhausen. Main roads follow these lines and there is a dense network of secondary roads.

(Br. M.)

**THURII** (THURIA, THURIUM), an ancient Greek city in Italy on the Gulf of Tarentum. It originated from an attempt by exiles from Sybaris (*q.v.*) and their descendants to resettle the site with Athenian assistance, after their first attempt (452 B.C.) had failed because of attack from Crotona. The original Sybarites were soon expelled (they founded a fourth Sybaris well away to the south). It was probably after this expulsion that the Athenians Lampon and Xenocritus led out a new body of colonists from all Greece (444/443). The city, renamed after a nearby spring, Thuria, was laid out on a rectangular plan by the architect Hippodamus of Miletus; the laws were said to be the work of Protagoras (*q.v.*).

Thurii flourished, but a severe defeat by the Lucanians (390/389) was the beginning of persistent danger, obliging the Thuriians to appeal to Rome for help and accept a Roman garrison in 282. In the Second Punic War the Thuriians joined Hannibal, who later removed them to Crotona (204). In 193 a Latin colony was founded at Thurii, known for a time as Copia, but afterward as Thurii.

Geophysical prospecting from 1960 onward, followed up by trial drilling and some excavation, located Roman and Greek remains just north of the Crati River about 1½ mi. inland; these have been tentatively identified with Copia and Thurii (previously thought to lie farther inland).

**THURINGIA** (THÜRINGEN), a historic region of Germany, extending eastward from the Werra River (a headstream of the Weser) into the country beyond the Saale as far as the Pleisse and northward from the mountains of the Thüringer Wald (Thuringian Forest) and the Frankenwald to the foothills of the Harz Mountains. Eisenach, Gotha, Erfurt, Weimar, Apolda, Jena, Gera, and Altenburg are towns on the west-east axis; Meiningen and Suhl stand in the southwest, Sondershausen and Nordhausen in the north.

**History.**—The Thuringians, a Germanic tribe first recorded in the second half of the 4th century A.D., were subjected by Attila the Hun in the second quarter of the 5th; but by A.D. 500 they had freed themselves and had established a great kingdom extending from the Harz Mountains to the Danube. In 531, however, their king Irminfrid (Irmfried or Herminfrid) was defeated in battle at Burgscheidungen on the Unstrut River by the Frankish kings Theuderic I and Clotaire I and put to death. Reduced territorially to the area between the Harz Mountains and the Thuringian Forest, the former kingdom was then governed by Frankish dukes, who acquired a growing degree of independence. To reassert the Frankish king's authority, Charles Martel (*q.v.*) abolished the office of duke and divided the province among Frankish counts, while the conversion of the Thuringians to Christianity was undertaken by St. Boniface (*q.v.*) in the early 720s. In 804 Charlemagne (*q.v.*) founded the Thuringian Mark (march or frontier zone) under ducal authority in order to protect the line of the Saale against the Slavs. But after Duke Thakulf (849–873) the defense of the Mark weakened; and after the death of Duke Burkhard in 908, Thuringia was seized by the Saxon duke Otto (*see SAXONY*). Otto's son and successor (from 912) was elected German king, as Henry I, in 919. He crushed a Magyar invasion of Thuringia at Riade in 933 and consolidated his defenses by forts (*Burgwarde*).

**The Ludowings.**—The direct line of German kings of the Saxon dynasty died out in 1024. Their territorial influence in Thuringia was replaced, from c. 1039, by that of Louis the Bearded (d. 1055 or 1080?), a member of the Ludowing family. His grandson was in 1130 appointed landgrave of Thuringia, as Louis I, by the German king Lothair III. Louis II (d. 1172), landgrave from 1140, married Judith (Jutta), stepsister of the future emperor Frederick I, in 1150; and later he supported Frederick in his conflict with Henry the Lion, duke of Saxony. Louis III (d. 1190), landgrave from 1172, was in 1179 appointed count palatine of Saxony as a reward for his fidelity to Frederick. On the other hand his brother and successor, Hermann I (d. 1217), sold his support to both parties during the war between the rival German kings Philip of Swabia and Otto IV. Hermann's son Louis IV (d. 1227) was the husband of St. Elizabeth of Hungary. Louis IV's son and heir, the young Hermann II, was kept in tutelage by his uncle Henry Raspe till his death in 1241, whereupon Henry Raspe became landgrave. Henry Raspe was elected German king in opposition to Conrad IV in 1246 but died in 1247 (*see HENRY, German kings*).

**The First Wettins.**—There followed a long dispute over the Ludowing succession. The two principal claimants were: Henry III the Illustrious, margrave of Meissen, of the House of Wettin (*q.v.*), son of the landgrave Hermann I's daughter Jutta; and Henry the Child, of the House of Brabant, son of Hermann II's sister Sophia. After war lasting from 1256 to 1263, Henry the Illustrious obtained the landgraviate of Thuringia in 1264, while Henry the Child obtained Hesse (*q.v.*). In 1265 Henry the Illustrious granted Thuringia to his son Albert, who sold it in 1293 to the German king Adolf of Nassau for 12,000 marks; but Albert's sons, Frederick the Dauntless (d. 1323) and Dietzmann (d. 1307), opposed this bargain, and Frederick was invested with Thuringia by the future emperor Henry VII in 1310. Frederick II (d. 1349), Frederick III (d. 1381), Balthasar (d. 1406), and Frederick IV extended their Thuringian possessions; but whereas the former two were margraves of Meissen as well as landgraves of Thuringia, the latter two (brother and nephew of Frederick III) were not margraves of Meissen, which passed to Frederick III's son, later elector of Saxony as Frederick I (from 1423). Frederick IV

of Thuringia, however, died childless in 1440, and his inheritance then reverted to Electoral Saxony.

**Thuringia Divided.**—The elector Frederick II of Saxony had to grant the landgraviate to his brother William in 1445. After William's death (1482) Ernest and Albert of Saxony in 1485 made a new partition of the Wettin inheritance: most of Thuringia went to Ernest, though Albert received a long strip of land in the north. For details of this partition and for the important modifications of it in the 16th century, see SAXONY.

The Ernestine Wettins remained in possession of the major part of Thuringia: for their multiple subdivisions of it, see SAXON DUCHIES, ERNESTINE. There were still, however, a number of smaller Thuringian territories independent of the Wettins: when the succession to the countship of Henneberg, in the southwest, fell open in 1583, the Wettins obtained the greater part of it, but had to let Schmalkalden go to Hesse-Kassel; the bishopric of Erfurt (*q.v.*), long the subject of competition between the Wettins and the archbishopric of Mainz, finally passed to Prussia in 1803; and both Reuss and Schwarzburg (*qq.v.*) survived all attempts at absorption by the Wettins.

Prussia obtained Albertine Thuringia from Saxony at the Congress of Vienna (1814–15) and Hessian Thuringia after the Seven Weeks' War (1866). At the German Revolution of 1918 the four Ernestine dukes, the two Reuss princes, and the Schwarzburg prince abdicated, and their territories became free states. In 1920 these territories (except Coburg, which opted for union with Bavaria) were merged in a new Thuringia, a *Land* of republican Germany, with Weimar as its capital. The frontiers remained anomalous: Erfurt was still attached to the Prussian province of Saxony; there were enclaves belonging to Prussian Saxony or to Prussian Hesse-Nassau surrounded by Thuringian territory; and conversely parts of Thuringia were enclaved within Prussian Saxony.

After World War II all Thuringia fell to the Soviet-occupied zone of Germany. Thanks to the destruction of Prussia, an enlarged *Land* Thuringia was constituted within the German Democratic Republic, with rationalized frontiers, including the southwest of the former province of Saxony and all the former enclaves; the capital was Erfurt. In 1952, however, when the East German *Länder* were dissolved, Thuringia was divided between the *Bezirke* (districts) of Erfurt, Suhl, Gera, and Leipzig.

See F. Schneider and A. Tille, *Einführung in die thüringische Geschichte* (1931).

**THURLES** (DURLAS ÉILE), a town of County Tipperary, Republic of Ireland, lies on both banks of the Suir River, 40 mi. (64 km.) E of Limerick by road. Pop. (1961) 6,421. It is the seat of the Roman Catholic archbishopric of Cashel and Emly. The town is the marketing and distributing centre for a large agricultural area and has a beet-sugar factory. It is also a well-known sporting centre, with horse racing, hunting, golf, hurling, football, and trout fishing. The Gaelic Athletic Association was founded there in 1854.

Originally called Durlas O'Fogarty, Thurles was the scene in 1174 of the defeat of Strongbow (the 2nd earl of Pembroke) by Roderick O'Connor and Donal O'Brien. The Knights Templars held a 13th-century castle there and founded a preceptory. There was a Carmelite priory from 1300 until it was suppressed in 1540 and granted to James Butler, earl of Ormonde. The cathedral (1857–75) was built in Romanesque style on the site of the old Carmelite priory. Bridge Castle and Black Castle, two rectangular keeps, are all that remain of the Butler family's castles. Thurles' chief glory is the Abbey of the Holy Cross (about 3½ mi. SW), founded by Donal O'Brien for Benedictines or monks of the Columban Order and transferred to the Cistercians about 1182. A relic of the True Cross (now in the Ursuline convent at Blackrock, Cork) was enshrined in the abbey from the early 12th century until its suppression in 1536. The abbey was much restored and its ruins are well preserved.

**THURLOE, JOHN** (1616–1668), English politician, head of the government intelligence service during the Commonwealth, was the son of Thomas Thurloe, rector of Abbess Roding in Essex. After studying law he entered the service of the lawyer Oliver

St. John, through whose influence he was appointed a secretary to the parliamentary commissioners at Uxbridge in 1645. On March 29, 1652, he was appointed secretary to Oliver Cromwell's council of state. In Cromwell's administration he controlled the intelligence department at home and abroad; he perfected a system of collecting information and of discovering the plans of Cromwell's enemies that averted any danger of the government's being overthrown. He represented Ely, in Cambridgeshire, in the Parliaments of 1654 and 1656, and in July 1657 was appointed a member of Cromwell's second council. Thurloe supported the succession of Richard Cromwell (September 1658) and was member for Cambridge University in the Parliament of January 1659 where he was the government's chief spokesman. Deprived of his offices on the recall of the Rump Parliament (May 1659), he was reappointed secretary of state on Feb. 27, 1660. He opposed the restoration of Charles II and was arrested for high treason on May 15, 1660. Released on June 29, subject to attending the secretaries of state "for the service of the state whenever they should require," he subsequently wrote several papers on foreign policy for the earl of Clarendon. Thurloe died in London on Feb. 21, 1668. A collection of his state papers, one of the chief sources of information for the period, was published in seven volumes in 1742.

**THURLOW, EDWARD THURLOW, 1ST BARON** (1731–1806), was twice lord chancellor of England (1778–83; 1783–92). Though his tenure was a long one, he is remembered more for his oratory, his caustic wit, and his bad temper than for his legal acumen. Thurlow was born at Bracon Ash, Norfolk, on Dec. 9, 1731, the first son of an Anglican clergyman of modest economic circumstances and no connections. After going down from Cambridge without a degree because of indolence and insubordination, traits he retained throughout his life, he was admitted to the Inner Temple in 1752 and called to the bar in 1754. His signal triumph over Fletcher Norton, in a case tried before Lord Mansfield in 1758, marked the turning point of his career. He precociously became king's counsel in 1762. An impromptu argument in Nando's coffeehouse—whose barmaid was to become mother of his three daughters though not his wife—caused him to be retained in his greatest success as counsel in the case involving the heirship to the great Douglas estates. In 1765 he entered Commons as a member for Tamworth. There, his strong opposition to the notorious John Wilkes (*q.v.*) was followed by his appointment as solicitor general in 1770. His speeches against jury trial in libel cases and his prosecution of the publishers and printers of the "Junius" (*q.v.*) letters brought him the attorney general's post in 1771. His oratorical capacities, well displayed in venomous attacks on Lord Clive and the American colonies and his defense of the slave trade, caused his party to elevate him to the peerage and the lord chancellorship. He ruled in the House of Lords with an iron hand. A Tory by declaration, his sole guiding principle was expediency, which generally led him to support the will of King George III, a course that permitted him to retain his high post in such disparate ministries as those of North, Rockingham, Shelburne, and Pitt. He died on Sept. 12, 1806, at Brighton.

Thurlow had few friends and many enemies, the latter including the greatest politicians of his time: the younger Pitt, Charles James Fox, and Edmund Burke. In law, his greatest claim on posterity derives from his sponsorship of John Scott, later Lord Eldon. Perhaps equally important were his kindnesses to the poet George Crabbe and to Samuel Johnson. His portraits, painted by Reynolds, Romney, and Lawrence, among others, reveal a swarthy complexion, harsh but regular features, sparkling dark eyes, and a severe demeanor. But not even these masters could portray the voice which was his outstanding feature and the cornerstone of his career.

**BIBLIOGRAPHY.**—There is a bibliography in the only full-length biography, Robert Gore-Browne, *Chancellor Thurlow* (1953); see also Campbell, *Lives of the Lord Chancellors*, vol. vii (1846); H. P. Brugham, *Statesmen in the Time of George III*, 6 vol. (1845).

(P. B. K.)

**THURROCK**, an urban district (1936) in the Thurrock parliamentary division of Essex, Eng., lying along the north bank of the Thames. This area, mainly agricultural, was largely reclaimed

from the marshes by Dutch workers, who also used chalk from the Purfleet quarries in the embankment of the Thames in the 17th century. Area 63.4 sq.mi. (1,642 sq.km.). Pop. (1961) 114,263.

Grays, 23 mi. (37 km.) E of Charing Cross, London, by road, is the administrative centre. Originally a fishing village, it became a large river port for the hay and corn market and was further enlarged when the Tilbury docks (2½ mi. SE) were built. In 1906 an artificial beach of fine sand was made there.

Tilbury (*q.v.*) docks were constructed in 1884–86 on land that had been, until 1852, uninhabited marsh. They were built by the East and West India Dock Company and are now owned by the Port of London Authority. The original blockhouse at Tilbury, which was built by Henry VIII, was rebuilt in the 17th century. It was taken over by the ministry of works in 1949 and opened to the public in 1958. The fort has a gateway by Inigo Jones. It was at West Tilbury that Elizabeth I made her famous speech to her troops in 1588 at the time of the Spanish Armada. East Tilbury is built on the site of a 7th-century monastery, and the church, like many others in the district, dates from the 13th century.

At Mucking (Anglo-Saxon, "much pasture") is St. Clere's Hall (formerly New Jenkins), dating from Elizabethan times; Ford Place, at Stifford, rebuilt in 1655, has beautiful plaster ceilings. In 1381 Jack Straw, the revolutionary priest of Fobbing, led the peasants in revolt against the poll tax, and in the marshes nearby the last great prizefight with bare knuckles is said to have taken place. Orsett was once the seat of the bishops of London. Aveley is a residential area on rising ground and near the village is the mansion of Belhus in what is now a public park.

Thurrock's industries stretch along the 20 mi. of Thames-side. There are a paperboard mill, soap and margarine works at Purfleet; several cement works; timber yards at Grays; a shipbreaking yard; Tilbury docks with a passenger landing stage; a large shoe factory with its own technical college (1948) at East Tilbury; and, at the eastern end of the district, the Shell Haven oil refinery at Thames Haven and a refinery at Coryton for storing, blending, and refining oil. The West Thurrock industrial estate along the river bank covers over 4 sq.mi. and special facilities and concessions are granted to occupiers.

**THURSO**, the most northerly town on the mainland of Scotland. A small burgh and seaport of Caithness, it lies at the mouth of the Thurso River on Thurso Bay, 20 mi. WSW of John o'Groats by road. Pop. (1961) 8,037. In Sir John Square there is a statue of Sir John Sinclair (1754–1835), who did much for the improvement of Scottish agriculture. The town hall contains a public library and a museum with the collections of the "Thurso baker" and self-taught geologist and botanist, Robert Dick (1811–66). There is an atomic power station (begun 1954) at Dounreay, 8 mi. W of Thurso, and nuclear submarine training and research establishments are in the vicinity. The population increase (4,789) of Thurso between 1951 and 1961 is mainly accounted for by this. Thurso is one of only two small burghs that is a planning authority, and in the early 1960s it was being replanned.

Thurso was the centre of Norse power on the mainland when it was at its height in the early 11th century and afterward till the defeat of the Norwegians at the Battle of Largs (1263). In 1330 the weights and measures of Thurso were adopted for all Scotland. It was made a free burgh of barony by Charles I in 1633. To the east is Thurso Castle, and near it is Harold's Tower, built over the grave of Earl Harold, once owner of half of Caithness and half of the Orkneys and Shetlands, who fell in battle with Earl Harold the Wicked at the end of the 12th century. About ¼ mi. W stand the ruins of the palace of the bishop of Caithness, destroyed by fire in 1222.

**THURSTAN** (d. 1140), Norman archbishop of York, a native of Bayeux, rose rapidly in the service of William II and of Henry I, by whom he was appointed archbishop (1114). But Ralph, archbishop of Canterbury, refused to consecrate him without a profession of obedience. This Thurstan would not give, and with papal support he defied king and archbishop at the Salisbury Council (1116). After three years of deadlock he was consecrated by Pope Calixtus II at Reims (October 1119). He was reconciled with Henry I in 1120, partly through the help of Henry's sister

Adela of Blois. Thurstan's return to York (1121) was a triumph and for the next 19 years he proved himself an outstandingly energetic and inspiring archbishop, developing the parochial system, extending generous patronage toward the religious orders, especially the Austin canons and the Cistercians, and enlarging the endowments of the minster churches at York, Southwell, Beverley, and Ripon. He continued to be involved in disputes with Canterbury, and even more with the Scottish bishops, especially with John, bishop of Glasgow. Yet for the good of religion in 1127 he agreed to consecrate Robert, bishop of St. Andrews, without any profession of obedience. In 1138 he inspired the mainly Yorkshire army which defeated the Scots at the Battle of the Standard. In January 1140 he entered the Cluniac order at Pontefract, where he died on Feb. 6, 1140.

See D. Nicholl, *Thurstan, Archbishop of York* (1964).

(G. W. S. B.)

**THURSTONE, LOUIS LEON** (1887–1955), U.S. psychologist, contributed the method of multiple-factor analysis in the application of statistical methods to psychological problems. He was born in Chicago, Ill., May 29, 1887. After taking an engineering degree from Cornell University, Ithaca, N.Y., he served as assistant to Thomas Edison and taught engineering at the University of Minnesota, Minneapolis. An interest in the mathematical relations between amount of practice and improvement in performance led him to the University of Chicago, where he received a Ph.D. in psychology and where he remained for most of his professional life thereafter. Thurstone died in Chapel Hill, N.C., Sept. 29, 1955.

Most notable among Thurstone's accomplishments were improved methods of measuring intelligence and his development of multiple-factor analysis. The latter is widely used in research on the nature of human ability and for the practical purpose of constructing tests to measure different types of ability. His literary output was comparatively small, including a score or two of research papers and a few books and monographs, but these were so influential that he was one of the United States' most frequently quoted psychologists. Thurstone's major books are *Vectors of the Mind* (1935) and *Multiple-Factor Analysis* (1947).

See also INTELLIGENCE: *Relation of Intelligence to More Specialized Abilities*.

See D. A. Wood, *Louis Leon Thurstone* (1962).

(DL. W.)

**THUTMOSE** (THOTHMES; Greek TUTHMOSIS), the name of four pharaohs of ancient Egypt during the first half of the 18th dynasty (16th and 15th centuries B.C.). The name means "Born of (the god) Thoth."

**THUTMOSE I** (Aakheperkare; 1525–1512 B.C.) was the son of a commoner and appears to have acquired the throne through marriage with a royal princess, Ahmose. Early in his vigorous reign he led his armies northward to the Euphrates in a campaign of unprecedented success and set up a monument on the riverbank at the point of his farthest advance. On his return march he hunted elephant in the Syrian plain. In the south, he pushed the frontier of Egypt upstream to the Dongola reach of the Nile and reopened the ancient trading post at Kerma near the Third Cataract. His architect Ineni was in charge of the erection of a courtyard and a columned hall with a cedar roof in the temple at Karnak (see THEBES). In front of the latter he erected two granite obelisks. Ineni also supervised the construction of the king's tomb, the first to be hewn in the Valley of the Tombs of the Kings "in secret," as he himself says, "none seeing and none hearing."

**THUTMOSE II** (Aakheperenre; 1512–1504), a son of Thutmose I by a minor queen, married his half sister Hatshepsut (*q.v.*). Before his untimely death he made some show of arms against the Palestinian Bedouin and crushed a rebellion in Nubia with severity.

**THUTMOSE III** (Menkheperre; 1504–1450), who was to prove the greatest of his name, the son of Thutmose II by a concubine, legitimized his succession by marrying the daughter of his aunt and regent Hatshepsut. Succeeding as a minor, he had to wait 22 years before, at Hatshepsut's death, he was able to assume sole power and embark on the career of conquest for which, as a trained soldier, he was fitted. In 17 campaigns this remarkable man re-established, on a firmer footing than ever before, Egyptian sov-

reignty in southwestern Asia. The first campaign is recorded in some detail on the walls of his temple at Karnak: the march to Gaza, and then to Yahmai south of the Carmel Range; and the council of war and the king's bold decision to surprise the allies of the enemy, led by the king of Kadesh, who were encamped at Megiddo northeast of Carmel and about 18 mi. (29 km.) SSE of the modern city of Haifa. The approach by the route least expected, a narrow defile over the mountain, was successful, the enemy army was defeated, and Megiddo was taken after a siege of eight months. In subsequent campaigns, which are less fully described, ports on the Phoenician coast were converted into Egyptian supply bases, and Kadesh and other cities in the Bika (Bekaa) Valley were taken. The time was then ripe for his most audacious move, an attack against the kingdom of Mitanni, grown stronger since the day when Thutmose I had taken its army by surprise. The Egyptians planned the campaign well; vessels were transported across Syria on ox-carts for the Euphrates crossing. Triumphantly Thutmose III set up his stela beside that of his grandfather. It was his farthest point of advance. On the homeward journey he too hunted elephant, and on his return he celebrated a great victory at Thebes. In later campaigns he was content to consolidate what he had won and to lay the foundations of an imperial organization of his Asian possessions. Local princes, often educated in Egypt, were henceforward set to govern their own territories as vassals of pharaoh and were bound by solemn oath to keep the peace, send annual tribute to Egypt, and obey the Egyptian resident governor, the "overseer of foreign lands."

To the south, Thutmose extended the boundary of Egyptian dominion over Cush to Karoy, near Napata, a little below the Fourth Cataract, thoroughly subduing the turbulent Nubians and developing the gold mines which, from his reign on, became the basis of Egypt's wealth in foreign trade. For the last 12 years of his reign he was content to enjoy the fruits of his victories. The tribute of Syria and Palestine and of the Sudan poured into his treasury, and the tombs of his high officials are decorated with scenes depicting the reception of foreign envoys from places as far away as the Aegean and the Greek mainland, bringing their rich gifts to lay at pharaoh's feet. The temple of Amon at Karnak in particular was enriched by many new buildings and a number of obelisks. During his reign, art and craftsmanship received new impetus from his patronage. He was not only an able soldier and administrator but a considerable athlete, whose prowess with the bow was demonstrated in public display.

THUTMOSE IV (Menkheprure; 1425–1417) was the son of Amenhotep II. After a brief campaign against the Mitannians he made peace with them and married the daughter of Artatama, the king of Mitanni. See also *EGYPT: History*.

(M. S. Dr.)

**THYMELAEACEAE**, the mezereon family of dicotyledonous plants, with about 40 genera and in excess of 700 species recognized. They are mostly shrubs or trees, rarely herbaceous, and representatives occur in most parts of the world, even in Arctic regions. Large genera are *Gnidia*, chiefly African, *Wikstroemia*, chiefly Indo-Malaysian, and *Pimelea*, chiefly Australian. The bast fibres of *Edgeworthia* are very strong, and are extensively utilized in various parts of the world, and especially in Japan, for manufacturing thin, tough writing paper called *mitsumata*. Eaglewood or agalloch, prized because of its pleasant odour, is the product of representatives of the genus *Aquilaria*. Among the few genera cultivated for ornament in warmer regions are the laurelike shrub *Daphne* (q.v.), *Dirca* (leatherwood), and *Pimelea* (rice flower).

(E. D. Ml.)

**THYMUS.** The thymus is a soft, flattened organ lying behind the breastbone. Its function is not well understood. It consists of two lobes of unequal size, which partly cover the trachea, the large vessels in the chest, and the serous covering of the heart, the pericardium. As a food, the animal thymus is called the sweetbread or, more specifically, neck sweetbread, to differentiate it from the pancreas, the stomach sweetbread. During life, the

thymus changes markedly in absolute and relative size. It is proportionately largest at birth, averaging about 12 g. ( $\frac{1}{2}$  oz.), 0.42% of the total body weight. At the age of puberty the thymus reaches its absolute maximum size, about 37 g. ( $1\frac{1}{2}$  oz.). After puberty the organ gradually decreases in size (involution) until, between age 60 and 70, the average weight is around 6 g. ( $\frac{1}{4}$  oz.). Large individual deviations from these averages may occur. In addition to physiologic involution, a much more rapid so-called accidental involution may take place as a result of infection, poisoning, or starvation.

**Functions.**—Although the thymus has the microscopic structure of a lymphatic organ and as such participates in the production of lymphocytes, many studies have seemed to show that the thymus is an endocrine organ. The thymus reaches its maximum size during puberty and then involutes; that suggested to some investigators that the organ plays an active role in processes of growth and sexual maturation. Experiments with injections of thymus extracts into rats led to similar assumptions. However, the growth of the thymus as well as its involution is essentially no different from the same process in other lymphatic organs, and the experiments with thymus extracts were not substantiated. Injections with pituitary growth hormone result in an increase in the size of the thymus, while removal of the pituitary as well as administration of steroid hormones, including the sex hormones, tends to decrease its size. It is possible that these hormones are instrumental in the normal growth and involution of the thymus. It has been suggested that accidental involution may be caused by a high level of secretion of adrenal cortical steroid hormone.

**Structure.**—The thymus is encased in a thin capsule of connective tissue. This connective tissue penetrates the interior of the organ in the form of walls that branch and fuse, thus dividing the thymus into a multitude of connecting lobules .05 to 2 mm. ( $\frac{1}{16}$  to  $\frac{1}{8}$  in.) in diameter. The thymus tissue itself contains two types of cells, reticular cells and lymphocytes. The reticular cells, which are larger than the lymphocytes, are characterized by a large pale nucleus; they form a three-dimensional network, in the meshes of which the lymphocytes are found. In the peripheral areas of the lobules, the so-called cortex, the lymphocytes are more densely packed and the reticular cells relatively more sparse. The central zone of the lobule, the medulla, contains fewer lymphocytes and more reticular cells than the cortex. The reticular cells of the thymus differ from the reticular cells of other lymphatic tissues in that they are derived embryologically from epithelial tissue and not from the mesenchyme (the embryologic connective tissue). The lymphocytes of the thymus are not only morphologically identical with the lymphocytes of other lymphatic tissues; they also exhibit the same physiologic behaviour and the same reactions to noxious stimuli. In the medulla of the thymus are the so-called Hassall's bodies. These structures are composed of concentrically arranged cells, which are degenerated at the centres of the bodies where also processes of cornification can frequently be seen. The function of Hassall's bodies, if any, is unknown.

The involution of the thymus consists microscopically of a decrease in the amount of thymus tissue, which is replaced by fat tissue originating in the interlobular connective tissue. This process affects first the cortex but gradually extends also to the medulla, which decreases in quantity. Finally the thymus becomes a mass of fatty tissue containing centrally a remnant of the medulla with varying numbers of Hassall's bodies.

**Embryology.**—The thymus arises from the third branchial pouch in the form of two epithelial cell masses, which at first are tubular but subsequently become solid. Lymphocytes wander in from the surrounding mesenchyme, thus separating the densely packed epithelial cells and converting the solid cell mass into a reticulum. The lymphocytes of the thymus are not derived from the epithelial cells.

(P. P. H. De B.)

**Diseases.**—The function of the thymus and its relationship to clinical disease are not well understood. Experimental removal of the thymus in animals has given no conclusive results. Myasthenia gravis, a paralytic disease, is often associated with a tumour of the thymus; and in many cases of hyperthyroidism, a disease asso-

ciated with thymic enlargement, muscular weakness is a prominent feature. In a number of cases a thymic tumour has been associated with depressed red blood cell formation and anemia which is at times relieved by surgical removal of the tumour. Certain relationships have been found between the thymus and the transmissibility of leukemia in experimental animals. A great deal has been written about the relationship of thymus enlargement to sudden death in infants, particularly during anesthesia. Evidence indicates, however, that the thymus—originally described as enlarged and as associated with the syndrome known as lymphatic constitution or status thymicolymphaticus—is normally developed in such cases, and that the symptoms in such patients are usually caused by infections of the respiratory tract and other local or general conditions. All tumours originating in the thymic area should be regarded as potentially malignant.

See also LYMPH AND LYMPHATIC SYSTEM. (A. M. Hy.)

**THYROID GLAND** is an endocrine gland in the throat below the larynx (voice box). It secretes a hormone that has a key role in metabolism and growth. The gland consists of two oblong lobes lying on either side of the windpipe and connected by a narrow band of tissue called the isthmus. The lobes of the gland as well as the isthmus consist of numerous tiny hollow sacks called follicles, more or less rounded in shape and varying from 0.05 to 0.5 mm. ( $\frac{1}{40}$  to  $\frac{1}{16}$  in.) in diameter. The shell of each follicle is built of cells closely packed together and is wrapped in a thin membrane (see figure). The membrane is covered with a dense mesh of blood capillaries, which ensure a steady and abundant supply of fresh plasma through the membrane to the cells; in fact, the thyroid gland is one of the most extensively vascularized organs. Besides blood vessels, there are also lymph vessels and nerves around the follicle. The space inside the follicle is filled with a viscous fluid called colloid.

Every follicle of the thyroid gland makes thyroid hormone, stores it and secretes it into the blood stream. This hormone consists of two chemically closely related substances, L-thyroxine (or L-tetraiodothyronine) and L-triiodothyronine. Under normal conditions, most of the hormone is made up of thyroxine. The four and three atoms of iodine present in these two molecules account, respectively, for 65% and 58% of the hormone weight. It is possible to administer radioactive iodine and trace its progress in the thyroid, to observe how the gland uses it to make up the hormone. The iodide diffusing from the blood capillaries into the cells is retained by and concentrated in the cells. Then the iodide is taken up into organic compounds to form thyroxyl and triiodothyronyl radicals, which are thyroxine and triiodothyronine attached to a large protein called thyroglobulin. This phenomenon occurs

at the edge of the cells next to the colloid. The new thyroglobulin becomes mixed with the thyroglobulin present in the colloid and stays there, thus providing a hormone store. Release of the hormones occurs when an enzyme, presumably secreted by the thyroid cells into the colloid, breaks down thyroglobulin to its amino acid components. The thyroxine and triiodothyronine molecules thus freed are small enough to cross the cell wall and to enter the blood vessels around the follicle; they become distributed over the entire body.

In blood the thyroid hormone binds loosely to plasma proteins, mainly to  $\alpha$ -globulin. To measure the level of thyroid hormone in the blood, the hormone is separated from inorganic iodine (iodide) by isolating plasma proteins, and the iodine content of these proteins is determined. The amount of so-called protein-bound iodine indicates whether or not the thyroid hormone level is normal. Too low or too high

levels cause widespread functional disturbances, since the hormone controls the oxidation rate of foodstuffs inside the cells over the entire body (see THYROID GLAND, DISEASES OF).

The amount of thyroid hormone secreted by the thyroid gland is controlled by another endocrine gland, the pituitary. When the level of thyroid hormone in blood diminishes, due to its utilization in the tissues, the pituitary gland releases a hormone which stimulates the thyroid. This thyroid-stimulating, or thyrotrophic, hormone first induces the release of the thyroid hormone stored in the colloid by accelerating the breakdown of thyroglobulin. The amount of colloid in the follicle diminishes and may even nearly disappear under prolonged stimulation. The thyroid cells increase in size by protruding inside the follicle, and thus increase their capacity to produce the hormone. Under normal conditions, the appropriate level of thyroid hormone in the body is readily re-established; this higher level induces the pituitary to stop releasing thyrotrophic hormone; the thyroid stimulation ceases, the stores of thyroglobulin are repleted and the cells regress to their original size. Thus the level of thyroid hormone in the body is kept within a constant range by a mechanism in which the effects of thyroid hormone and of thyrotrophic hormone work in closed cycle (feedback mechanism), each hormone controlling the secretion of the other.

(H. G. I.)

**THYROID GLAND, DISEASES OF.** In general it may be said that the thyroid gland is subject to the same types of disease processes that affect the other glands of internal secretion. The gland may secrete an excessive quantity of thyroid hormones (hyperthyroidism) or the secretions may be deficient (hypothyroidism). The gland may be enlarged (in which case it is called a goitre) or atrophic. (For a discussion of the anatomy and physiology of the thyroid gland see THYROID GLAND; ENDOCRINOLOGY: *Thyroid Gland*; HORMONES: *Thyroxine*.)

**Goitre.**—Most goitres are benign; a small minority of goitres are cancerous. Inflammatory diseases of the thyroid gland are also associated with enlargement.

The normal thyroid gland weighs 20 to 30 g. (about  $\frac{1}{2}$  oz.); goitres may weigh as much as 1 kg. (more than 2 lb.). The goitrous glands are usually confined to the neck but occasionally they may extend into the upper chest or more rarely they may be entirely within the chest.

Endemic goitres occur in a relatively large proportion of the population in those areas of the world in which the iodine content of the drinking water and food is exceedingly low. Switzerland and the Great Lakes region in the United States are notable in this regard. Iodine is an integral part of the amino acid thyroxine and the closely related compounds that comprise the thyroid hormones. When the iodine is not supplied in sufficient quantity the gland may hypertrophy, presumably in an effort to produce an optimum amount of hormone. At first there may be a diffuse enlargement of the gland but eventually nodular growths evolve. When the iodine deprivation has been extreme for years, hypothyroidism develops and the children of such individuals may be cretins (see CRETINISM). Supplementing the usual iodine intake by the addition of iodide to table salt has been shown to prevent many goitres in endemic areas.

Nodular goitres are those which develop initially from nodules, or nonencapsulated swellings, within the gland. (To simplify the discussion, the term nodular goitre here includes the far less common adenomatous type, in which the initial site of enlargement is an adenoma, or encapsulated swelling.) These goitres occur sporadically in areas where goitres are nonendemic, as well as in endemic areas where iodine replacement is practised. Nodular goitres usually are not accompanied by hyperthyroidism or hypothyroidism. The specific cause of any particular nodular goitre may not be ascertainable. However, varying combinations of several different factors are known to account for many of these abnormal growths.

In some individuals thyroid enlargement is the result of a genetically determined defect in the biosynthesis of thyroid hormone.

THYROID FOLLICLE

From periphery to centre are shown blood vessels (BV), membrane (M) and cells (CE) which make up the shell of the follicle. Appearing on the section plane are the nuclei (N) and the colloid (CO) which fills the space inside the follicle

rated from inorganic iodine (iodide) by isolating plasma proteins, and the iodine content of these proteins is determined. The amount of so-called protein-bound iodine indicates whether or not the thyroid hormone level is normal. Too low or too high

In rare cases this results in a failure of the gland to secrete significant quantities of hormonally active substances and the unusual growth of the gland is accompanied by hypothyroidism. Probably more frequently these defects in the biosynthetic processes are partial, normal thyroid function being maintained by compensatory hypertrophy (goitre formation). Enlargement of the thyroid sometimes occurs as a normal accompaniment of pregnancy, and about 80% of nodular goitres are seen in women. This suggests that cyclic variations in ovarian and pituitary activity may alternately stimulate and inhibit the thyroid and thus play a role in the genesis of nodular enlargements. It is also possible that goitrogenic chemicals found in small quantities in foodstuff (e.g., cabbage) may be provocative in this regard. Some drugs, most notably thiocyanates and thiourea derivatives, also possess goitrogenic properties. Thiocyanates inhibit the iodide trapping mechanism in the gland; the thioureas actually block the synthesis of the hormone. In either case thyroid hypertrophy results, probably as a result of compensatory pituitary stimulation.

Nodular goitres should be removed surgically whenever they interfere with the functioning of neighbouring organs. Difficulty in breathing and swallowing, due to pressure on the windpipe and esophagus, are the most frequent indications. A relatively rapid growth of the tumour suggests the possibility of malignancy and thus provides an additional indication for surgical treatment. Endemic goitres may slowly diminish in size with iodide administration. Some sporadic goitres respond to treatment with replacement doses of thyroid extract.

**Cancer.**—Carcinomas of the thyroid appear to develop with unusual frequency in nodular goitres, especially those with only a single nodule or adenoma. Despite the considerable frequency of goitres, the incidence of death from carcinoma of the thyroid is among the least frequent causes of death from cancer. Nevertheless, the low morbidity and mortality that attend thyroidectomies have persuaded many physicians to advise the removal of all so-called solitary adenomas as a prophylactic measure. X-ray treatment of the head, neck and chest in children has been shown to be one of the causes of carcinoma of the thyroid in adolescence and young adulthood. Carcinoma of the thyroid rarely occurs in nodular goitres in persons 60 years old or older.

**Thyroiditis.**—Hashimoto's struma and Riedel's struma are chronic inflammatory disorders of the thyroid gland that may simulate other goitres. Both are quite rare. The end result of chronic thyroiditis of either type is frequently the complete destruction of active thyroid tissue and thus the production of the clinical signs and symptoms of hypothyroidism. There are no hints as to the cause of Riedel's struma. Hashimoto's struma is now thought to be an autoimmune disease since antibodies against thyroid tissue can usually be found circulating in the plasma of patients with this disorder. Subacute thyroiditis is more common than either of the chronic disturbances and can be readily distinguished because the enlarged gland is almost always exquisitely tender and painful. It is associated with fever and malaise and is probably due to a viral infection.

**Hyperthyroidism.**—Hyperthyroidism, also called thyrotoxicosis, may occur with diffuse or nodular goitre. It is characterized by signs of increased metabolism, nervousness, rapid heartbeat, weight loss usually with enhanced appetite, fatigue, heat sensitivity and excessive sweating. In Graves' disease the hyperthyroidism is accompanied by exophthalmos (protrusion of the eyes) and the thyroid gland is usually diffusely enlarged. Exophthalmos is rare when nodular goitres become overactive. The diagnosis of hyperthyroidism in patients with nodular goitre is especially difficult because of the usual insidious onset.

Hyperthyroidism can be treated in one of several ways. Subtotal thyroidectomy is the usual procedure of choice in younger patients. Such surgery must be preceded by medical control of the hyperthyroidism; this is carried out by combined treatment with one of the thiourea derivatives such as propylthiouracil (6-propyl-2-thiouracil) together with iodides (Lugol's solution).

In older patients surgery can be avoided by employing radioactive iodine ( $I^{131}$ ). This isotope of iodine is taken up by the thyroid cells just as is the nonradioactive  $I^{127}$  in the course of

hormonal biosynthesis and secretion. When present in sufficient dosage  $I^{131}$  results in the destruction of the cells. The dosage can be regulated so that sufficient undamaged tissue remains to maintain normal thyroid function in most cases. In occasional patients with Graves' disease protracted treatment with propylthiouracil or a related drug alone has been successful in inducing a lasting remission.

**Hypothyroidism.**—Hypothyroidism may result from destruction of the thyroid gland by inflammatory disease or  $I^{131}$ , the removal of all functioning thyroid tissue surgically, hypopituitarism or idiopathic atrophy of the gland. It is characterized by signs and symptoms of diminished body metabolism, lassitude, sensitivity to cold, dry skin, poor memory, deposits of mucinous fluids subcutaneously and elsewhere (myxedema; *q.v.*), the loss of scalp hair, etc.

Replacement therapy must usually be initiated slowly, especially in older patients. Treatment is ultimately remarkably effective regardless of whether desiccated thyroid extract or synthetic hormonally active substances like thyroxine or triiodothyronine are employed.

**Diagnostic Tests.**—Although the thyroid hormone is not the only secretion that affects the rate of general body metabolism, measurement of the basal metabolic rate (BMR) is particularly useful as a means of evaluating thyroid function. The BMR is elevated in hyperthyroidism and depressed in the deficiency state. The level of circulating thyroid hormone can be estimated with considerable precision by measuring the protein-bound iodine (PBI) in the plasma or serum. Functional activity of the thyroid gland can also be evaluated by measuring the rate of uptake of tracer doses of radioactive iodine. In hyperactive glands the turnover of iodine is accelerated. In hypothyroidism little or no radioactive iodine would be taken up by the gland. Serum cholesterol is elevated in hypothyroidism and tends to be somewhat lower than normal in hyperthyroidism; this characteristic is employed as the basis for a thyroid function test. The detection of high titres of antithyroid antibodies in serum may be used as a presumptive test for Hashimoto's struma.

**THYSANOPTERA**, the name of a small order of insects commonly known as thrips. See THIRIPS.

**THYSANURA**, an order of primitive wingless insects comprising the bristletails, silverfish (*q.v.*), and firebrats. See also APTERYGOTA.

**THYSDRUS** (modern EL DJEM or AL JAMM), an ancient Roman city 39 mi. (63 km.) S of Sousse (Susah) in Tunisia. Originally a native community influenced by Carthaginian civilization, it probably received veteran soldiers of Julius Caesar's as settlers in 45 B.C. and ultimately became a Roman *colonia*. The wealth of its territory is shown by its capacity to build a vast amphitheatre (163 × 133 yd. [149 × 122 m.]), probably in the 3rd century A.D., the largest Roman monument in Africa and second in impressiveness only to the Colosseum at Rome. (B. H. W.)

**THYSSEN, AUGUST** (1842–1926), German industrialist, "steel baron of the Ruhr territory," was born at Eschweiler, May 17, 1842. Thyssen's rolling mill, founded in 1867, became Thyssen and Co. in 1871 when he originated "vertical cartelization," unifying the financial, technological, and market controls of facilities for producing basic steel with operating properties in related industries, such as coal mining. Thyssen sought additional private gain by vertical cartelization and was pressed to accelerate it by Bismarck, who saw in the technical integration which accompanies cartelization, a means of speeding military production. In addition to his practical motives, Thyssen had a pronounced technological bent, being first among German steel men to introduce the blast furnace as well as the Thomas process for utilizing the rich bed of phosphoric ore in Alsace-Lorraine in conjunction with the abundant coking coal of the Ruhr Valley. Thyssen's great financial power, later augmented by collaboration with his son, Fritz Thyssen (1873–1951), was used after World War I for political manipulations detrimental to the Weimar Republic and beneficial to Adolf Hitler.

Thyssen died at Landsberg castle, near Kettwig, April 4, 1926. (G. W. Z.)

**TIARA**, the papal crown, the ensign of sovereign power. See **VESTMENTS, ECCLESIASTICAL**.

**TIBER** (ancient *Tiberis*, Italian *Tevere*), the longest river of the Italian peninsula, rises in the Etruscan Apennines, on the slopes of Monte Fumaiolo, 4,160 ft. (1,268 m.) above sea level and 12 mi. (19 km.) N of Pieve Santo Stefano. After a short and precipitous upper course through deep ravines, the Tiber enters the wide Val Tiberina near Sansepolcro, flows southeast past Umbertide and Perugia, turns west at Todi, and, after receiving the waters of the Paglia below Orvieto (draining the southern Val di Chiana), turns southeast again. It is then joined by the Nera near Orte, skirts the foothills of the Sabini (Sabine) Mountains, and turns southwest at Passo Corese. After passing through Rome, the river enters the Tyrrhenian Sea through a northern artificial mouth at Fiumicino, and a southern one at Ostia. In its lower course the Tiber is joined by the Aniene. Claudius and Trajan both built canals in the Tiber delta, as well as ports to handle the seaborne commerce of Rome for transshipment by river to the city. The total length of the river is 252 mi. (405 km.); its drainage basin is 6,719 sq.mi. (17,402 sq.km.). In its lower course the river winds its way through numerous meanders; only through and below Rome has its course been straightened to any extent. Depths vary from 7 to 20 ft. (2 to 6 m.) and navigation is only carried on as far as Rome. The sediment load is heavy; the mouth of the river has advanced about two miles since Roman times, and the sediment can be seen up to ten miles away on either side of the mouth.

Several popes were anxious to develop navigation on the lower Tiber and ports were built in Rome in 1692, 1703, and 1744. The golden age of river navigation was the late 18th century and the first half of the 19th, although as late as 1910 numerous river boats could be seen in Rome itself. There have been 46 major recorded floods on the river in historic times, the latest in 1870, and the worst in 1595. During the 1870 flood, water in some central streets of Rome stood up to nine feet; as a result, the river now flows between high stone embankments that completely control its course. (G. KH.)

**TIBERIAS** (Hebrew *TEVARYA* or *TEBARYA*), a town in Israel, lies 682 ft. (208 m.) below sea level, on the west shore of Lake Tiberias (Sea of Galilee), and 30 mi. (48 km.) E of Haifa. Pop. (1961) 20,792. The old black basalt town was largely rebuilt after 1922 and is famous for its hot springs and gardens. It is a lake port and market centre and, besides agriculture, has light industries and ironworks. Main roads link it with Nazareth and Haifa, Safad, and Beisan (Beit Shean).

The town takes its name from a refoundation on an older site, perhaps Rakkath, of a city built by Herod Antipas in honour of the emperor Tiberius; Herod made it his capital, but had difficulty in settling it, and it was not until the 2nd century A.D. that it became the centre of Jewish learning and the headquarters of the Sanhedrin (*q.v.*). The Mishna and the Palestinian Gemara or Talmud (*q.v.*) were edited there. After Byzantine and Persian conquests, Tiberias fell to the Arabs in 637 and became the capital of the Jordan district, famous for carpets, reed prayer mats, paper, and cloth. It was captured by the Crusaders in the 11th century, and Tancred made it his headquarters; it was recaptured by Saladin in 1187, and taken by the Egyptians in 1247. Later it fell into decay. In the 16th century Tiberias became part of the Ottoman Empire and was granted to Joseph Nasi (*q.v.*) by Sultan Suleiman the Magnificent in 1561. Nasi strove to establish a Jewish refugee settlement there, but the scheme collapsed before the intransigent attitude of the Muslim population and the unhealthy climate. In 1922 Tiberias became part of Palestine and in 1948 of Israel. The Arab population was largely evacuated and replaced by the maabaroth system of transitional villages set up in 1950. (M. V. S.-W.)

**TIBERIUS** (42 B.C.—A.D. 37), Roman emperor from A.D. 14, was stepson to Octavian (later the emperor Augustus; *q.v.*), whom his mother, Livia Drusilla (*q.v.*), married in 38 B.C. His father was Tiberius Claudius Nero, praetor in 42 and an opponent

BY COURTESY OF THE NY CARLSBERG GLYP.  
TOTER, COPENHAGEN

TIBERIUS AS A YOUNG MAN. MAR-  
BLE, FOUND IN EGYPT IN 1896

of Octavian in the "Perusine War" of 41–40. Tiberius bore his father's name until in A.D. 4 he was adopted by Augustus and became Tiberius Julius Caesar. After his father's death in 33 B.C. he came under Octavian's tutelage and was highly honoured by him, riding beside his stepfather's chariot in the great triumphs of 29 B.C. and accompanying him as a military tribune in the Spanish campaign of 26. In 24 he was given permission to hold magistracies five years before the regular age, and in fact became quaestor in 23, praetor in 16, and consul in 13, with a second consulate in 7 B.C. In this period he won some reputation as an orator, but his chief distinction was in military affairs. In 20 B.C.

he conducted an army to the Euphrates, received back the standards which the Parthians had captured from Crassus in 53, and installed a pro-Roman king in Armenia.

In 16 he was governor of Gaul, and in 15 with his brother Drusus (*q.v.*) he undertook the conquest of the central Alpine lands (see *RAETIA*; *VINDELICIA*). In 12–9 B.C. he was in charge of still more important operations in the valleys of the Sava and Drava rivers and brought into the empire the area later known as Pannonia. In 8 B.C. he took command in Germany, where Drusus had died the year before. Here too his campaigns were successful, and he transported 40,000 prisoners to settle in Gaul. In 7 B.C. he celebrated a triumph, and next year he was given the signal honour of tribunician power as colleague of Augustus, who also offered him a command in the east. At this point, however, despite Augustus' violent protests, he retired from public life and took up residence on Rhodes.

He was suffering from both personal resentment and frustrated ambition. In 11 B.C. he had been married to Augustus' daughter Julia, after the death of her husband Agrippa. But he had been devoted to his previous wife, Agrippa's daughter Vipsania, who had borne his only son, Drusus (see *DRUSUS CAESAR*); and Julia refused to live with him as his wife once their only child had died in infancy. He claimed that she regarded him as beneath her, and it was clear that the emperor's intended successors were her children by Agrippa, Gaius and Lucius, whom Augustus had adopted as his sons. Tiberius said later that he had retired to avoid obstructing the boys' advancement, and indeed it was precisely in 6 B.C. that Gaius, aged 14, was chosen consul by the people (though Augustus did not allow him to hold office for another six years).

On Rhodes, Tiberius retained his tribunician power until its expiry in 1 B.C. and was visited by Romans of importance, including Gaius Caesar himself in A.D. 1. But friction with Gaius developed; and Tiberius, now in fear of his life, was only with difficulty able to persuade Augustus that he should return to Rome as a private citizen in A.D. 2. Then, however, his fortunes changed. Lucius died in A.D. 2 and Gaius in A.D. 4, and Augustus had to adopt Tiberius as his son and successor, though Tiberius in turn was made to adopt his nephew Germanicus (*q.v.*), who was married to Augustus' granddaughter Agrippina and was descended from Augustus' sister. Tiberius received tribunician power again and returned to commands of the highest importance, first in Germany (A.D. 4–5), then to crush a great revolt in Pannonia (6–9), and then in Germany once more after the defeat of Varus. In 12 he celebrated another triumph and in 13 was given authority to administer all the provinces conjointly with Augustus. When Augustus died on Aug. 19, A.D. 14, Tiberius was unmistakably the next ruler and already possessed most of the necessary constitutional prerogatives.

Augustus' surviving grandson, Agrippa Postumus, a possible

rival since he had been adopted along with Tiberius in A.D. 4, was promptly executed. But Tiberius put up a show of reluctance for empire, and it was not until Sept. 19 that the Senate formally conferred the other insignia of imperial power. Mutinies in the armies in Pannonia and Germany followed, but they were occasioned by grievances over conditions of service rather than by disloyalty to Tiberius personally. The first serious trouble for the government came in 19, when Germanicus, now the heir apparent, died in Syria. Tiberius had appointed Gnaeus Piso, a senior ex-consul, to keep watch on his nephew's work in the east, and the quarrels between the two men led to the accusation that Germanicus had been poisoned. Piso was tried and committed suicide, since he found Tiberius implacable on the charge that he had engaged in civil war. But though the poisoning had not been substantiated, the death of Germanicus was laid by many to Tiberius' account, and Germanicus' widow, Agrippina ('the Elder'), never forgave him. The situation was worsened when in 23 Tiberius' own son, Drusus, died. The elder sons of Germanicus, Nero and Drusus, were now advanced as possible successors to Tiberius, but Sejanus (*q.v.*), prefect of the praetorian guard, was meditating his own plans. In 29 his gradual attacks on Germanicus' party culminated in the arrest of Agrippina and Nero, the latter of whom was executed in 30 or 31; meanwhile Drusus, too, had been imprisoned. But in 31 Tiberius came to suspect Sejanus, outmaneuvered him, and had him put to death. The bloody vengeance taken on Sejanus' supporters did not end the attack on the friends of Agrippina, who herself perished by starvation in 33, soon after the death of her son Drusus in prison. In 36-37 there was a further series of executions of prominent Romans, perhaps connected with intrigues by the new praetorian prefect, Macro, to secure the succession of Gaius (Caligula), Germanicus' surviving son. When Tiberius died on March 16, 37, he was execrated by most of the aristocracy, and the people too shouted "Tiberius to the Tiber."

Indeed the people of the city had little cause to love an emperor who had been economical with public funds and had shown little interest in games or festivals. Moreover, in 26 he had left Rome and retired to Capreae (Capri) and had issued instructions to the Senate by letter. Yet his administration of the empire, though unadventurous, had been careful and thorough to the last. His declared policy was to follow Augustus in all things, and for him this implied a refusal to extend the frontiers, the avoidance of divine honours for himself, a rigid surveillance of provincial governors (some of whom had their tenures prolonged to exceptional lengths), and a readiness to assist genuine distress. He recalled Germanicus from the Rhine in 16, insisting on abandoning any aggressive action in Germany. Revolts in Africa (A.D. 17-24), Gaul (21), and Thrace (21 and 26) were suppressed without any need for the emperor to take the field. Armenia was given a pro-Roman king in 18, and as late as 35 Tiberius was again able to assert Roman authority against Parthia by appropriate instructions to his legate in Syria. In the Danubian provinces his reign was conspicuous for the building of roads and for the consolidation of the new province of Moesia.

The problem of Tiberius is inseparable from the problem of the veracity of the historian Tacitus, who wrote the first six books of his *Annals* about 80 years after Tiberius' death. To Tacitus, Tiberius was a bloodthirsty tyrant, cunning at first in concealing his hatreds and his lust for power, but coming out in his true colours once restraining influences (such as that of his mother) were removed. Tiberius' exceptional deference to the Senate is therefore treated as a sham, and the keynote of the reign is the use of the famous treason law (*lex maiestatis*), the operation of which was familiar to Tacitus from Domitian's reign (81-96). Yet in fact Tiberius intervened to check the more trivial prosecutions brought under this law, which in any case was instituted in the form known under the empire not by him but by Augustus. Moreover many of the numerous senators and knights who were executed under Tiberius were involved in serious charges of conspiracy or of tampering with the army; most were associated with the major political struggle which centred on the parties of Sejanus and Agrippina. Tiberius' patience was ex-

hausted when in 31 he thought Sejanus had betrayed him, and it may be that his mind became estranged. In earlier years he shows no signs of vindictiveness.

Nevertheless Tiberius' attempt to restore the traditional authority of the Senate was a failure. He was without the geniality which had brought Augustus his friends. Though tall and distinguished looking, he suffered from a skin disease of the face which made him embarrassed in public; moreover even his walk conveyed the haughtiness traditionally associated with his family, the Claudii. In addition, he was tactless and pedantic, and his tortuous speeches seemed to imply lack of frankness. Stories of his sexual excesses on Capreae (found in the biographer Suetonius rather than in Tacitus) may be discounted, but the retirement was certainly a mistake, for it lost him the personal contacts without which no emperor could successfully cooperate with the Senate. The death of his son Drusus was a misfortune, but in the struggles over the succession he might have found more sympathy had he not withdrawn into pure administration.

**BIBLIOGRAPHY.**—Apart from contemporary flatterers like Velleius Paterculus, most ancient writers (the Jew Josephus is an exception) were hostile to Tiberius. Rehabilitation set in early in the late 19th century; see for instance L. Freytag, *Tiberius und Tacitus* (1870); E. S. Beesly, *Catiline, Clodius and Tiberius* (1878). It has been continued more recently by many writers: see F. B. Marsh, *The Reign of Tiberius* (1931); M. P. Charlesworth in *Cambridge Ancient History*, vol. x, ch. 19 (1934); E. Ciaceri, *Tiberio* (1934); D. M. Pippidi, *Autour de Tibère* (1944). Latterly the Tacitean tradition has been strongly reinforced by R. Syme, *Tacitus*, 2 vol., esp. ch. 30-32 (1958); and Tiberius' defects are studied from a medical standpoint by G. Marañón, *Tiberius: a Study in Personal Resentment*, Eng. trans. by W. B. Wells (1956). For contemporary documents see V. Ehrenberg and A. H. M. Jones, *Documents Illustrating the Reigns of Augustus and Tiberius*, 2nd ed. (1955); on Tiberius' portraiture, E. Hohl in *Klio*, vol. xxi, pp. 269-284 (1938); R. S. Rogers, *Criminal Trials and Criminal Legislation Under Tiberius* (1935), is an important (pro-Tiberian) study of the treason law. (G. E. F. C.)

**TIBERIUS II (CONSTANTINUS)** (d. 582), Byzantine emperor from 578 to 582, was a Thracian who served against the Avars in the Balkans. In 574 he was adopted by Justin II and shared the regency with the empress Sophia until in September 578 he was crowned emperor by Justin during one of the latter's lucid intervals. As emperor he inaugurated a lavish policy, leaving an empty exchequer for his successor, Maurice. Tiberius made a three years' peace with Persia (576-578) which did not, however, apply to Persarmenia. Here the Byzantines gained notable successes, and peace terms were being discussed when Khosrau I died (579). Under his successor, Ormizd IV, hostilities broke out again (579-581). On the northern frontier Tiberius attempted to pacify the Avars by an annual tribute, but in 581 had to surrender Sirmium (now Mitrovica, Yugos.). He was also unable to check the Slavs who were pouring south of the Danube into Thrace and Thessaly. In 582 Tiberius, now mortally ill, recognized Maurice as his successor and crowned him emperor on Aug. 13, the day before his own death.

**TIBESTI**, a mountainous region of the central Sahara, mostly in the northwestern corner of the Republic of Chad. It extends SE-NW for about 300 mi. (480 km.) and its greatest width is 175 mi. (280 km.); it includes the highest summit of the Sahara, the volcanic massif of Emi Koussi, which reaches 11,204 ft. (3,415 m.). The eruptive rocks have forced their way through a substratum of crystalline rocks covered by horizontal Paleozoic sandstone, the scarp of which is quite brusque above the surrounding plains, which are hundreds of metres above sea level.

Three great dry watercourses, deeply cut into the massif, indicate a climate that was formerly more humid. The daily variations of temperature reach 30° at times. The Tibbu inhabitants, at most 8,000, are chiefly nomads, although there are some sedentary elements.

Tibesti was partly explored by Gustav Nachtigal in 1870. After that no European went there until 1915, when Col. Jean Tilho wrote a description of it and mapped it. (J. D.)

**TIBET**, a country of central Asia, annexed by the People's Republic of China in 1951 and since regarded as an autonomous region of China. Tibet is called by Tibetans Bod (Bodyul), by Indians Bhot, by Mongols Tobet and by Chinese Tufan and Hsits'ang. Area 471,660 sq.mi. (1,221,601 sq.km.). Pop. (1957 est.) 1,270,000. The inhabitants are scattered on a mountainous plateau extending approximately from 74° to 100° E. long. and from 27° to 37° N. lat.

Culturally Tibet includes parts of the Chinese provinces of Szechwan, Kansu and Yunnan, and part of Jammu and Kashmir (*qq.v.*). Although the people in this vast area differ ethnologically, in customs, dress and dialects, they have a common written language. Lhasa, the capital of Tibet, is the mecca of Tibetan Buddhism. Before Outer Mongolia and China fell under Communism, pilgrims flocked to the holy city from remote Manchuria and Mongolia, some even from the U.S.S.R.

Historically, Tibet has on occasion ruled and has long influenced the frontier states of Nepal, Sikkim and Bhutan on the southern slopes of the Himalayas. From the 13th century until 1951 it was ruled by a religious hierarchy and the dalai lama (*q.v.*) wielded temporal power. In the 17th century the head of a reformation Buddhist order, Gelugpa (called in the west the Yellow Hat), achieved political ascendancy. He was officially acknowledged by the Chinese emperor as the dalai lama. In 1911 China became a republic, and during the years of civil wars and internal dissension that ensued Tibet, with the encouragement of the British, openly defied Chinese overlordship. Though nominally under Chinese sovereignty or suzerainty, Tibet was, to all intents and purposes, an independent nation from 1913 to 1950. In 1950 Communist China invaded Tibet, which capitulated and signed an agreement in Peking in 1951. However, sporadic revolt against Chinese rule immediately broke out. Even the announcement by the Communist regime in 1957 that it would not attempt to introduce any "democratic reform" in Tibet during the second five-year-plan period (1958-62) did not bring about the desired pacification, for the Tibetans resented outside interference. The crisis came to a head in March 1959 with a mass revolt against the Chinese occupation forces. This was ruthlessly crushed and culminated in the flight of the dalai lama to India.

### PHYSICAL GEOGRAPHY

**Geology.**—The Tibetan plateau was an ingression area of the Mesozoic and the Cenozoic eras and is geologically very young. Millions of years ago there were no mountains and the whole area was a huge sea. The Himalayas, the world's highest mountain mass, were uplifted in the course of ages and are still growing. The horizontal strata of conglomerate rock are composed of pebbles, pressured together through time, and limestone, containing marine fossils. The lakes in the Chang Thang area are the remnants of the ancient sea. This Cenomanian transgression did not extend to the Kunlun complex which is much older than the Himalayas. The Kunlun is composed essentially of Devonian limestones and slates of the Paleozoic era while the metamorphosed limestones and quartzites of the Himalayan ranges were classified as Jurassic. It is probable that during the glacier periods the whole highland was covered with ice sheets. The Pleistocene deposits are enormously thick in many places; an estimated deposit of 3,000 ft. was formed in the upper Sutlej valley.

**Physiography.**—Tibet is on a high plateau surrounded by mountain masses. In Tibet proper the mountain ranges run from northwest to southeast with deep or shallow valleys forming innumerable furrows between them. The lofty Himalayan chain sprawls along the entire southern frontier and shuts off the warm monsoon from the Indian ocean.

The great Himalayas extend over 1,500 mi., and to their north four other ranges stretch across Tibet: the Ladakh, the Kailas range (*q.v.*) or Trans-Himalaya (in Chinese Kang-ti-szu Shan), the Karakoram range (*q.v.*) and the Kunlun (*q.v.*) or Kuen-lun. The highest point of the Ladakh range is Gurla Mandhata (25,354 ft.), 12 mi. S. of Lake Manasarowar. North of Manasarowar the Kailas range contains a crowded cluster of peaks, several of which exceed 20,000 ft. The Kunlun range, extending from longi-

tude 77° to 93° E., forms the northern border of the Tibetan protuberance (*see also* HIMALAYAS).

In eastern Tibet the mountain ranges transverse from north to south. The meridional chains for many years steadfastly resisted the penetration of Chinese culture into Tibet, but they permitted the beneficial moist air to flow northward along the riverbeds of the Yangtze, Mekong and Salween, into the deep ravines and broad valleys cloaked with vegetation and extensive forests.

Most of the large rivers of Asia rise in the Tibetan highlands. The Yangtze has its uppermost source south of the Wu-lan-wu-la (Ulan Ula) range. The Mekong and the Yellow river rise on the eastern fringe of the Thanglha Ri (Dangla range). The Salween rises north of Lhasa near Ngachuka, and the Irrawaddy has its origin near the eastern tip of the Kailas range. The Indus, Sutlej and Brahmaputra all rise in the deep valley south of the Kailas complex near Lake Manasarowar. The Brahmaputra (Tsangpo) is the longest river inside of Tibet and flows for 800 mi. before entering India. Many tributaries swell its stream in its course: Kyi Chhu and Giamda from the north, Nyang Chhu from the south and Yigrong and Nagong from the east.

Between the Kailas and the Kunlun ranges is Chang Thang, an extensive lake basin studded with innumerable lakes. This lake region covers two-thirds of the territory of Tibet, but three of the largest lakes of geographic Tibet, Koko Nor, Manasarowar and Yamdrog Tsho, lie outside of it.

**Climate.**—The precipitation in Tibet decreases from south to north, because of the increasing distance from the ocean. The Himalayas capture most of the rainfall of the summer monsoon and on the southern slopes it often reaches 200 in. annually. A little rain may get through the mountain passes but is deposited on the Kailas range, beyond which is a region of extremely arid climate. The total fall of rain and snow over most of Tibet is less than eight inches per year. The temperatures are low because of the high altitude. Climate is generally rigorous. Its severity is much aggravated by the winds which blow with gale force during the greater part of the year. The temperature varies considerably in 24 hours, a climatic condition that differs little throughout the year. It is always bitterly cold in the morning and evening and the temperature usually drops below -18° C. (0° F.). At noon it may rise to 38° C. (100° F.) and the sun is scorching. Only during three to four months in the year is the Tibetan highland free from frost, and snow may fall in summer. However, in the lower land (under 12,000 ft.), in river basins and in southeastern Tibet, the climate is mild and pleasant. The air is dry, and, in the absence of dust storms, the sky is clear.

**Vegetation.**—In the expansive windswept, cold, dry, northern plain, comprising two-thirds of the area of Tibet proper, there are no trees. Average elevation is over 15,000 ft. (4,572 m.). In contrast, the Sutlej river valley in Ngari district and the Chumbi valley (*q.v.*) in southeastern Tibet have vast areas of virgin forests. Trees include giant conifers, varnish trees, spruce, fir, cypress, oak, walnut, maple and poplar. Cereals, mainly barley and buckwheat, are grown in the river valleys between the Himalayas and the Kailas. In the woodlands many medicinal herbs, in demand in China and India, are grown. *Peimu* (*Fritillaria roylei*), acanthus, rhubarb, saffron (*Crocus sativus*) and calamus (*Acorus calamus*) are some of the popular drugs found in Tibet.

**Animal Life.**—Domestic animals, raised mainly in eastern Tibet, include sheep, goats, yaks, horses and donkeys. The sheep provide the nomadic people of northern Tibet with skins for garments, and meat, milk and butter for food. The yak, a long-haired domesticated ox, is the typical draft animal and the chief means of conveyance for highland travel. It carries heavy loads (160 lb.) on bad roads, through steep passes and at high altitudes, but it cannot withstand the warmer climate and dense air of lower altitudes or be used for tilling land. Its meat and milk form the staple food of all Tibetans and its tail is highly valued in India. Herds of about 1,000 sheep and 200 yak are not uncommon.

The horse of eastern Tibet once famous for its small stature and stocky nimbleness has degenerated in the 20th century, so much so that the riding horses in Tibet now come from the steppes of Tsinghai province, China.

Among the wild animals found in Tibet the following are the commonest: wild yak, wild horse or ass (*kyang*), snow leopard, lynx, brown or black bear, wild sheep (*yuan*), gazelle (*goa*), antelope (*cho*), marmot and deer. The musk deer (*q.v.*), a hornless species, is found abundantly in eastern Tibet. The musk sac is a gland or pouch under the skin of the male deer's abdomen. Musk is dark-purplish or brown in colour, is unctuous to touch and has a remarkable permanence and stability of colour. Its scent is most penetrating and persistent, hence its importance for making perfumes. It is exported to Europe via India and China.

The common birds of Tibet are swan, stock or heron, hawk, gull, fishing eagle, bar-headed goose, raven, chough lark, sparrow, woodpecker and pigeon. The Tibetan chicken has an elongated body. Tibetan farmers raise poultry, but they eat only the eggs and not the meat. In eastern Tibet there are several rare and handsome varieties of pheasant.

### GEOGRAPHICAL REGIONS

The boundaries of Tibet were never clearly defined. The country is large and difficult of access. Lying on the borders are tracts of no-man's-land, or the habitats of roving bands of primitive natives. Tibet is generally divided into five main regions: U (pronounced Wei), Tsang, Ngari, Chang Thang and Kham. U, meaning "the centre," is both the political and cultural centre of modern Tibet. U covers the valleys of Kyi Chhu and Yarlung, two large tributaries of the Brahmaputra river. Both Lhasa and the ancient capital Yarlung are located in the U district. West of U is the Tsang district, of which Zhikatsé (Shigatsé) is the capital. North of Zhikatsé is the self-contained religious-political centre of Trashi Lhümpo. After the return of the panchen lama in 1952, his entourage, with Communist Chinese support, set up there a semiautonomous political organization, Panchen Kanpo Lija committee. (See *History* and *Administration* sections below.) Further west is Ngari, a sparsely populated highland with snow-clad mountains and deep river canyons, where the nomads drive their flocks and herds from one valley slope to another seeking scanty pasturage. Chang Thang, the vast windswept northern plain, is an inhospitable waste of frozen desert with few inhabitants. Of all the Tibetan regions, Kham, comprising eastern Tibet, is the most fertile and the most populated. Lower in elevation and with heavier rainfall, its river gorges are covered with extensive forests, and the lower river basins are cultivated. The eastern boundary of Kham was long disputed. The Tibetans held that Kham should embrace the whole territory extending from Taichao (Giamda) on the west to K'ang-ting (Tatsienlu) on the east; precisely the same area was designated by the Chinese government to form the province of Sikang. As a result armed conflicts occurred frequently in the first three decades of the 20th century. In 1933 a temporary settlement was reached to demark the border line along the north-south course of the Yangtze river. This line now forms the eastern boundary of the so-called Tibetan Autonomous region. East of the line was Sikang province, which in 1956 was transformed into the Kantse Tibetan Autonomous chow and became a part of the Chinese Szechwan province. Kham is under military occupation administered by the People's Liberation committee of Chamdo area.

### THE PEOPLE

**Racial Characteristics.**—The Tibetans are closely related to the aborigines inhabiting the mountains in western China. There are also numerous similarities between the Tibetan language and that spoken by the Shan (*q.v.*) and Kuki of northern Burma. The Tibetans are a homogeneous people with black hair, brown eyes and brown skin, and are sparsely scattered over an area from Ladakh in Kashmir to the northwest provinces of China. They divide themselves into three racial groups: Bodpo in central and western Tibet, Khampa in eastern Tibet and Amdo in northwest China. There are no appreciable racial differences in the three groups; all uphold the Tibetan Buddhist religion and use the same language. The people in eastern Tibet may be slightly taller. The chief difference is in culture. The people in central Tibet look down on the Khampa as inferior in culture, while the Amdo have

closer contact with elements of Chinese civilization.

**Language.**—The Tibetans possess a language which was reduced to writing in the 7th century, about the same time the Mahayana form of Buddhism was introduced into the country. The Tibetan alphabet is based on the Sanskrit alphabet in use in Kashmir at that time. The language is singularly refined. There is an honorific and nonhonorific word for each expression. Sometimes there are three distinctions: the most honorific used in addressing the highest lamas and the nobility, the less honorific to equals and nonhonorific to inferiors. Hence for a learned person there are three sets of vocabularies. Ability to employ the correct expression is a measure of one's standard of culture. (See also TIBETAN LANGUAGE.)

**Social Organization.**—There are three main classes of people in Tibet: nomads, farmers and townsfolk. The country is too high for ordinary agriculture; even pasturage is too scanty to sustain animal husbandry on a large scale. Few towns have populations exceeding 5,000 and Tibetans are designated according to the following occupations: clergy (lamas), nobility, traders, herders and peasants.

**Lamas.**—Prior to Communist Chinese domination it was estimated that about 20% of the population belonged to the clerical order. The priests of the Gelugpa order observed celibacy. Theoretically, the doors of the monasteries were open to all, and no age limit and no academic qualifications were set for entrance. Sons of the rich and of the poor, sons of the nobles and of the commoners were all admitted on an equal basis. However, monks from the upper classes had better chances for advancement because their wealth allowed them to pay fees and buy exemptions.

In Tibet there were no public schools; the monasteries were the only seats of learning. These were well organized and efficiently administered, and offered planned curriculums for student lamas. After completing a 16-year course a graduate was given the coveted title *geshi*. A *geshi* was respected throughout the country and was qualified to serve in the government or on the administrative board of the monasteries. Not all the enrolled lamas intended to acquire a serious education and many came for vocational training as calligraphers, printers, painters and craftsmen. A large number specialized in performing rituals for the sick. Groups were also trained as warrior-lamas and wore long hair, special uniforms and took vigorous physical exercises daily. They guarded the monasteries, enforced discipline, maintained public order during the new year festivals, acted as bodyguards to high lamas while traveling, and at the order of the abbot would take up arms against another monastery, against any private person, against foreign invaders or even against the government. Thus in one sense they formed a sort of national or home guard.

Monasteries obtained endowments from both the government and private persons. Government endowments may have included subsidies in kind, fund, real estate and even magistrate's districts. Private endowments included alms and donations in money and kind from members of the congregation or from outsiders. To this must be added interest and dividends on usury and trading, in which all monasteries freely engaged. The three large monasteries of Drepung, Sera and Ganden owned sizable real estate and enjoyed considerable autonomy.

The highest lamas were the "reincarnations" of whom there were hundreds, including the dalai lama and the panchen lama. (See TIBETAN BUDDHISM.)

**Nobility.**—There were about 150 noble families. The Tibetan nobleman traced his descent to one of three sources. The first could be from an ancestor who was ennobled for service to the country; the founder of the Pa lha family, for example, was a former Bhutanese priest of the 17th century whose work in the service of the Lhasa government was rewarded by the gift of an estate near Gyantse containing 130 farms. The second could be traced from a family in which a dalai lama or a panchen lama took rebirth; however lowly the family, it was ennobled and received large estates from the government; some of the leading Lhasa nobles were descended from brothers of earlier dalai lamas. The third class of the aristocracy was the oldest and smallest; its members traced their lineage to the early monarchs

who ruled Tibet before the 10th century. A rich commoner could apply for and be granted a nobleman's estate for which there was no heir.

**Traders.**—Petty trading was a side occupation of many people, and professional traders were few. Commercial transactions requiring long journeys were carried on by the men, while the women managed the shops and small retail trade. Nobles and monks alike engaged in trade. The large monasteries traded widely and had administrative departments in charge of trade. Chinese, Indians, Nepalese and Kashmiris also played a part in the commercial activities in Tibet. The most profitable items of trade, tea, wool, gold and rice, were formerly controlled by the Tibetan government; after Tibet's absorption into China these items became a monopoly of the State Trading company of Communist China.

**Herdsmen.**—The nomadic herdsmen and shepherds were hardy and independent, and pastured their flocks mainly in the uplands at altitudes of more than 14,000 ft., mostly in the high wilderness of northwestern Tibet. Some pastoral groups practised seasonal migration; during the winter they stayed in the lowland and in the summer grazed their animals on mountain slopes.

**Peasants.**—The peasants inhabited mainly the south and south-east. Women, in addition to their domestic duties, laboured in the fields with their menfolk. Some peasants worked as tenants for the government, monasteries, high lamas or noblemen, and the land was granted to them as family allotments in return for which they paid taxes and labour service. Some worked as drafted or hired labour, and the land was directly managed by the government, the monasteries or the nobility. Only a very small number owned and worked plots of land.

**Religion.**—In Tibet everything began and ended with religion. It is said the Tibetans would not die for their country but they would die for their religion. The early religion of Tibet was Bon (Bon-po or Pön). Buddhism was first introduced from India in the 7th century, at a time when it had degenerated into a corrupt form known as tantrism, with emphasis on magic and exorcism. For several centuries there was a fierce struggle between Bon and Buddhism, and the two faiths eventually compromised. Bon followers accepted the principal Buddhist tenets and even claimed the Buddha as one of their own divinities, while into Buddhism were incorporated many of the Bon deities and cult practices. The devil dance, which was performed in every Buddhist temple during the year's end for the purpose of expelling the evil spirits, was borrowed from Bon, as were the common practices of offering stones and hanging festoon flags over sacred spots. Tibetan Buddhism is commonly referred to as lamaism by westerners, a term not used by Tibetans, who always regarded their religion as unadulterated Buddhism; "lama" is a title of respect and may be used in referring to any priest or monk.

By the mid-11th century Buddhism gained ascendancy in Tibet, and new monasteries sprang up everywhere. Remnants of the Bon religion still exist among the herdsmen in Chang Thang and among the aborigines of Kongpo and the eastern Himalaya regions.

In the 13th century Tibetan Buddhism spread to Mongolia. A lama of the Sakyapa order converted Kublai Khan, who, after he became the emperor of China, made the head of that order the imperial preceptor and sovereign of central Tibet. This marked the beginning of theocracy in Tibet. With power grew the moral decadence of the priesthood. The priests indulged in mundane pleasures. Different religious sects struggled for power, and moral codes became degraded.

CHRISTA ARMSTRONG—RAPHO GUILLUMETTE  
TIBETAN REFUGEE IN INDIA HOLDING TRADITIONAL RITUAL OBJECTS OF LAMAISM, A PRAYER WHEEL AND ROSARY

In the 15th century there was a successful reformation movement led by Tsongkhapa, who advocated celibacy and abstention from intoxicants and worldly pursuits. The reformed order he founded, the Gelugpa, came to be called the Yellow Hat by westerners. Tsongkhapa and two of his disciples founded the three large monasteries of Drepung, Sera and Ganden, in Lhasa, and since the 15th century the abbot of Drepung has been recognized as the dalai lama. The abbot of Trashi Lhümpo monastery at Zhikatsé is the panchen lama. (See TIBETAN BUDDHISM and also History below; for Tibetan religious art see TIBETAN ART.)

**Customs.**—Shut off from the rest of the world for centuries by insurmountable mountains and tremendous gorges, the Tibetans developed peculiar customs and habits. They formed a small world of their own and fairly successfully resisted the penetration of outside influence until 1950 when the Chinese People's Liberation army began its drive on Tibet.

**Dwellings.**—The finest dwellings in Tibet were the mansions of the nobility. With the exception of a few minor nobles who lived in Zhikatsé and Sakya Gömpa, all the noble families maintained town houses in Lhasa. These were built of stone around a rectangular courtyard. On three sides of the courtyard were stables and storehouses; on the fourth side, opposite the gate, was the mansion itself, generally three stories high. The family quarters and chapel were located on the third floor where the rooms, unlike the dark and ill-ventilated rooms below, may have had glass windows and doors. The walls and the ceiling were painted with pictures and auspicious designs.

The common people lived in one- or two-story buildings. The roof was flat and made of clay like the earthen floor. Windows were plentiful, but glass was rare and the windows were covered by wax paper or other similar material, protected by strong wooden shutters. The houses of the village peasants were, as a rule, solid and substantial, with walls of stone or sun-dried bricks, though occasionally of clods of earth. Flat roofs of beaten earth were common throughout the Tibetan interior, but in the Chumbi valley and other rainy districts the roofs were gently sloped. Where pine trees grew, the roofs were constructed of pine shingles, kept in position by heavy stones. The herdsmen dwelled in tents of yak hair, rectangular in shape and ranging from 12 to 50 ft. in length. An aperture about 2 ft. in width along the middle of the roof let out the smoke. (See also LHASA.)

**Food and Drink.**—The staple diet of the ordinary Tibetan is yak's meat, mutton, barley flour, cheese and tea. Tibetans eat neither chicken nor fish. Those who dwell in the lower altitudes also eat rice, fruit and vegetables in small quantities.

The main beverage is tea. Brick tea from China is boiled in water flavoured with soda ash. When thoroughly boiled, the mixture is taken out with a ladle and poured through a strainer into a churn. Butter and salt are added and the whole churned until it is well mixed. The consumption of this beverage is enormous; Tibetans drink on an average 30 to 50 cups a day. The other chief beverage is a beer brewed from barley and only mildly intoxicating.

**Dress.**—The Tibetan dress consists of a very full gown with a high collar and long sleeves. The summer gown is usually of cloth made from goat's hair, but the wealthier classes may wear silk. The winter gown is sometimes of sheepskin, sometimes of cloth lined with lambskin or wadded cotton. Tied tightly around the waist with a woolen or cotton band, it is puffed out above, and in the capacious pocket thus formed are carried drinking cups and other odds and ends. For laymen the robe reaches to the knee, for priests and women to the ankle. In central and parts of eastern Tibet the women wear aprons, woven in varied colours and often so broad that they nearly meet at the back. Shirts are of cotton or silk; trousers differ greatly in shape from the western pattern and are of silk or cloth. The boot is of cloth, felt or leather, and of various colours. It rises to the kneecap, with a slit behind the knee, and is tied with gay-coloured woolen garters three or four feet long. Men's hats are of various kinds. In a few districts men wear necklaces. Earrings are very common and among the official classes universal.

The women of Tibet, especially those of the upper classes, display their headdress made of pearls, turquoise and coral on a

wooden frame. Herdswomen plait their hair into many tiny queues which are then bundled into a big one below the nape of the neck and adorned with red and yellow stones. Some women drape over their hair a large cloth sewn with silver and brass coins and shells which jingle at every step. The peasant women are physically strong and perform heavy manual tasks. When not tanned by exposure to the elements, Tibetan women are often fair, and those of the upper classes take great care of their complexions. In addition to the headdress, numerous ornaments are worn including rings, earrings, necklaces and girdles. The women wear charm boxes on the chest immediately below the throat. These usually contain a small image of a deity and a talisman written for the wearer by a lama.

**Family Organisation.**—Tibetan women, after marriage, held a comparatively high family status, but in religious affairs their position was lower. For instance, of the three forms of blessing accorded by the dalai lama to different suppliants (touching the head with both his hands, with one hand or merely with a tassel) the last and lowest form was the one used for all women. Although the Tibetan woman enjoyed a great measure of independence, she usually had little or no share in the choice of her husband. A son was consulted by his father as to the bride proposed for him, but the parents rarely consulted a daughter.

Priests of orders other than the Gelugpa were permitted to marry. Their wives were in charge of the lama's belongings, leaving their husbands free to devote themselves to religion.

Monogamy, polygamy and polyandry were all known in Tibet, though polyandry was the predominant form of marriage. The husbands were generally brothers, sometimes partners of a business. When a woman married the elder brother she married all the younger brothers as they became of age. A more unusual case was that of a widowed father and a grown-up son marrying the same woman. The preservation of the family estate seemed to underlie the marital oddities, for it was always the woman who controlled the family finance.

The aristocracy could marry only in their own class and this rule was strictly applied. Divorce was rare and had to be approved by the Tibetan government.

**Festivals.**—The Tibetan year was marked by numerous saints' days and festivals in which both lamas and laity took part. In addition to the great national holidays, each locality had its own particular auspicious days on which the tutelary deities were worshiped and local religious ceremonies were performed. The 8th, 10th, 25th and 30th days of each month were considered especially auspicious, as were the days of the full moon and the new moon. On these last two days the people made their way to the local monastery, clad in gala robes and carrying offerings of flowers, incense and money. Butter was also presented for the sacred lamps on the altar. The presentation of offerings to the gods is followed by prostration before the altar and the performance of devotions. Birthdays are unimportant dates in Tibet; they are generally not known and never celebrated.

The most important yearly event was the New Year or the great prayer festival at Lhasa. Commencing on New Year's eve, which usually falls sometime in February according to the Tibetan-Chinese lunar calendar, the ceremony and celebrations lasted the greater part of a month. First, houses and doorways were decorated with juniper boughs; puddings were prepared and a stock of wine laid in. The people passed the time in eating, drinking, dancing, singing and all kinds of merrymaking, combined with prayer when they felt so inclined. On the morning of the third day began the great prayer festival (*Monlam Chempo*).

From the dawn of the new year, monks from the neighbouring monasteries began to pour into Lhasa. By noon thousands of priests had assembled. The next ten days were occupied by religious services, held thrice daily in the great temple of Lhasa. The festival of lights was performed on the 15th day of this month. All the local monasteries and larger houses in the district were illuminated with thousands of small butter lamps. The 20th day marked the commencement of sports, and one of the most important events was horse racing.

During each year's prayer festival, the civil authority of Lhasa

was turned over to two proctors of the Drepung monastery. After an impressive installation ceremony at the public square, the proctors appointed their own staff and policemen whose principal duties were to maintain order. But the lama magistrates also collected business taxes and inspected private abodes. Heavy fines were imposed for uncleanness and disorderly conduct. Invariably the proctors derived a sizable fortune from the fines during the great prayer festival, which lasted 21 days. It provided also an opportunity for financial gain for the other lamas because three services were held daily during this period and after services alms were doled out to the congregation by rich patrons.

The daily services during the great prayer festival were conducted by the chief abbot of the Ganden monastery who is considered the successor of Tsongkhapa. On the 15th day the dalai lama conducted a sermon himself and bestowed benedictions to the multitude.

## HISTORY

Prior to the 7th century A.D. Tibetan history is wrapped in myth and legend. According to the orthodox tradition, the forefathers of the Tibetan people were a monkey and an ogress. However another story relates that in the very beginning the void gave birth to a most wonderful egg. When it burst open five months later, space, heat, fire, oceans and mountains issued from it; and from its very interior came forth man.

Tibetan histories usually refer to the division of the Tibetan people into four or six tribes or clans. The most ancient accounts give Shipuye or Pugye as the first king of Tibet, but the later Buddhist chronicle of central Tibet depicts Tibetan royal genealogy as commencing with Nyakhri Tsanpo, the son of an Indian king whose name varies in the different texts. After the first king, five groups of kings are: seven heavenly *Khri* ("thrones"); two upper *Teng* ("high ones"); six middle *Legs* ("good ones"); eight earthly *De* ("worldly"); and four lower *Tsan* ("mighty"). With some slight difference, this system is essentially the same in all the chronicles. During the time of Shipuye the principal metals were discovered, agriculture and irrigation were introduced, the great castle of Yarlung was built and the Bon religion arose. After the mythical series of kings, Namri Sontsan appears as the first historically identified ruler. He conducted expeditions to western China, northern India, Nepal and even faraway Persia.

**Early Kings.**—In the 7th century Tibet was not a unitary state. Independent chieftains continued to maintain a great deal of power and constituted a strong and warlike nobility that furnished many generals and ministers to the state. In their turbulence they often revolted against the royal authority. Rivalry between individual chiefs was common and the struggle was mainly within the state for predominance in the government. The principal offices in the court were hereditary. The nobility, who held landed property, constituted the real power outside the court. Songtsen Gampo (620-649) and Khrisong Detsen (755-797) are two famous kings. The former is credited with the invention of Tibetan writing and the introduction of Buddhism. The most important personalities under his reign were Thon-mi Sambhota, his envoy to India, and Gardon Tsan (d. 667), his capable minister. Tibetans came into contact with Chinese, Nepalese, Turks and the people of Khotan and Kucha, and a little later with the Arabs. The petty kingdom of Namri Sontsan grew in less than a century to be a major central Asian power. During the reign of Khrisong Detsen, Tibetan power reached its peak and Buddhism was affirmed as the chief religion of the state. Padmasambhava, a famous tantric teacher, came to Tibet from Kashmir; the monastery of Samye was built and the first seven monks were ordained. Under this king Tibet gained prominence by military victories in its old struggle with the T'ang empire in China.

A third famous king, Ralpachan (815-838), was the most fervent Buddhist who ever rose to the throne in Tibet. The peaceful nature of the king manifested itself in a lull in military activity. In his zeal for Buddhism the king gradually removed the aristocracy from positions in the court and filled their places with Buddhist monks. A real persecution of the old Bon religion seemed inevitable. All this contributed to a growing tension that ulti-

mately burst into revolution. In 838 a conspiracy was formed and the king was assassinated by two noblemen of the families of Sbas and Cog ro. The conspirators placed on the throne the elder brother of the murdered king, Lang Darma, a Bonist. Buddhist temples were closed and destroyed, and monks were forced to break their vows or flee. In 842 Lang Darma was murdered by a monk, but his persecution had inflicted a heavy blow on Buddhism.

#### Religious Renaissance.—

The old kingdom of Songtsen Gampo dissolved into a great number of petty local chieftaincies. The descendants of Lang Darma succeeded in founding a strong state in the west (Guge, Ladakh), but they could not exercise any effective power in central Tibet. During this period the Bon followers resorted to plagiarism, appropriating many Buddhist books which they claimed to have dug out from places where their ancient masters had hidden them. This removed many fundamental differences between the two religions and compromised the position of Bon, which eventually lost its own characteristics and became absorbed into its rival.

At this time the kings of Guge sent groups of young students to India to rejuvenate Tibetan Buddhism. The most notable of these was Rinchen Zampo (958–1055), who with his associates and pupils translated many Buddhist texts. The greatest event took place in 1042 when the great Bengali teacher Atisha (982–1054) was invited to Guge by its king. Atisha carried his evangelistic work far from the monastery Tholing, then the cultural centre of Guge, to central Tibet, including such places as Samye, Lhasa and Nyethang. During this period the Buddhists, like the Bon followers before them, claimed to have rediscovered many buried texts (*terma*). This new wave of translation and reintroduction of Buddhist texts gave rise to later orders rivaling the old order (Nyingmapa). The old order recognized Padmasambhava as its earthly master. The newer order, Kadampa, returned to Atisha and Rinchen Zampo; another new order, Kagyurpa, claimed descent from Tilopa, Naropa, Marpa (1012–96) and Milaraspa (1041–1123); yet another new order, Sakyapa, claimed the Indic Siddha, Virupa, as its first master. 'Brog mi (992–?), a famous translator, belonged to this order.

**Relations With the Mongols.**—During the 13th century Tibet was still divided among a number of chiefs, religious leaders and laymen who ruled by right of succession or of election over different territories. In 1239 Mongol troops attacked Tibet. In this perilous moment the Tibetans turned to Sapan (1182–1251), the abbot of Sakya monastery, who seemed to possess the greatest authority and influence in the whole country, and empowered him to deal with the Mongols.

Sapan's nephew, Phakpa (Phags-pa; 1235–80), was not only a Buddhist saint but a remarkable genius. While still in his teens he so much impressed Kublai Khan (1260–94), who had conquered the eastern part of Tibet and was soon to become emperor of China, that he was requested by Kublai to initiate him into Buddhism and was thus acclaimed the imperial preceptor. Phakpa also won a debate before the emperor over the Nestorians, Muslims and the Taoist theologians of China. Kublai made Tibetan Buddhism the national religion of his empire. At the age of 31 Phakpa was ordered to invent a writing system for the Mongols. He accom-

plished this task within five years, basing it on the Tibetan alphabet. But his composition did not prove satisfactory and it disappeared in less than a century without having been very widely used.

The Mongols made the abbot of Sakya the ruler of central Tibet and Tibetan Buddhism the national religion of China. Mongol rule in China was short-lived. The power of the Sakya hierarchy declined with the downfall of the Mongols, and Tibet soon fell a prey to anarchy. The nobility, taking advantage of disorder, often took arms to claim rights or avenge injuries. In these chaotic times, several rival religious sects emerged.

Toward the end of the 14th century a great religious reformation movement was gathering momentum in Tibet. Tsongkhapa was born about 1358 at Tsongka near Sining and came to central Tibet in his early teens; after a mixed education in the existing monasteries, he founded the Yellow Hat order (Gelugpa) and instituted a stricter code of morals. In 1409 he built the Ganden monastery.

Two of his renowned disciples were Gyethub (1364–1432) and Khedru (1385–1438); both were prolific writers. Other outstanding members of the Gelugpa were Jamyang Chorje, who in 1417 founded the monastery of Drepung, and Gyamchen Chorje, who in 1418 founded the monastery of Sera. Another disciple of Tsongkhapa, Gentun Drupa, was retrospectively recognized as the first dalai lama. His spirit was believed to have entered the body of a baby born two years after his death in 1474; this child became his successor, and thus began the system of priestly reincarnation which was of tremendous significance in later Tibetan history.

All through this period the fortunes of the various noble families and different sects of Tibetan Buddhism were intricately related. The Phamo Drupa family allied itself with the Drikunpa sect, rose against the Sakyapa hierarchy, won recognition from the Chinese emperor and took control of all central Tibet. Internal dissension in the 15th century broke its position, and its power devolved upon one of its subordinates. The succeeding family, Rinpung, seized Zhikatse in 1436 and gradually occupied the whole of Tsang. They in turn were replaced in 1556 by one of their subordinates, who had also started his conquest of Tsang from Zhikatse and who

became the ancestor of the so-called Tsangpa kings. The latter remained in power until 1642. Both Rinpungs and Tsangpa kings were patrons of the so-called Red Hat sect, Karmapa, a subject of the Kagyurpa order. During this period Tibet was torn by wars. Monasteries gradually succeeded in taking the upper hand, guiding the political life of Tibet. Landed property confiscated or seized when someone died without legitimate or recognized heirs passed into the hands of the monasteries. The centre of the struggle for power involved the Red Hat (Karmapa) sect, supported by the rulers of Tsang, and the rising Yellow Hat (Gelugpa) sect which opposed the Karmapa's corrupt formalism.

In 1566 the Ordos Mongols attacked Tibet and some captured lamas were taken to their chief, Altan Khan, who was attracted to the form of Buddhism preached by the Yellow Hat and who subsequently sent a mission to Lhasa. In 1577, upon the invitation of Altan Khan, Sonam Gyatso, the third reincarnated abbot of the Drepung monastery, visited Mongolia, converted the Mongolian chief to the Gelugpa faith, and received in return the title *Vajradhara dalai lama* ("holder of the thunderbolt," "ocean lama"). This marked the first time the reincarnated abbot came to bear the name dalai, a Mongolian translation of *gyatso*, "the ocean." Altan Khan died in 1582 and at the earnest request of the khan's son Sonam Gyatso visited Mongolia a second time. He died (1588) while on a journey to China.

After the death of the third dalai lama, the grandson of Altan Khan was selected as the reincarnation. The high priest's rebirth in a princely family of Mongolia served above all to weld together still more firmly the relations between the Gelugpa and its Mongol patrons.

At the beginning of the 17th century the chief of Tsang extended his power and occupied Lhasa. The fourth dalai lama had to seek safety in Samye. It was through the insistence of the Gelugpa that a Mongol army entered Tibet in 1621 to induce the Tsang king to halt aggression. The Tsang king was defeated and besieged in Lhasa. Gelugpa leaders acted as peacemakers and retrieved most of the monasteries that had been annexed to Tsang's dominion as well as the monasteries that had been obliged to change their sect by the domination of the Red Hat.

In 1638 Gushi Khan, the chief of the Ölöt Mongols and upholder of the Yellow Hat, sent envoys to invite the fifth dalai lama, Ngag-Wang Lobsang Gyatso, but the invitation was not accepted. In 1641 the fifth dalai lama and his regent, with Gushi Khan's help, defeated the Tsangpa king. He moved from the Drepung monastery to the Potala, which he rebuilt on the ruins of a palace formerly occupied by King Songtsen Gampo. The Yellow Hat then held complete spiritual sway and temporal power over the entire Tibetan nation. The fifth dalai lama died in 1682, but his regent, Sanggye Gyatso, unwilling to desist from his task, concealed the death and ruled in his master's name. He consolidated the Tibetan unification and finished the work of building Potala palace.

The sixth dalai lama, Tsangyang Gyatso, was a romantic young man given to wine, women and song. He incurred the displeasure of the commander of the Mongol forces, Latsang Khan, who in 1705 deposed the dalai lama and replaced him with a candidate of his own choice. The deposed dalai lama died mysteriously. The interference of the khan was resented by all of the Yellow Hat, and representatives of the three monasteries of Lhasa went for help to the Dzungars, another Mongol tribe in Sinkiang. In 1716 the Dzungars swept down through the vast northern plain, defeated the Latsang Khan and sacked the monasteries. This caused direct intervention by the Manchu empire.

**Domination by the Manchu Empire.**—Tibetan relations with the Manchus (*see CH'ING*) had been established while the Manchu kingdom was still a dependency of the Ming empire. The western Mongols were instrumental in bringing about this relationship. In 1642 and 1644 the fifth dalai lama twice made overtures to the Manchus. In 1646, when informed of the Manchus' success in China, he sent a letter pledging allegiance. In 1651 the Manchu court sent an official invitation to the fifth dalai lama and to the panchen lama, Lozang Chogyen (1569-1662). The latter, using his advanced age as an excuse, declined, but the fifth dalai lama started for China in 1652 and won official recognition.

In 1713 the Manchu emperor K'ang-hsi extended his patronage to the panchen lama, Lozang Yeshe (1663-1737), proclaiming him *panchen ratna* (in Tibetan, *panchen erdini*, meaning "great pandit, the gem").

The Dzungars' invasion caused prompt reaction on the part of the Chinese emperor. In 1717 K'ang-hsi sent a small relief army which was trapped by the Mongols near Nam Tsho and annihilated. In 1718 the emperor, now acting against his counsellors' advice, sent a new army from Koko Nor and another from Szechwan. In 1720, having wiped out the Dzungars in Tibet, he put on the throne in the Potala a boy reincarnation from Litang as the seventh dalai lama.

In 1726 the emperor Yung-cheng dispatched a civil officer to Tibet to arbitrate a dispute among the Mongol generals. This marked the beginning of the appointment of the ambans (resident ministers). In 1750 the ambans killed the Tibetan regent. The people in their turn massacred the Chinese in Lhasa. The emperor Ch'ien-lung dispatched an army, restored Chinese authority and strengthened the power of the ambans.

In 1788 the Gurkhas, who had recently gained ascendancy throughout Nepal, occupied some Tibetan districts near the Nepalese frontier. Three years later they pillaged Zhikatsé. The Manchu government dispatched an army, composed partly of Chinese and partly of Tibetans, under Manchu leadership. This army marched through Tibet during the bitterly cold winter, defeated the Gurkhas decisively during the spring of 1792 and dictated peace terms within a short distance of Katmandu, the Gurkhas' capital. Suspecting also that the British, who were by then established in India, had helped the Gurkhas, the Chinese closed Tibet as far as possible to foreign influence. It was decreed that all foreign questions should be dealt with by the ambans, not by the Tibetan government.

In 1855 another, more successful Gurkha invasion occurred. The resulting treaty empowered the Gurkhas to establish an agency in Lhasa and other centres, gave them an annual subsidy of 10,000 rupees and extraterritorial rights. In return the Gurkha government undertook to aid Tibet if the latter were attacked by another nation.

At the time of the Younghusband mission (*see below*), when British troops entered Tibet, the 13th dalai lama (1876-1933) fled to Urga (Ulan Bator), in Mongolia, where he remained until 1907. In November of that year he arrived at Koko Nor on his way back to Tibet; he was invited to Peking by the Manchu emperor and arrived there on Sept. 28, 1908; after a brief sojourn he returned to Lhasa in Dec. 1909. During the period of the dalai lama's exile, China, aroused by the British action, was taking measures to strengthen its hold upon eastern Tibet. In April 1905 a revolt broke out in Bathang (Ba-an), and the disorders spread through southwestern Szechwan and northwestern Yunnan, where several monasteries were involved. Chao Erh-feng, viceroy of Szechwan, was appointed to subdue this rebellion. His drastic methods during the following four years temporarily brought order to eastern Tibet. In Jan. 1910 Chao marched into Lhasa with 2,000 troops. For a time his vigorous administration gave China effective control of Tibet. The dalai lama fled to India upon the arrival of the Chinese force and remained there about two years. In 1911 revolution broke out in China and Manchu rule was overthrown. The Chinese garrison in Lhasa, after days of riots and looting, was forced to withdraw. The dalai lama returned to Lhasa in 1912.

**Relations With the British.**—British official relations began in 1774, when Warren Hastings was in charge of the British East India company. The dalai lama steadfastly refused to receive any British emissary, so Hastings approached the other pillar of Tibetan Buddhism: he sent George Bogle to the panchen lama at Trashi Lhümpo, but because of some opposition from the Nepalese trade relations were not opened up as had been hoped. In 1783 a second mission, under Samuel Turner, was sent to the panchen lama and was able to obtain trading privileges for the Indians only.

When the Manchu empire became corrupt and tottering, it failed to give effective protection against the Gurkha invasion of Tibet in 1855 and looked on helplessly while its tributary states, Burma,

Sikkim, Nepal and Bhutan, were made dependents of Great Britain. In the spring of 1903 Lord Curzon, the viceroy of India, sent Col. Francis Younghusband with a small escort to Kampa Dzong, 15 mi. N. of the alleged frontier, to meet Tibetan and Chinese delegates in order to discuss the problems of boundary and trade, but they were unable to persuade the Tibetan government to undertake negotiations. At last, in Nov. 1903, Younghusband advanced to Gyantse. On Jan. 8, 1904, British forces on their way to Gyantse had reached Düna without encountering any armed resistance. On March 31, when they attempted to move beyond Düna, they were obstructed by Tibetans, and a bloody battle took place. After 16 engagements in which several thousand Tibetans lost their lives, the British reached Lhasa on Aug. 3. The dalai lama fled to Ulan Bator. The regent, national council and assembly entered into negotiations with the British which resulted in a convention between Tibet and Great Britain and in a treaty signed on Sept. 7, 1904, to which China was not a party. The main terms were: (1) the opening of two new markets to foreign trade, one at Gyantse and one at Gartok in western Tibet; (2) the abolition of trade duties between Tibet and India; and (3) Tibetan territory not to be ceded or leased to any foreign power. On Sept. 22, 1904, T'ang Shao-yi was sent to India by the Chinese government to negotiate with the British government in regard to Tibetan affairs. The resulting Anglo-Chinese treaty was signed on April 27, 1906. A year later, on Aug. 31, 1907, an Anglo-Russian convention was concluded. Under its terms Russia recognized the special British interests; the two powers agreed that neither would enter into negotiations with Tibet except through the Chinese government and that neither would send representatives to Lhasa. In Oct. 1913 a conference was held in Simla at which the Chinese republic, Tibet and Great Britain were represented. The convention provided for a division of Tibet for administration purposes into two sections, Inner and Outer Tibet. Inner Tibet was to be administered by China, while Outer Tibet was to be autonomous. But China repudiated the action of its commissioner and never signed this agreement. It was signed, however, by British and Tibetan representatives on July 3, 1914.

**Rivalry Between Dalai and Panchen Lamas.**—The dalai lama with his private church, the triumvirate of Drepung, Sera and Ganden, the two esoteric academies of Gyeme and Gyuto and the oracle of Naichung, formed the nucleus of the Yellow Hat organization. Tibetans refer to them as the Seven Great Symbols. The panchen lama, with his Trashi Lhümpo monastery at Zhikatsé, maintained a court and a separate organization exactly like those of the dalai lama but on a smaller scale. The panchen lama is considered an incarnation of Amitabha (Tibetan Erpame, "Buddha of the boundless light"), and the dalai lama an incarnation of Avalokitesvara (Tibetan Chenrezi, "the compassionate"). Theoretically, in the ranking of the living Buddhas, the former stood higher than the latter. But in fact the first panchen lama was originally only the teacher of the fifth dalai lama, who, out of gratitude to him, had declared him to be a reincarnation and had conferred on him the Trashi Lhümpo monastery with its enormous benefices.

During the intricate development of world politics in the 20th century, the dalai lama and the panchen lama became deeply involved. The panchen lama had for generations been supported by the Chinese as a rival to the dalai lama. In 1904 the ninth panchen lama took the absence of the dalai lama from the country during the Younghusband mission as an opportunity to contest the leadership of Tibet. He courted the favour of the invaders by signing a truce with them at Gyantse and later even visited Calcutta to solicit British support. But the British, who had succeeded in imposing a convention with the representatives of the dalai lama, preferred to deal with Lhasa.

Shortly after the return of the dalai lama to Lhasa in 1909, a sharp disagreement broke out over a proposal for a political reorganization between the Chinese and the dalai lama, who was forced to leave the country and took refuge in Darjeeling, India. The panchen lama this time carried the favour of the Chinese and for several months lived in the Potala, the dalai lama's palace. Following the revolution in China in 1911, the dalai lama was restored to power and retribution was immediately taken. The

landed estate of the Trashi Lhümpo monastery was forced to pay taxes directly to Lhasa, thus depriving the panchen lama of his source of income. The dalai lama in trying to be independent of China resorted to British influence and signed the bilateral treaty with them in 1914. The situation grew to be very uncomfortable for the panchen lama, who in 1924 fled to China with his retinue. In 1933 the 13th dalai lama died. Escorted by a strong Chinese contingent the ninth panchen lama planned to return to Tibet, but his health failed and he died en route in 1937.

The 14th dalai lama was born in Tsinghai (Amdo) in 1935 and discovered in 1939. A year later in the same province a boy reincarnation of the panchen lama was found by his followers. The Lhasa government announced shortly afterward that it had discovered two other claimants. The dispute prevented the Tsinghai reincarnation from being installed in Trashi Lhümpo, which was directly controlled by Lhasa. In the last days of the Chinese Nationalist government, the Tsinghai boy was officially installed as the tenth panchen lama at the Kumbum monastery in Tsinghai. When the Chinese Communists came into power, the entourage of the new panchen swiftly pledged their allegiance to the new masters of China.

**Chinese Military Occupation.**—The independence of India on Aug. 15, 1947, and the Communist revolution in China during 1948–49 marked a new era in Tibetan history. In early 1950 the Communist army reached the bank of the Yangtze river, just east of the Tibetan frontier fortress of Chamdo. Then in mid-Oct. 1950 the Chinese Communist army advanced into Chamdo, about 370 mi. E. of Lhasa, where Tibetan troops accepted defeat. In December the regent resigned to give place to the 14th dalai lama. The Tibetan government moved to the southern border of Tibet. The first official act of the 16-year-old dalai lama after coming to power was to grant a general amnesty to all political prisoners in Tibet. At the same time he appointed the minister captured at Chamdo to head a mission to Peking, to be followed by another mission under his commander in chief. On May 23, 1951, a Chinese-Tibetan treaty was signed in Peking, the essence of which may be summarized under four points: (1) Tibet was to retain its autonomy, with no change in the dalai lama's political system or in his status, function and power; Tibetan religion, monastic institutions and customs would be respected; (2) the old position that the panchen lama enjoyed in the time of friendly relations between the 13th dalai lama and the 9th panchen lama was to be restored; (3) the Chinese Communist government was to set up a military and administrative committee, with regional military headquarters in Tibet; the Tibetan army was to be reorganized and systematically absorbed into the Chinese Communist army; (4) Tibet's external relations were to be handled by the Chinese Communist government. On Aug. 17, 1951, the dalai lama returned to Lhasa, the city from which he had fled on Dec. 19, 1950. By this time three forces of the Chinese Communist army had entered Tibet simultaneously, one from Chamdo on the east, another from Koko Nor on the north and still another from Ngari on the west, to take over strategic garrisons in Tibet; a fourth party comprising administrative and technical staffs arrived via India.

Both the dalai lama and the panchen lama were given seats on the National Committee of the Chinese People's Political Consultative conference held in Peking on Nov. 1, 1951. In the spring of 1952, under the shadow of the Chinese Communist troops, the tenth panchen lama, now 15 years old, scored a triumphal entry into the Tibetan capital. On June 23, 1952, the panchen lama was entrenched on the throne of his predecessors in the Trashi Lhümpo monastery which had been without its spiritual leader for 28 years. In Sept. 1954 both the dalai lama and the panchen lama attended the first Chinese National People's congress in Peking, and in 1956 they toured India together as guests of the Indian government.

Britain transferred to India its relations with Tibet in 1947 and the British mission in Lhasa and two trading agencies were taken over by Indian representatives. In 1950 India, hearing of the imminent Chinese invasion, on the ground that military action might cause unrest and disturbance on the Indian-Tibetan border sent notes of protest to Communist China. India's objections were

summarily dismissed by Red China as an interference in Chinese internal affairs. On April 20, 1954, India signed an eight-year agreement with Peking to promote trade and cultural intercourse and to facilitate pilgrimage and travel between the two countries. Under the agreement India retained the right to establish trading agencies at Yatung, Gyantse and Gartok, and a number of other Tibetan towns were designated as markets for trade. No Tibetan representative participated in the negotiation, and the language of the agreement inferred India's complete recognition of China's sovereignty over Tibet.

For political consolidation and military buildup Communist China embarked on a program of extensive roadbuilding in Tibet, and hundreds of thousands of Tibetans were pressed into the work. The hazards involved in bridging high precipices and deep ravines apparently caused the deaths of many workers. Resentment was general. The lamas, who were always exempted from government conscription, especially hated the new masters because no special consideration was accorded them. Further opposition was aroused by the attempt to impose land reform on the feudal religion-dominated society. Insurrection first broke out in Litang and Chamdo in eastern Tibet and then spread to the Golok tribe in southern Tsinghai; local Chinese garrisons were attacked. Red Chinese retaliated by bombing the Litang lamasery and killing most of the inmates. The wanton destruction of their seat of worship further infuriated the Khambas, natives of eastern Tibet. Unable to defeat the Red Chinese by a frontal attack, they resorted to guerrilla warfare and frequently intercepted communications on the newly constructed highways. An announcement from Peking in April 1957 not to carry out "democratic reform" in the next five years and a promise to withdraw most of the Chinese military personnel in Tibet did not achieve the desired pacification. By the winter of 1958 the Khambas and Goloks had joined forces and moved into the Brahmaputra valley south of Lhasa. The trading route from Gyantse to Yatung was cut. The rebels, who were joined by many discontented Tibetans from central Tibet, moved from the Gyantse area toward Lhasa in Feb. 1959. The situation became tense. The commander of the Chinese Communist troops put pressure on the dalai lama to deploy the Tibetan army to suppress the revolt; the dalai lama refused. On March 10, 1959, an invitation to the dalai lama from the Chinese commander to a theatrical performance at the latter's headquarters was looked upon with suspicion by the Tibetans, who feared that their god-king might be seized and held as hostage. Led by the *Mimaung* ("people's committee"), Tibetans, overtly and under cover of a gigantic parade, prevented the young ruler from attending the banquet. As the Communist soldiers tried to break up the demonstration, riots broke out. Reinforced by Tibetan troops, the rioters stormed the Red garrison and the arsenal. Street fighting continued for five days. The Communist soldiers bombarded the dalai lama's summer residence and the Drepung and Sera monasteries, inflicting severe damage on the two ancient religious institutions.

The dalai lama, his family, three cabinet ministers and many high government functionaries escaped and sought refuge in India. In a statement on arrival the dalai lama denounced Communist China as having broken all its promises to respect Tibetan autonomy as provided in the 1951 agreement. The government of India granted the dalai lama and his followers political asylum. Communist China accused India of inciting revolts in Tibet, and relations between India and China became critical.

After the flight of the dalai lama, Communist China on March 28, 1959, decreed the dissolution of the Lhasa government. The country was henceforth to be directly administered by the preparatory committee for the Tibet autonomous region, and the panchen lama was named acting chairman. The panchen lama moved from Zhikatsé to Lhasa in the same manner as had his predecessor in 1910. He pledged full co-operation in suppressing rebellions and bringing about the socialistic transformation of Tibet. He attended the Second National People's congress at Peking on April 17, 1959, and participated in the election of Liu Shao-chi as the second president of Communist China. Both he and the dalai lama (*in absentia*) were elected to be the vice-chairmen of the said National People's congress.

On Oct. 21, 1959, the United Nations general assembly, by 45 votes to 9 (with 26 abstentions), approved a resolution which deplored the events in Tibet and called for Chinese respect for the fundamental human rights of the Tibetan people.

Reports of sporadic fighting continued to reach other parts of the world in 1960, indicating that the Chinese Communists were still having trouble with groups of rebellious Tibetans. By mid-1960 more than 17,000 refugees had fled from Tibet to India for sanctuary, attesting to the continuing wave of suppression in the mountain kingdom. Through the 1960s China continued to consolidate its control over Tibet. Thousands of Tibetans continued to flee to India and Nepal. The dalai lama remained in exile in India.

## POPULATION

No census has ever been taken of the population of Tibet. The Peking national bureau of statistics, reporting on the result of a general census carried out in other parts of China in June 1953, estimated the population of Tibet at 1,273,969. This figure may be assumed to be reasonably accurate since the Tibetan government had previously estimated the number of persons under Lhasa's jurisdiction as between 1,000,000 and 1,500,000. Many Tibetans live in the Chinese provinces of Szechwan and Tsinghai, and some in Kansu and Sinkiang. The principal urban centres are Lhasa, Zhikatsé, Gyantse and Gartok (*qq.v.*). The Chinese government estimates the total number of Tibetans in Tibet and in China as 2,800,000.

All indicators point to a declining population. High infantile mortality, lack of medical knowledge, prevalence of venereal diseases and the strains on the heart and lungs due to rarefied air account for the abnormally high mortality rate. In addition, the family practice of sending one male child out of three to join the clerical order and the marital system of polyandry where several men share one wife formed a kind of arbitrary birth control and further limited the growth of population. On June 20, 1960, the International Commission of Jurists in Geneva concluded an 11-month investigation of the Tibetan affair, and thereby announced Communist China guilty of genocide in Tibet in an attempt to destroy the Tibetan people as a religious group. The Peking government was accused of upholding a systematic policy of killing, imprisonment and deportation of anti-Communist Tibetans.

The extent of Chinese colonization is not known, but a statement issued by the exiled dalai lama in Nov. 1959 indicated a marked acceleration in Chinese colonization.

## ADMINISTRATION

**Dalai Lama.**—Prior to the Chinese conquest, Tibet was the last theocratic country in the world. At the head of the government was the god-king dalai lama who held both spiritual and temporal power. He was, and still is, believed to be the embodiment of the compassionate Bodhisattva Avalokitesvara (Tibetan *Chenrezi*). When a dalai lama died he was succeeded by a reincarnation, who was found by following the indications provided by the preceding dalai lama on his deathbed, the guidance given by the state oracle and the revelations derived from the mirage over the sacred lake Nam Tsho. The rebirth might be discovered only after a long search. Sometimes more than one boy fulfilled all the indications. In such cases a preliminary selection narrowed down the number of candidates to three, who were summoned to Lhasa. Their names were written on paper scrolls and deposited in a golden urn. After seven days of prayer the lot was drawn before the Buddha image in the central temple. The first name coming out of the gold urn was proclaimed that of the future ruler.

During the absence of a dalai lama, such as the interval between his death and the finding of a successor reincarnation or during the successor's years of minority, a regent was normally elected from among the highest lamas of Tibet, approved by a great assembly summoned by the government for that purpose, and invited to assume full responsibility for the government. The regent could also be appointed by the dalai lama before the latter's death. When the dalai lama attained his majority between the age of 16 and 18, the regent surrendered to him all governmental authority.

Under the dalai lama there were clerical officers recruited from the three monasteries and lay officers recruited from the nobility. Two first-class reincarnated lamas were responsible for the dalai lama's education. A lord chamberlain, with three assistants, was in charge of the dalai lama's food, daily living and religious ceremonies. Under the lord chamberlain a secretariat was formed. There was a liaison office between the dalai lama's inner court and the outside world, including the Tibetan government.

**Tibetan Government.**—The highest office in the Tibetan government was called *shor*. This could be either a clerical or secular organization, and headed either by the dalai lama or by a regent. *Shor* also had a liaison office either staffed by the clergy or headed by a prime minister who was an eminent nobleman or a member of the dalai lama's family. Under the *shor* was the cabinet (*kashag*), normally in the charge of four ministers (*shapes*). The leader of these ministers must be clerical, while the other three were secular. Under the cabinet was the secretariat headed by four monk officers and the finance office headed by four laymen. There was no organized law court and legislature in theocratic Tibet. The important business of government was handled by the 12 men mentioned above. A litigation case could be assigned to any government official and important cases entrusted to a committee by the cabinet. If the defendant considered he was unjustly condemned he could appeal to the dalai lama. Special offices of industry and agriculture, and tea and salt taxation were created in the beginning of the 20th century. A bureau for external affairs was established in 1926 but abolished in 1951.

There was a national assembly (*tsongdu*) which did not meet regularly; both the agenda and the summoning were beyond the power of the constituent members. The assembly was convoked by the order of the government to deal only with specific issues. The four cabinet ministers fixed the number of participants on each occasion, and only those whom they invited could attend. The assembly was composed of all state officials of and above the fourth rank, the abbots of important monasteries in and around Lhasa and certain members of the nobility. The cabinet ministers did not directly participate in the deliberations but sat in a secret chamber. The four grand secretaries and the four finance ministers presided over the conference. A motion was never put to vote. It was considered carried when all opposition was silenced. A resolution was submitted to the cabinet ministers and in turn transmitted to the dalai lama. When a resolution was found unacceptable, it could be referred back to the assembly for further deliberation, but such an occasion seldom arose.

The state owned most of the land, which could be granted to individual lamas or monasteries or assigned to different offices in the government for their maintenance. Family estates fell into two groups: one group was made up of granted estates which were perhaps given to the nobility and held by the male heirs of the families concerned, on the basis of one heir for one estate, and were indivisible and inalienable; the other group included the private holdings of the nobility and the small percentage owned by commoners. Eastern Tibet was ruled by hereditary noblemen who drew their incomes from the land cultivated by their subjects. On July 3, 1959, a program of reforms involving large-scale redistribution of land to the peasants and the abolition of feudal customs was announced in Peking. The estates of the temples and monasteries were not exempted from this land reform.

In 1951 the representatives of the Tibetan government signed an agreement with the Communist government of China in Peking (see above). Under this agreement the Communist authorities promised not to alter the existing system in Tibet and to respect the established status, functions and powers of the dalai lama. Tibetan officials of various ranks were allowed to hold office as usual, and the people of Tibet had the right of exercising national regional autonomy. In April 1956 a Preparatory committee for Tibet autonomous region was formally inaugurated. This committee had authority over the Chamdo Military commission, the Tibetan government under the dalai lama and the *panchen kanpo lha*; i.e., its jurisdiction extended over all the territories under Tibetan control before "liberation." The dalai lama was the chairman of the committee, and the panchen lama and Chang

Kuo-hua, the Peking representative in Lhasa, were the two vice-chairmen. After the flight of the dalai lama to India in March 1959, the committee was reorganized and the panchen lama was made acting chairman.

**Local Government.**—Besides Lhasa and its suburbs, which were under the charge of two local administrations, there were in Tibet eight regional governments, each under a governor. The most important of these was Kham, which comprised all of eastern Tibet. The governor of this region, stationed at Chamdo on the western bank of the Yangtze river, was given the rank of a cabinet minister. In 1950 eastern Tibet was occupied by the Chinese Communist forces and administered by a military commission. Under the jurisdiction of the regional governments were more than 50 magistracies. Most of the local areas were administered by both clerical and secular officers. Some local officers lived in luxury in Lhasa, while the local governments were in the charge of their private secretaries or stewards. Villages were administered by headmen.

## ECONOMY

The economy of Tibet is still in a primitive stage. The nature of the terrain, the lack of rainfall and the severity of the climate impose a serious limitation on the development of agricultural resources. Industry is practically nonexistent. Trade is negligible and mineral resources still await exploration. There is great livestock and timber potential, the principal drawback being the lack of modern transportation. After invasion by the Communist Chinese army in 1950 a few trunk highways were constructed. Subsequent surveys seemed to confirm the conjecture of explorers in the 18th and 19th centuries that the Tibetan plateau is rich in mineral wealth.

**Agriculture.**—Agriculture in Tibet is almost completely of the subsistence type. Without irrigation the country is too arid to grow crops, and cultivation is limited to river basins and the lowlands in southeastern Tibet. The soil is alluvial, often composed of sand blown by the wind to form a layer over gravels and shingles, and its colour is light brown or grayish, according to humus content, which is poor. As fertilizer, human excrement, cow dung ashes and sometimes the fine silt from flood waters are used.

Barley is the staple food of Tibet. Rape turnips and peas are also grown extensively. In lower altitudes wheat, buckwheat and millet are raised. Rice grows only in a limited quantity in the southeast section of the land. The Brahmaputra basin is the granary of Tibet and supports about 60% of the population. Whenever hill streams are available, water mills are used for the grinding of barley into flour. In the northern plain radishes and potatoes are grown sparsely.

In the 1950s the Chinese Academy of Science set up experimental stations at Lhasa, Zhikatsé and Chamdo. It was reported that barley of Shantung variety, spring wheat of northern China, cabbage, cauliflower, tobacco, hemp, tomatoes, sunflower and millet were suitable to the local soil and climate.

**Forestry.**—In Tibet the most valuable woodland is in the Kham district, though extensive forest-clad mountains are also found in the valley of the Sutlej river in western Ngari and in the Chumbi valley in central Tibet. The Pome area in Kham is estimated to contain 17,300 sq.mi. of virgin forests. In the late 1950s 30 kinds of trees including those of comparatively high economic value, such as varnish trees, spruce and fir were discovered. Conifers averaging 90 ft. high and some trees as high as 200 ft. with a girth of 5 ft. were reported, and the estimated total of forest timber resources in this part of Tibet alone was placed at more than 130,800,000 cu yd. Accessibility is the principal factor which controls the development of the forests in this region. Chayre (Dzayul) is another district known for its profuse primeval forests.

**Minerals.**—Prior to 1950 no systematic mineral exploration was carried out or permitted by the Tibetan government, and mineral resources were the subject of wide speculation.

A modern scientific investigation was conducted by Swami Pranavananda, an Indian who made surveys in the 1930s and 1940s in the Mount Kailas and Lake Manasarovar districts in

western Tibet. The specimens of minerals he collected were analyzed at Benares Hindu university. He discovered extensive goldfields in the district of Sankora; radium, iron, titanium and emery on the eastern shores of lakes Manasarowar and Rakas Tal; lead near Gemuk; arsenic and serpentine near Kungri-bingri pass; and large deposits of borax on the shore of Lake Tseti Tsho.

Following the capitulation of Tibet, the geological section of the Chinese Academy of Science dispatched investigation teams who reported the existence of many useful minerals including oil shale, asphalt, iron, magnesium, copper, lead, zinc, molybdenum, antimony, salt, soda, borax, glauber salt, sulfur, alum, mica, barite, graphite, talc, gypsum, jade and china clay. A belt of iron deposits was located on the western bank of the Mekong river stretching for almost 25 mi. S. of Chamdo. Graphite was obtained from Ningtsin, and coal was reported plentiful around Chamdo. Iron deposits were also found in the Thanglha range on the border of Tibet and Tsinghai, containing ore in concentrated seams, of high quality and extractable depth. Three rich crystal deposits were found in the glaciers of the Sane range. In addition, oil-bearing formations, a large reserve of oil shales, and coal mines were unearthed as well as valuable lead, zinc and manganese deposits. The iron and coal mines in the Ngachuka area were reported in production by the late 1950s.

**Water Power.**—The swift-flowing rivers and mountain streams of Tibet have immense hydroelectric power potential, especially the Brahmaputra. However, only one small hydroelectric plant at Lhasa generating 2,000 kw. was in operation in the 1960s. Communist China established a hydrographic station at Lhasa and ten substations in various parts of the country to measure the speed of the current and water level of the Brahmaputra, Kyi Chhu and Kyang rivers at different seasons.

**Industries.**—Industry in Tibet is almost entirely of the home handicraft type. The largest handicraft industry is the weaving of woolen cloth. The spinning is done by hand and weaving by a wooden frame loom. Many Tibetans do spinning in their spare time, and the weaving is done by women. The finished fabric is a kind of heavy coarse serge which, in addition to supplying the local needs, is exported to parts of China where there are Tibetan colonies. The second largest handicraft industry is carpetmaking, centred mainly at Gyangtse. Under the Communists the Lhasa power station was repaired and reinforced with three 360-kw. generators and in 1952 the Chinese army built an iron and woodwork-ing factory. A new thermal electric station was installed in Zhikatse. An automobile repair works began operation in 1957 and a tannery was built in 1958.

**Trade.**—The main product of Tibet is wool, and it formed the principal item of export, mainly to northern India and Bombay. A small quantity came to the United States for carpetmaking. The famous fine "shawl wool," known as cashmere, came from western Tibet. Other items of export were borax, salt, animals and animal products and medicinal herbs. Gold dust, important in the 18th century, dwindled to nothing. Some rock salt and borax were exported to Nepal, Bhutan and northern India.

Tea, the principal import, was imported in the form of bricks from western China. Tea bricks were packed in yak hides, which were not tanned but merely dried in the sun. Tea also served as a form of currency for a traveler in Tibet, as it was readily accepted everywhere and was convertible into butter, barley flour or the local currency. Other exports from China were brocades, silks, chinaware, enamelware, canned foods, shoes and socks, shearing scissors; from India, felt hats, cotton and woolen cloth, tobacco, indigo, glass and ironware, petroleum, firearms, dried nuts; and from Nepal and Bhutan came rice and dried fruits.

After 1953 Tibetan trade became a monopoly of the Chinese State Trading company. In India it is represented by a trading company owned partially by Chinese and partially by Tibetans.

**Finance.**—The Tibetan government, prior to Chinese domination, derived its revenue from taxes, from landed estates owned by the government and from public funds loaned to private individuals at interest. Because of the scarcity of money most taxes, including import and export duties, were paid in kind. The taxes were paid to the district (*dzong*) offices and to special tax col-

lectors who toured the country to assist with the collections. The district officers did not receive any salary from the central government but subtracted a percentage of the take. The landlords paid their dues in grain which was stored in government granaries. Cash, butter, oil and meat were sent to the revenue office in Lhasa. Other articles were stored in the office of the local government to be disposed of or sold as need arose. The tenants who worked on land directly controlled by the government paid poll taxes. The government also loaned its surplus to a privileged few—high government officials, priests and wealthy traders who made a profit by lending out the money at high rates of interest.

The chief expense of the government was the maintenance of the large monasteries in and near Lhasa. The government provided free breakfasts for thousands of lamas and spent large sums every year for building repairs, but a far greater amount was spent on butter, used as oil for the myriads of lights which were kept burning day and night. The government paid only a nominal salary to the civil servants. The landed nobility lived on the income of their family estate and worked for the government as a duty. Those families which had no male heir or whose heir was too young to serve were obliged to pay the government an exemption fee. Those whose private incomes were too meagre to meet the demands of public officials looked on gifts from interested parties as part of their remuneration.

The dalai lama had a private treasury and he owned some of the best landed estates in the country. He received offerings from pilgrims and from deceased persons and he shared the profit from wool and gold monopolies of the trade caravans. The accumulated treasures of his predecessors in the form of precious stones, diamonds, pearls, gold, silver and rare silks were part of his treasury. These had been hoarded for centuries and their value was incalculable. The expenses of the dalai lama consisted of the maintenance of his own household and private chapel, and gifts to his relatives and priests of the large monasteries.

Tibet had a currency system of its own, although much of its internal trade was transacted on a barter basis. The monetary unit, the sang, is a silver piece. The Tibetan government also attempted to mint gold pieces, but the mint was burned down after coining only a small number, which are much sought by collectors. There was no bank in Tibet before 1950. Wealthy families left their savings with reputable traders who paid them interest or a share of their trade profit. The Chinese have established branches of the People's Bank of China in Lhasa, Zhikatse, Gyangtse, Chamdo and Gartok, have extended both commercial and agricultural credit and have introduced the Chinese currency.

**Transport and Communications.**—Before 1950, traveling in Tibet was done in the most primitive manner, either on foot or on the backs of animals. It was the deliberate policy of the Tibetan government to balk modern means of communications in order to keep the country difficult of access by outsiders.

For trading the Tibetans relied on the centuries-old caravan routes, of which the most important were: Tsinghai (via Nag Chhu), Sikang (via Chamdo), India (via Kalimpong and Yatung) and Kashmir (via Gartok and Leh). Under the Communist regime a network of motor roads was planned. Several trunk lines were completed, notably the Tsinghai and Sikang highways, and many secondary lines are under construction.

**Air Transport.**—The first air communication between Tibet and the outside world was inaugurated in April 1956. The airport is located near Lhasa. There is unscheduled service with Chengchow via Jyekundo (Yushu). There are military airfields at Chamdo, Zhikatse and Gartok.

**Railways.**—There are no railways in Tibet. However, a ground survey for a new railroad was under way, having been preceded by an aerial survey. The projected railway will be 807 mi. long, with Sining and Nagchudong as terminals. It will pass through complicated geological and topographical regions and its average altitude will be more than 12,000 ft.

**Postal and Telegraph Service.**—There are about 50 postal and telecommunication stations in Tibet, including mobile units that serve remote border areas and geological, hydrological and construction teams.

**TIBETAN ART** is a religious art; it is an anonymous expression of the Tibetan religion, a form of Buddhism (see **TIBETAN BUDDHISM**). It is anonymous because the artists regarded their work as an expression of religious faith and, therefore, a meritorious act. Buddhist art in Tibet was a continuation of medieval Buddhist art of the Pala kings who ruled in north India around 750–1150 A.D. The art style is very conservative in that it follows definite rules which are described in the Buddhist canon (Tripiṭaka). The first paintings of this style are to be found in the cave temples of India. The earliest images came to Tibet in the 8th century A.D. Before this time there was no literature and, except for prehistoric images, no art in Tibet. Buddhism introduced into Tibet not only religion but culture, writing, art and other humanizing influences. Tibetan art should be discussed in order of precedence. Though there are innumerable images of the Tibetan pantheon, the painted scrolls or *thang-kas* are richer in iconographical material and yield more information on religious symbology.

**Banners (Thang-kas).**—These paintings, or embroidered or appliqued pictures, are usually hung in temples or at family altars, carried by itinerant lamas in religious processions or used to illustrate sermons. A sized canvas is stretched on a frame and then rubbed down and prepared for the paint. An outline or transfer is usually used. The colours are made of vegetables, flowers and minerals boiled or ground and held together by glue or a binder. The important details of the work, such as the faces of the deities and the religious inscriptions, are put in by the lamas. These paintings are mounted on a brocaded silk border; a flat stick is put at the top and a roller at the bottom. Sometimes a thin silk dust curtain is put over the canvas to protect it from the smoke of the butter lamps used in temples and on altars. The materials used are fine Chinese or Japanese brocades. The paintings are used essentially for meditation. There are several general types.

**Buddha.**—Surrounded by deities or lamas, the Buddha is depicted in episodes from his life and teachings. The saints are also shown in this way, preaching or teaching with their disciples.

**Assemblage of Divinities.**—This type is called *tsheg shing*, "assembly tree," and shows a cosmic tree arising from the waters, through the earth and up into the heavens. On its branches are shown the various deities of the pantheon. It varies among the principal sects.

**The Wheel of Life.**—*Bhavacakramudra* is the "wheel of transmigration." The Buddha explained this to his disciples as the conception of the idea of birth and death, judgment according to karma, and rebirth.

**The Intermediate State.**—This is a special type of banner, depicting the symbolic visions that occur to the deceased between the moment of death and rebirth in accordance with his karma, in one of the six regions depicted in the wheel of life.

**Mandala.**—Sometimes called the magic circle, this is usually geometric in design (an inner circle enclosed in a square with four entrances). Mandalas have always exerted a particular fascination because in them art, magic and psychology combine. C. G. Jung, Richard Wilhelm and Heinrich Zimmer have made interesting attempts at psychological interpretations of the mandala. There are two kinds: painted mandalas and sand or butter man-

dalas. The symbology of mandalas probably comes from the doctrine which teaches that by meditation and concentration the soul can obtain complete union with the divine. It is one of the means used by Tantric sects to achieve supernatural powers. The mandala is believed to be the "dwelling of the god." The deity resides in the innermost circle and by various incantations, offerings and disciplines, the devotee invokes and finally identifies himself with him. The mandala is also a symbol of spiritual power because the devotee achieves the power of the deity. Coloured sand mandalas are usually used for ceremonies of initiation. They are technically of the same type as the painted mandalas but are impermanent, being made on the ground and destroyed when the rite is over. Coloured butter mandalas are made for certain festivals and are used only for 24 hours and then destroyed.

**Horoscopes.**—These are banners with mystic symbols and diagrams. Chinese trigrams, signs of the zodiac, etc. They are used by the astrologer-lamas to prophesy the future according to the birth date of the person for whom the horoscope is cast. These are also painted on silk or paper, according to the wealth of the applicant.

**Great Teachers.**—Dalai and panchen lamas and their antecedents are depicted in historical or genealogical paintings, and some of these are attempts at portraiture. Related to these are the "Eighty-four Great Sorcerers" (Musée Guimet, Paris).

**Images.**—The earliest images seem to have been imported from China and Nepal. Images cast in the northern monasteries, even in comparatively modern times, show Chinese influence, while those cast in southern Tibet show Nepalese influence. They are of enormous variety; there are from 300 to 500 deities in the pantheon, depending on the sect and the number of local deities. The materials used are gold, silver, copper, bronze, stone, wood, clay, butter and agglomerated materials. These images are of all sizes; huge ones are used in the temples, smaller ones are used on family altars and others are carried about in little pocket shrines. The images are usually sculptured or cast in molds, or made by the *cire perdue* (lost wax) method and finished by hand. (See **SCULPTURE TECHNIQUES**.) A cavity is always left at the base of the image or at the back and this is filled with rolls of prayers or sacred relics. The image is then closed and consecrated by the lama. The contents are sometimes referred to as "sacred intestines."

Images are divided into two main types: the pacific and the angry. The pacific deities have mild, compassionate expressions and wear either simple monastic robes or elaborate princely robes with jeweled ornaments and crowns. These are the Buddhas and Bodhisattvas (potential Buddhas). Those of the angry group wear ornaments of skulls and carved human bones; they are called Dharmapala. Other images include fairies, heavenly musicians, astrologers, great magicians, the Great Teachers, dalai and panchen lamas and historical persons. Among the most interesting is a type called Yab-Yum ("father-mother"), which shows Buddhas in the embrace of their Shaktis or female energies. These symbolize the merging of Compassion (the male) and Knowledge (the female) and indicate the method and the way of attaining nirvana. There are also a number of grotesque images, such as winged or horned figures on mythical animals. Their origin, significance and dating are not known. They probably relate to the earlier Bon religion.

**Ritual Objects.**—Tibetan Buddhism developed a wealth of ritual objects. Among these are thunderbolts and bells, prayer wheels, magic daggers, rosaries, clay tablets and wood blocks. There are also butter lamps and bowls to hold incense, flowers and water. The eight auspicious Buddhist symbols, as well as musical instruments, are always in evidence. Some of the Buddhas hold the thunderbolt, symbol of power, or the bell, symbol of the void or emptiness of existence. The prayer wheel is a round metal case or cylinder which revolves on a stick and is filled with a roll of prayers. Each revolution of this wheel is a repetition of the *mantra* (q.v.) *om mani padme hum*. Magic daggers are used to exorcise evil. Ghost traps made of a framework of wood and surrounded by multicoloured threads are used to entangle evil spirits or demons, and prevent them from entering the home and injuring the inhabitants. Prayer flags and prayer stones serve the same purpose.

**Chronology.**—There exists, as yet, no infallible means of identifying any Tibetan art work on stylistic criteria alone. Works have not been grouped chronologically in dynasties or periods as in China. Dating is extremely difficult and, except when images are inscribed, unreliable. Since each type, gesture and symbol is prescribed in the canonical rules, it is practically impossible to differentiate an old from a more recent image. Images of historical teachers or dalai or panchen lamas, of course, cannot antedate the individual portrayed.

The dating of banners is controversial; rolled paintings or *thangkas* did not appear until about the 10th century A.D. Unless they are among the very few dated banners, such as the Lha-mo banners, it is difficult to assign them to a specific period. The banner of Lha-mo has an inscription in four languages—Chinese, Mongol, Manchu and Tibetan—"Made by command of the emperor Ch'ien-lung in the 42nd year of his reign" (A.D. 1777).

**Collections.**—At the Musée Guimet in Paris there are several paintings showing Gsen rabs Mibo, the prophet of Bon, and some of the Bon deities. In the American Museum of Natural History, New York city, there is also a large group of unidentified images. The most comprehensive collections of Tibetan art in the United States are to be found at the American Museum of Natural History, New York; the Newark Museum of Arts and Sciences, Newark, N.J.; and the University of Pennsylvania museum, Philadelphia.

Jung (1947); Heinrich Zimmer, *Myths and Symbols in Indian Art and Civilization* (1946). (A. K. G.)

**TIBETAN BUDDHISM.** This article deals with the special form of Buddhism (*q.v.*) which has gradually evolved in Tibet since the 7th century A.D., when Tibetan rulers first began to take an active interest in this religion. It is also convenient to include the pre-Buddhist cults (known as Bon), for very little is known of them in their primitive form, whereas subsequently they have been so affected by Buddhist beliefs and practices as to have become just a rather incongruous sect of Tibetan Buddhism.

**Lamas and Monasticism.**—Tibetan religion attracts interest in the west mainly on account of its special system of reincarnating lamas. There are several hundreds of them, of whom the dalai lama and the panchen lama are incomparably the most important (see DALAI LAMA). Lama (*bla-ma*) means simply "superior," and is the normal polite title for senior monks and for those in the villages who act as the "priests" of their small communities as well as for the heads of teaching faculties in the larger monasteries and the principals of religious institutions, both small and large. In the case of such senior lamas suitably respectful epithets are added, but the term itself is of wide application as the title "father" for a Christian priest. The reincarnating lamas (*sprul-sku*) are normally principals of monasteries and they have steadily increased in number since the 15th century (when the idea of identifying successors in this way gained general acceptance), for it greatly adds to the prestige of an institution to have an "incarnation" as its head. Nevertheless there still remain many institutions where other methods of succession are in vogue: by inheritance from father to son (in the case of married religious practisers), from uncle to nephew or by selection according to merit and learning. Of these last the abbot of Ganden (dGa'-ldan), one of the three enormous Gelugpa (dGe-lugs-pa) monasteries on the outskirts of Lhasa, is the most important.

The widespread monastic system itself is but an elaborate development of the type of monastic life which is fundamental to Buddhism in all its forms. What is remarkable is the zeal with which the Tibetans have taken to religious life; no census has ever been made in the country, but a quarter of the population are probably members of religious institutions, or at least were before the Chinese Communist occupation of 1950. Their religion serves as the basis of their whole culture.

**Early History.**—The first temples were built in the reign of Sroñ-btsan-sgam-po (or Songtsen Gampo; d. A.D. 649), who was also responsible for founding Lhasa as well as for establishing an official Tibetan alphabet based on the studies of one of his ministers, Thon-mi Sambhota, in Kashmir, which was then still a Buddhist country. Two of Sroñ-btsan-sgam-po's queens, one Chinese and one Nepalese, are popularly regarded as the earliest patrons of Tibetan Buddhism and thus identified as "incarnations" of the Buddhist saviouress (Tara). No spectacular progress was made with the new religion during the next hundred years, for the Tibetan leaders were engaged in conquering and controlling a huge central Asian empire, recognized under duress by the Chinese, from whom they wrested the important city-states of Kashgar, Kucha, Karashahr and Khotan on the ancient silk route, which skirts the Takla Makan desert. This brought them into contact not only with Buddhist communities but also with Manichaeans, Nestorian Christians, Arabs and Persians, followers of Islam. Central Asian Buddhism evoked active interest among the Tibetans: monks fleeing from Khotan were hospitably received by the Chinese wife (d. A.D. 739) of the Tibetan king Mes-ag-ts'oms, monasteries being built for them presumably near Lhasa; moreover large collections of Tibetan Buddhist manuscripts preserved at Tun-huang attest the existence of Tibetan religious communities in the area. It seems that the royal family was eager to foster Buddhism, while powerful ministerial chiefs were opposed to it. Royal authority was established during the long reign (755-797) of K'ri-sroñ-ide-btsan (Khrisong Detsen), notable for three major events: the building of the first proper Tibetan monastery at Samye (bSam-yas) between Lhasa and Yarlung; the ordaining of the first seven Tibetan monks; and the holding of a council to decide the relative merits of Chinese and Indian forms of Buddhism. The Indian masters Santarakshita, representing orthodox Mahayana teachings, and Padmasambhava, manifesting the magic powers of a *mahāsiddha* ("master yogin," of whom there are 84 in Shivaist and Buddhist Tantric tradition), were responsible for the founding of Samye; the views of Santarakshita's disciple Kamalashila prevailed at the council. Buddhist monks appear as ministers of state as early as the beginning of the 9th century. The third "religious" king of Tibet, Ral-pa-can (Ralpachan), who is credited with systematizing the methods of translating texts and with establishing the *Vinaya* (monastic discipline) of the Mulasarvastivadin order or of Indian Buddhism as the sole orthodox Tibetan one, was murdered (838) by his brother, who thereupon set about destroying the new religion, at least in the region of Lhasa.

**Bon.**—Explicit references to Bon occur in the cycles of quasi-historical texts concerning Padmasambhava, who is honoured as the chief queller and converter of all forces hostile to Buddhism. The character of original Bon beliefs can be surmised from such textual references, but, since literature began in Tibet as a deliberate Buddhist concern, with the whole wealth of Indian literary traditions behind it, the Bon-pos were bound to use Buddhist terminology, often without realizing perhaps that it implied ideas that might be specifically Buddhist. That they later tried to have recourse to Hindu mythology indicates the fundamental weakness of their position. The original features of Bon seem to have been a cult of divine kingship whereby the kings were regarded as manifestations of the sky-divinity; an order of oracular priests; a cult of the gods of the atmosphere, the earth and subterranean regions; and the practice of blood sacrifices. All these features in a transmuted form have been absorbed into Tibetan Buddhism. While Bon-pos and Buddhists must both have had their interested supporters in 8th- and 9th-century Tibet, the chiefs of the country seem often to have used them as factions in political intrigues.

**Tibetan Translations of Buddhist Texts.**—Royal sponsors appeared again in the 10th-11th centuries, this time in western Tibet (mNa'-ris), namely Ye-ses-'od and his brother Lha-ide, then the latter's sons, 'Od-ide, Byañ-c'ub-'od and Śiba-'od. They fostered learning and sent young Tibetans to India to study, of whom the most famous is probably the great translator Rin-c'en-bzān-po (Rinchen Zampo; 958-1055). Large sums were expended buying the services and knowledge of Indian masters. One of the most

The Bronhyd lotus, the perfect eight-leaved lotus flower with a silver urn in the centre. Below, the Bronhyd lotus with petals closed

Statuette of Yamantaka, the ferocious form of the Tibetan deity of wisdom, Manjushri, who waged war against Yama, king of hell. The deity is shown with 9 heads and 34 arms

Statuette of Changcha Hutuktu, a Living Buddha of Peking

### TIBETAN IMAGES AND RITUAL OBJECTS

A ritual vessel of gold, silver and copper inlaid with turquoise. It shows Chinese influence

Prayer wheels, cylindrical metal cases in which a roll of prayers, printed on paper, is inserted; the cylinder is mounted on a rod on which it is revolved. Left, a table prayer wheel; right, a hand prayer wheel

Statuette of Padmasambhava, an 8th-century Indian teacher, founder of the Old Translation school (the so-called Red Cap)

Representation of Lchang-skye Rol-pa' i rdo-je. Chinese influence is shown by the architecture of the monasteries. The saint carries a book, one of the attributes of his patron, the celebrated reformer Tsong-kha-pa, founder of the Yellow Cap sect of Tibetan Buddhism

# TIBETAN PAINTINGS

The Wheel of Life, pictorially explaining the Buddhist conception of life, death and rebirth. The wheel is held in the clutches of a demon who symbolizes impermanence. The drawing in the hub is symbolic of lust, anger and ignorance, cardinal sins. Different worlds of rebirth are represented in the segments of the wheel. In the outer rim are 12 scenes which dramatize the various stages through which man passes after birth

Gautama Buddha in the attitude of turning the wheel of the law. He is surrounded by Buddhas, Bodhisattvas and Arhants

renowned of these was Atisha (982–1054), who spent the last 12 years of his life in Tibet, surrounded by Tibetan disciples. From now on Buddhism seems to have had no determined opponents; the Bon-pos had already begun to produce their own literature on Buddhist models and were presumably often as interested in the latest Tibetan translations from Sanskrit as were the Buddhists proper. When one remembers that much of this work was done by individual practisers of the doctrine following their own bent in translating philosophical or doctrinal texts, tantric cycles and their manifold commentaries, works on medicine, astrology, etc., it is remarkable what uniformity was eventually achieved.

By the 14th century the Tibetans had succeeded in translating all available Buddhist literature in India and Nepal. After the destruction wrought in the name of Islam, Buddhism had practically disappeared from India by A.D. 1200, and Nepal (primarily the Katmandu valley) remained the sole representative of Sanskrit Buddhist culture. Practice of the doctrine rapidly began to deteriorate there, now that Indian inspiration was gone; meanwhile Tibet began to manifest itself as the chief inheritor of the whole Indian Buddhist tradition. No complete Indian canon of Mahayana Buddhism seems ever to have existed. But having collected and translated over the course of some six centuries all canonical and quasi-canonical texts, as well as the works of all Indian Buddhist writers, the Tibetans gradually produced their own canon, which had assumed by the 13th century more or less its present form. Consisting originally of a massive collection of manuscripts, this great work has appeared in several editions (printed page by page from incised wooden blocks) since the 16th century. It is arranged as 100 or 108 (depending on the edition) massive volumes of supposedly canonical texts (*Kanjur*, or *Kagyur*, "translated word") and 225 volumes of commentaries, scholarly treatises and miscellaneous writing by Indian masters (*Tenjur*, or *Tangyur*, "translated treatises").

**Later Developments.**—It has often been said that the Tibetans adopted only the more debased forms of Indian Buddhism, and the use of the term "lamaism" has been used (like papism) to suggest a curious and falsified form of original teachings. In fact they adopted the whole of Indian Buddhism with its monastic life, its scholarly disposition, its ideal of the beneficent sage and its more popular conception of the wonder-working tantric yogin. Thus there are religious men of all kinds in Tibet: the wealthy benefactor sponsoring a new community, the independent seeker after knowledge (and sometimes the wealth that such knowledge brings), the pious monk spending his whole life translating texts, or the converted Bon-po striving to gain those special powers associated with proficiency in tantric practice.

Thus the earlier orders of Tibetan Buddhism began to develop quite spontaneously around the traditions associated with certain revered masters, but with no deliberate doctrinal or practical differences to distinguish them. The Nyingmapa (rNin-ma-pa; "Old Order") claimed to transmit the original teachings of Padmasambhava, the great tantric master of the 8th century, who was now identified as a Buddha. In support of their doctrines they began to "discover" texts, which had been "hidden" during the persecution following the murder of Ral-pa-can. Many of these texts, which were put together in the 12th and 13th centuries, do in fact contain very ancient traditions. The Bon-pos likewise began to discover their "hidden" literature, and the texts they produced were, needless to say, permeated by the same type of teachings. The founder of Sakya (Sa-skya) monastery (founded 1073), after which the Sakyapa (Sa-skya-pa) order is named, was simply a Nyingmapa who wished to establish sound doctrine. During the historical vicissitudes of the next two centuries, his successors, who were certainly learned, became the religious masters of the great Mongol khans, from whom they received in return the mandate of political power throughout the whole of Tibet. (This political power was not held unchallenged; it endured about a century and even then the country remained more or less divided in allegiance to powerful monasteries and rival clans.)

Another important order, the Kagyurpa (bKa'-rgyud-pa; "Order of the Transmitted Word"), was founded by the translator Marpa, who had acquired his initiations and doctrines from the

Indian tantric yogin Naropa. Marpa was a householder; his chief disciple, Milaraspa, the most renowned of Tibetan sages, was a solitary hermit. This line developed into a large number of subsects, all monastic in type.

Another order, generally reforming in intention, was associated with Atisha or rather with his disciple 'Brom-ston, who founded Rva-sgreng monastery to the northeast of Lhasa. His order, known as the Kadampa (bKa'-gdams-pa; "Precept Giving") was absorbed in the 15th century by the last and now the most powerful of Tibetan religious orders, the Gelugpa (dGe-lugs-pa; "the Virtuous"), the order of the dalai lama and the panchen lama.

This last order was founded by an east Tibetan, Tson-k'a-pa (Tsongkhapa; c. 1358–1419), a scholarly writer and skilful preacher, who was intent on establishing monastic celibacy as the only legitimate form of religious life. He established a following in Lhasa, where he founded Ganden (dGa'-ldan) monastery. His immediate disciples founded two other monasteries, Drepung ('Bras-spun) and Sera, also on the outskirts of Lhasa. These subsequently became the main Gelugpa strongholds, dominating the capital with a joint total of about 20,000 monks. (The nickname "Yellow Hats" for the Gelugpa, commonly used by westerners, is possibly of Chinese origin. The corresponding nickname "Red Hats," as applied to all the other older orders, is a mistaken usage of foreigners, for it applies properly to only one subsect.) One of the most energetic organizers of the new order was dGe-'dun-grub-pa (Gentun Drupa; 1391–1474), abbot of Drepung, who was retrospectively recognized as the first rGyal-ba Rin-po-c'e ("precious conqueror"), the title by which Tibetans refer to the dalai lama.

The two foremost disciples of Tson-k'a-pa, namely rGyal-ts'ab-rje and mK'as-grub-rje (Khedru), acted as abbots of Tson-k'a-pa's own monastery, Ganden, and when mK'as-grub-rje died in 1438 dGe-'dun-grub-pa seems already to have resolved to find as his successor a boy born in the same year. Precedents for this practice can be traced back to the 13th century at least. The idea of a divine being manifest as a human teacher was already established in Indian Buddhism, and the theory of rebirth is of course fundamental to Buddhism in all its forms. It was by combining these ideas and claiming the ability to recognize one after another the representatives of such a series that the Tibetans devised a unique system of heredity. dGe-'dun-grub-pa died at the monastery of Trashi Lhümpo (bKra'-sis-lhun-po), which he had built (1447–52) in honour of his departed master, and a worthy successor was found as abbot. It was only later that his "reincarnation" was discovered. Thereafter, however, the system of reincarnations was accepted as the general rule. Drepung became the seat of the "precious conquerors," and Trashi Lhümpo that of the "precious sages" (Pañ-c'en Rin-po-c'e, the panchen lama). Political power over the whole of Tibet came to the fifth "precious conqueror" by the arms of the Mongols, who had been reconverted to Buddhism by his great predecessor, the third.

All the different orders have developed their own literary traditions, biographical, historical, doctrinal and liturgical, and thus the scope of Tibetan literature is now enormous.

**Religious Theory and Practice.**—In general, Tibetan religion represents the developed Mahayana Buddhism of India, which includes tantric theory and practice, known either as Vajrayana ("vehicle of mystic power"; literally "thunderbolt") or Mantrayana ("vehicle of mystic spells"), together with indigenous Bon notions which were easily adaptable. Thus the Bon idea of divine kingship finds a new Buddhist form in the theory of reincarnating lamas; the old priests of Bon now have Buddhist oracular soothsayers as their counterparts; the old local gods are now conceived of as serving the new religion and receive sacrificial offerings as a kind of fee for their continuing good will; the offerings consist of conventional sacrificial cakes, and the "flesh-offerings" prepared for bloodthirsty divinities are simply specially prepared cakes made to look sufficiently gruesome. Religious practice proper (study of religious texts, meditation, self-discipline and the practice of morality) is entirely Buddhist in character, and its efficacy as a way of perfection (in terms of the Buddhist ideal of blissful equanimity pervaded by loving kindness) is proved by the un-

doubted existence of a minority of very deeply religious men, as well as by the far greater number whose well-balanced personalities manifest the results of such a training. This is not to claim that Tibetans are always more virtuous than other peoples, though they are probably more morally conscious. Their religious susceptibilities are certainly highly developed, ranging from fervent and well-directed faith to vague superstition. Since 1950, however, when the Chinese communists invaded the country, Tibetan religion and culture have been put to a severe test; thus their future is dark and uncertain.

**TIBETAN LANGUAGE.** Tibetan belongs to the Tibeto-Burman group of languages and is now basically monosyllabic. Estimates of the number of people who speak its various dialects are divergent: 3,000,000, including those in China, Nepal, and other Himalayan states, as well as Tibet, being a possible approximation. Within Tibet, dialects spoken comprise Central (*dbus-skad*), Tsang (*gtsan-skad*), Western (*stod-skad*), Nomad dialects (*'brog-pa'i skad*) both western and eastern, and the dialects of Kham, Amdo, and Gyarong (rGyarung) in the east. Outside Tibet, dialects spoken, e.g., in northern Nepal, include Sherpa, Mustang, and Dolpo. Because of the political importance of Tibet's capital and sacred city, Lhasa, Central Tibetan may be regarded as standard; but, under the influence of Lhasa society, it has been elaborated with a duplicated vocabulary consisting of ordinary terms for familiar speech and honorifics for polite discourse, so that it is particularly difficult not only for foreigners but also for other Tibetan speakers.

For all the dialects there is a single written form (see TIBETAN LITERATURE), characterized by a complex system of silent prefixes and suffixes serving to distinguish verbal forms as well as words of similar pronunciation; and variable particles corresponding to European case-endings and conjunctions. Words of two or more syllables can normally be split into meaningful monosyllables. The dialects of the outer regions bear a slightly closer relationship to the stylized literary spellings than do the inner dialects.

Study of Tibetan as a member of the Sino-Tibetan language division has yielded relationships between Tibetan words and those of reconstructed ancient Chinese.

(D. L. SN.)

**TIBETAN LITERATURE.** Tibetan was developed as a literary language from the 7th century onward as a result of earlier cultural contacts with neighbouring Buddhist countries, namely, the small states of the Takla Makan, especially Khotan (Ho-t'ien), and the ancient kingdoms of northwestern India (modern Gilgit, Kashmir and Kulu) and Nepal. Scripts of Indian origin were in use in these countries, so the Tibetans also adapted an Indian script to suit their own very different language. By far the greater number of the works produced between the 7th and the 13th centuries are skilfully methodical translations of Buddhist works, largely from Sanskrit, on which Indian scholars and Tibetan translators worked side by side. In order to translate them the Tibetans had to create an entirely new (and therefore artificial) vocabulary of religious and philosophical terms, mainly by ingenious compounding of simple terms available in their own language. Apart from some religious terms in daily use, this vocabulary remains a specialized scholarly language. An indigenous literature was also produced: annals and chronicles, sets of spells and prognostications, legendary and liturgical works, all representing the remains

of ancient oral traditions. Large collections of such manuscript fragments, all earlier than the 11th century, were discovered early in the 20th century in the caves of Tun-huang (at the eastern side of the Takla Makan).

The quasi-official work of translating authorized Indian Buddhist texts, which continued for six centuries, gave incentive to the Bon-pos (the followers of the pre-Buddhist religion of Tibet) to collect and write down their own early traditions, but in so doing they adopted many Buddhist ideas and, inevitably, used the new vocabulary. The followers of the earliest Buddhist traditions to enter Tibet (the rNin-ma-pa or "Old Order") also committed their teachings to writing, and, conversely, these are interspersed with pre-Buddhist traditions.

The official Tibetan Buddhist canon was closed in the 13th century; it consists of two parts, the *Kanjur* ("translated word," teachings or reputed teachings of the Buddhas themselves) and the *Tenjur* ("translated treatises," mainly commentaries by Indian teachers). By this time, however, there already existed some orthodox Buddhist works of Tibetan origin (e.g., *Mila-raspa* and *sGam-po-pa*; see *Bibliography*) and from the 13th century onward, under the impetus given by the prolixity of religious houses and orders, there were produced such lengthy and numerous collections of historical and biographical works, treatises and commentaries, liturgy and religious drama that Tibetan literature must be one of the most extensive in the world. Just as in the European middle ages there was little secular literature worth the name, so there is none in Tibetan except for the great epic which recounts the exploits of the king and magic hero, Gesar. This work has grown through the centuries, assimilating whatever material has pleased the fancy of the bards.

After the craft of printing from incised wood blocks (xylography) was introduced from China, probably in the 10th century (see PRINTING), certain monasteries became famous printing houses. This form of printing continued until the Chinese invasion in 1959. Manuscripts and block-printed books are always of elongated shape, thus imitating the form of ancient Indian palm-leaf manuscripts. There are considerable collections in some European libraries—notably those of London, Paris and Rome—but few translations are available, because of the paucity of Tibetan scholars.

Despite the phonetic changes in the spoken dialects since the script was fixed, the Tibetans have never changed their system of writing. Thus, once the literary language and the various types of script have been mastered, the reader has immediate access to all the literature of the 7th to the 20th centuries, although changes in style and vocabulary have left many obscurities in the earliest works. There is no modern style of writing, so that the 20th-century colloquial language can only be written in the traditional medium (as though, for example, one had to write modern Italian with Latin spellings and grammatical forms); the Tibetans themselves compose even personal letters in a conventional literary style.

family which did not belong in the Chinese or Tai branches were considered to belong to a Tibeto-Burman subfamily. Through the work of the Norwegian scholar Sten Konow with Sir George Grierson for the *Linguistic Survey of India* (see GRIERSON, SIR GEORGE ABRAHAM), sample vocabularies and texts were gathered from about 113 languages and 82 dialects, all of which showed similarities in phonology, vocabulary, and grammar. These were then classified as members of a Tibeto-Burman subfamily in the Sino-Tibetan or Indo-Chinese family.

Yet, when it was considered that hundreds of millions of people spoke a total of less than several dozen Chinese, Tai, and Miao-Yao languages it seemed incredible that about 40,000,000 people could speak more than 200 mutually unintelligible languages of the Tibeto-Burman subfamily. But, since the publication of linguistic data on more than 300 different Sino-Tibetan languages, it has become clear that there is indeed more linguistic diversity in the area covered by speakers of Tibeto-Burman languages than in any other comparable area or group of related languages.

All the languages formerly classified as Tibeto-Burman tend to show more agreement among themselves than do other Sino-Tibetan languages. However, scholars now consider Sino-Tibetan to be a linguistic phylum or macro-family (i.e., a major division of

languages whose member families have a common ancestral language which may or may not be reconstructible) consisting of nine more or less coordinate language families; i.e., Chinese, Miao-Yao, Kam-Tai, Karen, Burmese-Lolo, Tibetan, rGyarung-Mishmi, Bodo-Tangsa-Kachin, and Naga-Chin. The validity of the Tibeto-Burman subfamily hypothesis is likely to remain questionable for many years; but the term is still useful to cover those Sino-Tibetan families which contrast with the Chinese, Miao-Yao, and Kam-Tai. Most of them are spoken in isolated and mountainous areas, for which population figures are generally unavailable or inaccurate.

**Tibeto-Burman Families.**—The largest of the Tibeto-Burman language families is Burmese-Lolo, spoken by the Hani in Tongking and Laos; by the Lisu (q.v.), Labu, and Akha (see KAW) in Thailand; and by approximately two-thirds of Burma's population. From Yunnan north into western Szechwan two small groups extend, the Ch'iang and the Sifan, speaking quite divergent languages. In ancient days the Sihia (Sihia) language, now extinct, was also spoken in this area; it is the only ancient Tibeto-Burman language of which written records provide a clue to its phonetic system. In north Yunnan are the Na-khi (Nashi or Moso) and Nosu (or Lolo, see Yi), founders of ancient kingdoms who later also played important roles in the Nanchao kingdom of central Yunnan in the 7th-8th centuries (see BURMA: History). The Lolo tribes extend eastward into Szechwan and Kweichow.

Dialects of Tibetan are spoken by an estimated aggregate of about 3,000,000 in Tibet, China (Tsinghai, Kansu, Szechwan, and Yunnan), and Himalayan border states. These last are divided into several distinct branches on the basis of the occurrence of pronominal affixes with the verb. (See TIBETAN LANGUAGE.)

The rGyarung-Mishmi family has three widely separated branches. On the Assam-Tibet border various Mishmi languages are spoken. In eastern Tibet rGyarung, long considered merely a divergent dialect of Tibetan, has now been recognized as a separate language. The Nung-Rawang group in the centre, where India, Tibet, Burma, and China meet, and formerly thought to be Kachin dialects, have proved to contain a number of separate languages.

Another family of Tibeto-Burman has been given the cover term Bodo-Tangsa-Kachin from its major language branches. Bodo languages are spoken on a line from Bhutan southward to Tripura state adjoining East Pakistan. Kachin languages are spoken from western Yunnan throughout north Burma into the North East Frontier Agency (N.E.F.A.) area of Assam. In between are related Tangsa languages formerly classed with the Naga (q.v.).

To the southeast of these the Naga-Chin family covers languages from the ancient Meithei (q.v.), Sak, and Kuki to the dozens of Naga and Chin languages spoken from Assam southward to the Arakan mountains of Burma. The Karen languages, long considered a separate family, and found throughout southern Burma and northern Thailand, are now classed with the other Tibeto-Burman languages.

In early times only Tibetan, Burmese, Lolo and Na-khi had written scripts. Tibetan and Burmese are alphabetic and based on the Indian Devanagari; ancient Nosu and Na-khi are hieroglyphic, and limited to use by the old Bon shamans. The 20th century has seen the development of literature in these and dozens more languages, in adaptations of the scripts predominant in their areas, and of the Roman alphabet.

**General Characteristics.**—Tibeto-Burman languages tend to exhibit the following characteristics:

1. Tonal contrasts, as an integral component of the phonetic syllable (except in Balti and Purik), vary from the simple two-level systems of Tibetan and Burmese to complex 3-4 level systems. Additional tonal contours may make as many as six contrasting tones, as in the Lolo (Yi) languages Lisu (q.v.) and Maru.
2. A much lesser degree of monosyllabism and isolating structure is seen than in other Sino-Tibetan families; most of the languages are agglutinative, with varying degrees of inflection usually expressed by affixes and leaving the root unchanged.
3. Pronominal agreement expressed within the verb affixal structure, though not found regularly as a trait of Tibeto-Burman, nevertheless occurs in three of the families: Tibetan, rGyarung-Mishmi, and Naga-Chin.

4. In the characteristic word order, modifying words, phrases, and clauses precede the primary or head word (noun or verb), with affixal particles following. Inflectional affixes with verb forms usually include categories of voice, direction, aspect, and mode.

**TIBULLUS, ALBIUS** (d. c. 19 B.C.), Roman poet, the second in the classical sequence of Latin writers of elegiacs that begins with Cornelius Gallus and continues through Tibullus and Propertius to Ovid. Apart from his own poems, the only sources for the biography of Tibullus are a few references in ancient writers and an extremely short *Life* of doubtful authority. He was of equestrian rank (according to the *Life*) and inherited an estate, but seems to have lost most of it in 41 B.C. when Mark Antony and Octavian confiscated land for their soldiers (Virgil, Propertius and Horace suffered in the same way). As a young man, however, Tibullus won the friendship and patronage of M. Valerius Messalla Corvinus, the statesman, soldier and man of letters. Despite personal reasons for staying at home, he would even have accompanied Messalla on a mission to the east if sickness had not obliged him to remain behind when the party left Corcyra, and it is sometimes alleged that he accompanied Messalla's expedition against the Aquitanians. In any case, Tibullus was a prominent member of Messalla's literary circle. This circle, unlike that of Maecenas, kept itself aloof from the court of Augustus, whom Tibullus does not even mention in his poems. Tibullus seems to have divided his time between Rome and his country estate, strongly preferring the latter. The Albius addressed by Horace in *Odes*, i, 33, and *Epistles*, i, 4, is generally identified with Tibullus.

Tibullus' first important love affair, the main subject of book i of his poems, was with the woman whom he calls Delia but whose real name, according to Apuleius, was Plania. It is impossible to give an exact account of their intimacy, as the poems about her are not arranged in chronological order: sometimes he presents her as unmarried, sometimes as having a husband (unless the term *conjux* is to be interpreted as meaning merely "protector"). It is clear, however, that Tibullus took advantage of the "husband's" absence on military service in Cilicia to establish his relationship with Delia and that this relationship was carried on clandestinely after the soldier's return until Tibullus discovered that Delia was receiving other lovers as well as himself; then, after fruitless protests, he ceased to address himself to her. In book ii of his poems Delia's place is taken by Nemesis (also a fictitious name). This Nemesis was a courtesan of the higher class, with several lovers. Though he complains bitterly of her rapacity and hardheartedness, Tibullus seems to have remained subjugated to her for the rest of his life. He died young, very shortly after Virgil (19 B.C.), as is proved by an epigram of his contemporary, Domitius Marsus. Ovid commemorated his death in his *Amores* (iii, 9).

**Character and Style.**—The character of Tibullus, as reflected in his poems, is an amiable one. He was a man of generous impulses and a gentle unselfish disposition. His loyalty to his friends is shown by his leaving Delia to accompany Messalla to Asia, and he was constant to his mistresses with a constancy that they scarcely deserved. His tenderness toward women is enhanced by a refinement and delicacy which are rare among the ancients.

Horace and the rest taunt those who reject their claims with the damage that the years will do to their beauty, but if Tibullus refers to old age, he does it by way of warning, not in a spirit of triumph or revenge. Cruelly though he may have been treated by his love, he does not invoke curses upon her. Instead he goes

to her little sister's grave, hung so often with his garlands and wet with his tears, and bemoans his fate there. Tibullus has no leanings to an active life: his ideal is a quiet retirement in the country with the loved one at his side. He has no ambition and no yearning for immortality. As he loved country life, so he clung to its faiths, and in an age of crude materialism and strange new cults he was religious in the old Roman way.

The poetry of Tibullus is distinguished by an idyllic simplicity, but this is the simplicity of high art, not of unadorned nature. For grace and tenderness, for exquisiteness of feeling and expression, he stands alone among the Roman elegists: Quintilian, indeed, puts him at their head. In many of his poems, moreover, a symmetry of composition can be discerned, though they are never forced into any fixed or inelastic scheme. His clear and unaffected style, which made him a great favourite with Roman readers, is far more polished than that of his rival Propertius and far less loaded with Alexandrian learning; but in range of imagination, in power and originality of conception, in richness and variety of poetical treatment Propertius is much superior to him. In his handling of metre, likewise, Tibullus is smooth and musical, whereas Propertius, with occasional harshness, is vigorous and varied.

**"Corpus Tibullianum."**—The works of Tibullus, as they have survived, form part of what is generally known as the *Corpus Tibullianum*, a collection of poetry which seems most probably to have been deliberately put together to represent the work of Messalla's circle; when and by whom this was done must in the present state of the evidence remain obscure.

The first two books of the collection are the undoubted property of Tibullus. Book i contains the poems inspired by Delia and also three elegies (4, 8 and 9) addressed to Marathus, a beautiful boy. These three elegies may reflect a literary convention, not the poet's actual feelings, as many of the sentiments throughout the book are those expected of the professed elegist: for instance, Tibullus' alleged poverty (i, 1) is at variance with the facts if he is the Albius addressed by Horace. The most interesting of the Marathus poems is that (4) in which the god Priapus is made to deliver a brief sketch of the art of love, the prototype of Ovid's fuller treatment of the same theme in the *Ars amatoria*.

Book ii is by no means entirely devoted to the liaison with Nemesis: it contains one of Tibullus's most characteristic and delightful poems, the description of a country festival (1).

The rest of the *Corpus Tibullianum* forms one book in the manuscripts; the division into two books, iii and iv, in modern editions is due to Italian scholars of the 15th century. Book iii contains six poems, the work of a poet who styles himself Lygdamus, an obvious pseudonym. They celebrate a lady named Neaera and are cultivated but on the whole undistinguished compositions. The writer's identity has been much debated, but remains unknown. If the *Corpus* does indeed represent the poets associated with Messalla, this Lygdamus should have been a contemporary of Tibullus and Ovid; and one couplet (5, 17-18) seems to indicate that his birthday was the same as Ovid's. This, together with the striking verbal resemblances which are found in his poems, has led some to identify him with Ovid; but neither this nor any other of the proposed identifications (with Ovid's brother, with Propertius, with Tibullus himself) will stand scrutiny. (It seems certain, however, that the resemblances between the two poets are due to Lygdamus' having copied Ovid, not vice versa.)

The first poem of book iv, a panegyric on Messalla, is a turgid and worthless composition. The next 11 poems were occasioned by the love of Sulpicia for a young man called Cerinthus: poems 7-12 are Sulpicia's; 2-6 are usually thought to be by Tibullus. The whole cycle forms a unique and charming document for the literary life of Augustan Rome. The last poems (13 and 14), addressing an unnamed love, are likewise generally attributed to Tibullus.

The best texts are in the editions by J. P. Postgate, 2nd ed. (1915) and by F. W. Lenz (1959); that by K. F. Smith has an excellent introduction and commentary (1913). There are English translations by J. P. Postgate, in prose, with Catullus, in the Loeb series (1913), and by A. S. Way, in verse (1936).

Lee, article in *Proceedings of the Cambridge Philological Society*, no. 185 (1958–59). (J. P. P.; E. J. K.v.)

**TIC** (from a French word *tique*, meaning "a twitching") is a sudden, rapid, recurring contraction in a muscle or group of muscles. The movement is always brief, irresistible, and limited to one part of the body. It does not interfere with the use of the part involved, and may be halted voluntarily but only for a time. As the tic movement becomes ingrained it is looked upon as a habit; the possessor becomes relatively unaware of its occurrence. Then a tic may be considered as involuntary. These characteristics of tic help to differentiate it from other involuntary movements, such as spasm (see **CRAMP**) or the capricious, uninhabitable movements that may occur in chorea (*q.v.*; St. Vitus' dance) or in epilepsy (*q.v.*). Tics are not mannerisms.

While very nearly all tics are of psychological origin, similar repetitive movements have been observed in the late stages of encephalitis (*q.v.*). These movements that accompany brain disease may persist for years, but they tend to cease eventually.

Nervous children between 5 and 12 years of age are those most likely to have tics, but no age is immune. The movement appears when the subject is tense, and distraction will reduce it. The sufferer knows that he has a certain control of the movement but feels impelled to go through with it in order to feel better. Sometimes a group of tics occur in rapid succession, and the condition is then termed convulsive tic.

Tics frequently involve the face and air passages. The commonest tics are a repetitive grimace, blink, sniff, snort, or click in the nose or throat, a twitch, or a shrug. Tics occur in decreasing frequency from head to foot.

**Psychological Analysis.**—Tics are the involuntary motor expression of emotional activity, and they depend primarily upon the manner in which the tiqueur (the medical term for a person subject to tics) has experienced his early psychological and sexual development. Compulsion neurosis is common among tiqueurs (see **NEUROSES**). Compulsive neurotics are in conflict about certain of their feelings; they suffer from the irresistible impulse to perform some act contrary to the conscious will. The need to "get rid of" something is implicit in tic activity.

The use of the muscles for immediate discharge indicates intolerance of tension and inability to wait; the tiqueur feels impelled to make the movement in order to feel better. The tension is thereby discharged; in other words the person temporarily relieves himself—of what, he does not know. Such inability to wait is characteristic of the activity of children who have to learn how to accept delay of their gratifications and to channel their energies into socially acceptable activity. Should they continue this kind of intolerance into adulthood, the nervous patterns may gradually narrow their target to become a tic as the movement becomes more automatic than willed.

The muscles are among the main avenues used by infants in the expression of the emotions, such expression appearing before that of speech in the developing child. It follows that primitive emotion relatively untempered by learning, or vulnerable because of bodily disease, may show itself by way of the muscular system. Somewhat later in development the musculature may be used to repress or restrain certain emotional expression. In persons with tic it can be determined that the usual outlets for expression of the emotions were denied in childhood: restriction of motility has resulted in an increased motor urge; overprotection, usually based on the mother's fear, has made the child emotionally dependent and lacking in self-control. Tics thus may be accompanied by other indications of maladjustment, such as bedwetting, feeding and digestive disorders, and exaggerated fears.

The older tic personality may respond to psychotherapy devised

to mature the subject (learning why he behaves the way he does), who has usually retreated—in a defensive maneuver—to an earlier stage of psychological development where he feels more secure.

Usually there are features of both the compulsion neurosis and hysteria in tiqueurs. In hysteria (*q.v.*) repressed sexual energy is converted into symptoms. Where there is the capacity for relationship, prolonged uncovering psychotherapy may be helpful. (C. D. AR.)

**TICHBORNE CLAIMANT**, the name given to a man who claimed to be Roger Charles Tichborne, heir to the Tichborne baronetcy and estates in Hampshire, but who was declared by a jury in 1874 to be Arthur Orton, the son of a butcher of Wapping, London. Roger Charles Tichborne (1829–54 or 1898) was born in Paris, the eldest son of James Francis Tichborne (1784–1862), who in 1853 became 10th bart. and took the surname of Doughty-Tichborne, and Henriette Felicité (d. 1868), illegitimate daughter of Henry Seymour of Knoyle, Wiltshire. He sailed in March 1853 from Le Havre for Valparaíso, Chile, and later crossed the Andes, reaching Rio de Janeiro, Brazil, in 1854. In April 1854 he sailed from Rio in the "Bella" and the ship was lost at sea with no known survivors. His insurance was paid and his will proved in July 1855.

On his father's death in 1862 Roger's younger brother Alfred Joseph (1839–66) succeeded as 11th bart. Roger's mother, the dowager Lady Tichborne, refused to believe that her son was dead and from 1863 advertised widely in newspapers asking for news of him. In November 1865 she learned through a missing persons agency in Sydney, Austr., that a man claiming to be her son was working as a butcher in Wagga Wagga, New South Wales, under the name of Thomas Castro. In January 1867 the claimant reached Paris where he was "acknowledged" by Lady Tichborne.

Other members of the Tichborne family, however, asserted that he was an impostor and obtained evidence to try and prove that he was Arthur Orton (1834–98 or ?), who had deserted his ship at Valparaíso in 1849. They alleged that Orton had been kindly received at Melipilla, Chile, by a family called Castro, whose name he took after he had gone to Australia in 1854. The claimant, however, also declared he had stayed with the family at Melipilla during his visit to Chile in 1853. An ejectment action brought by the claimant against the trustees of the Tichborne estate (Sir Henry Alfred Joseph [1866–1910], 12th bart., being then a minor) finally came before the Court of Common Pleas on May 11, 1871. During the trial more than 100 persons swore that he was Roger Tichborne, but the evidence brought by the family finally convinced the jury, who on March 6, 1872, declared that they wanted no further evidence.

Arrested on a charge of perjury, the claimant was brought for trial at the bar on April 23, 1873, before Chief Justice Sir Alexander Cockburn. The mismanagement of the case by his counsel, Edward Kenealy, the testimony of Orton's former sweetheart Mary Ann Loder, and Kenealy's refusal to put Orton's sisters into the witness box finally proved conclusive to the jury, who on Feb. 28, 1874, the 188th day of the trial, found that the claimant was Arthur Orton. Found guilty of perjury, the claimant was sentenced to 14 years' penal servitude. Released in October 1884, he died in poverty in Marylebone, London, on April 1, 1898.

See D. Woodruff, *The Tichborne Claimant* (1957).

**TICINO**, a wedge-shaped Swiss canton, driven into Italy. Its northern boundary runs along the Lepontine-Adula Alps, and its southern tip reaches beyond Lago di Lugano almost to Como. Historically, it represents early Swiss conquests from the duchy of Milan (see **SWITZERLAND: History**) loosely amalgamated to form one of the six cantons admitted to the Confederation in 1803. It is inhabited by Italian-speaking Catholics (see below). Its dominant physical features are the three river systems occupying steep-sided valleys which extend from a mountain frontier and drain southwards to Lago Maggiore. The most important system is the river Ticino, which rises in the canton southwest of St. Gotthard, flows towards that mass through the Val Bedretto, and then swings round at Airolo to a southeast course through Valle Leventina; near Biasca it receives the left-bank Brenno from the Val Blenio; the combined stream flows through the wide,

low valley—the Riviera—until slightly above Bellinzona, where it receives another large left-bank affluent which has drained the southeast slopes of the Adula group and reaches the Ticino via the Valle Mesolcina; the main stream curves again below the junction and enters the lake from the east. The Ticino receives no important right-bank tributaries, and the western part of the canton is drained largely by the Maggia and by its numerous right-bank tributaries, which receive torrent water from the western frontier. Between the Ticino and the Maggia is the Valle Verzasca.

The remainder of the canton lies south-southeast of this and consists of a triangular fragment of broken hill country, with a complicated drainage reaching the irregularly shaped Lago di Lugano.

Its total area is 1,085 sq.mi., of which approximately three-quarters are reckoned as "productive" (forests covering about 275 sq.mi.), while of the remainder 28.6 sq.mi. consists of lakes, chiefly parts of Maggiore and Lugano; 13 sq.mi. are occupied by glaciers. The canton is fifth in point of size, but only the much larger Valais and Vaud exceed its vine-growing area. The highest points are the Basódino (10,738 ft.), near the western border, southeast of the source of the Ticino, and the Rheinwaldhorn (11,161 ft.) in the Adula Alps.

The amount of lowland is small, and occurs only in the lower river valleys and near the lakes. The lowest commune (669 ft.) is Vira (Locarno) on Lago Maggiore.

The main St. Gotthard railway traverses the canton for about 75 mi. from Airolo, at the southern mouth of the tunnel, via Valle Leventina, Bellinzona, Lugano to beyond Mendrisio. Locarno is connected with this line; another follows the eastern shore of Lago Maggiore, and light electric railways ascend Valle Blenio to Acquarossa and Valle Mesolcina to Mesocco. A bus service has replaced the former light railway of Valle Maggia to Bignasco. Mountain railways for the ascent of Monte S. Salvatore (2,992 ft.) and Monte Brè (3,061 ft.) from Lugano and of Monte Generoso (5,584 ft.) from Capolago, have also been constructed in the extreme south of the canton.

In 1960 the population was 195,566, of whom 172,521 were Italian-speaking, 18,498 German-speaking, and 2,839 French-speaking. The highest commune, Bosco-Gurin, near the western border and reached by the V. di Campo, had many German-speaking inhabitants, the result of an early movement eastward from Valais. There were in all 178,625 Catholics, 13,330 Protestants and 572 Jews.

In 1888 the diocese of Lugano (since joined to Basel) was created to replace the former purely Italian control over the canton by the dioceses of Milan and Como. Bellinzona (pop., [1960] 13,435) was the permanent political capital after 1881; formerly Lugano (pop., [1960] 19,758) and Locarno (pop., [1960] 10,155) alternated with it at six-year intervals. Mendrisio is the only other large settlement.

The canton has 253 communes and 8 administrative districts; its constitution dates back to 1830, but the later political disturbances which characterize the canton have caused, and still cause, considerable modifications. The legislature (*Gran consiglio*) is composed of 65 members elected (since 1892) in the proportion of one to every 1,500 of the Swiss inhabitants. The executive (*Consiglio di stato*) of five members, is elected directly by the people. Both bodies hold office for four years. Any 5,000 electors have the right (facultative referendum) of claiming a popular vote as to bills passed by the legislature, while the same number of electors have the right of "initiative" in legislative matters, though 7,000 signatures are required in case of a proposal to revise the cantonal constitution.

**History.**—The canton is made up of all the permanent conquests (with one or two trifling exceptions) made by different members of the Swiss confederation south of the main chain of the Alps.

From an historical point of view Italian Switzerland falls into three groups: (1) the Val Leventina conquered by Uri in 1440 (previously held from 1403 to 1422); (2) Bellinzona (previously held from 1419 to 1422); the Riviera and the Val Blenio, all

won in 1500 from the duke of Milan by men from Uri, Schwyz and Nidwalden, and confirmed by Louis XII of France in 1503; (3) Locarno, Val Maggia, Lugano and Mendrisio, seized in 1512 by the Confederates when fighting for the Holy League against France, ruled by the 12 members then in the league, and confirmed by Francis I in the treaty of 1516. These districts were governed by bailiffs holding office two years and purchasing it from the members of the league; each member of group 3 sent annually an envoy, who conjointly constituted the supreme appeal in all matters.

This government was very harsh and is one of the darkest pages in Swiss history. Yet only one open revolt is recorded—that of the Val Leventina against Uri in 1755. In 1803 all these districts were formed into one canton—Ticino—which became a full member of the Swiss confederation. After 1830 the local history of the canton was disturbed by friction between the Radical and Ultramontane parties.

**Resources and Industries.**—Ticino has no minerals; it possesses, however, large supplies of water power (white coal) for internal use and export. Grazing is of considerable importance in the valleys of the upper part of the canton (Sopraceneri). Grapes are grown in the warmer south and good wine is produced in large quantity; wheat, potatoes, tobacco and vegetables are also grown for internal use. Owing to a favourable climate, especially on the shores of Lago Maggiore and Lago di Lugano, tourism has become the most important source of profit for the inhabitants.

**TICINO RIVER** (ancient *TICINUS*), the source of which is in the Swiss Alps near Passo di Novena, 7,500 ft. (2,300 m.) above sea level, drains an area of 2,800 sq.mi. (7,200 sq.km.), much of which is in Italy. The river is 154 mi. (248 km.) long, flowing southeast in the Val Leventina, which is followed by road and rail from St. Gotthard Pass, to Bellinzona, then west into Lake Maggiore, where it is joined by the Toce. It then flows southeast in a floodplain 1–2 mi. wide and 30–50 ft. below the surrounding North Italian lowland into the Po River 4 mi. (6 km.) southeast of Pavia. The river is fullest in May and November, lowest in September and late winter. The Ticino and its tributaries in the Canton Ticino above Lake Maggiore are an important source of hydroelectric power for Switzerland, while the Toce and its tributaries likewise serve Italy. The Ticino is not suitable for navigation. The two principal towns on the river are Bellinzona and Pavia. (J. P. Co.)

**TICK**, a spider relative externally parasitic on terrestrial vertebrates. Ticks along with mites constitute a taxonomic group given by various authors as a subclass or an order of the class Arachnida (*q.v.*). They are among the most important parasites of large wild and domestic animals in both economic loss and transmission of disease. While no species of tick is primarily a human parasite, some species do attack man when the opportunity presents itself. (For certain wingless ectoparasitic flies, such as the sheep ked, often popularly called ticks, see *FLY: Disputed Groups*.) Ticks may be grouped in the suborder Ixodides, which may be divided into three families (see *MITES* for a different taxonomic interpretation): Ixodidae (hard-backed ticks), Argasidae (soft-backed ticks), and Nuttalliellidae (represented by a single rare African species). Larger than mites, the largest ticks are up to 30 mm. long (more than one inch); most are less than half that length. Ticks can be distinguished from mites by their lack of body segmentation and by the presence of a sensory pit (Haller's organ) on the terminal segment of the first pair of legs.

Hard-ticks like the American dog tick (*Dermacentor variabilis*) attach to their hosts and feed continuously for several days. When engorgement is complete, the female drops from the host, finds a suitable site where she rests, lays her eggs in a mass, and dies. Six-legged larvae hatch from the eggs, move up on blades of grass, and lie in wait for a suitable host to pass by. When they contact a suitable host (usually a small mammal) they attach to it, obtain a blood meal, and detach. After a time the detached larva molts to become an eight-legged nymph. Nymphs again play the waiting game. After engorgement, they drop off, and molt into adult males or females. Again the adults wait for a host (adult ticks have been known to live for three years without food or

drink), and the cycle is repeated. Most of the hard-ticks carry on their developmental cycles in fields and woods, but a few, like the brown dog tick (*Rhipicephalus sanguineus*), are household pests. Soft-ticks are similar to hard-ticks in many respects, but differ in that they feed intermittently, lay several batches of eggs, pass through several nymphal stages, and carry on their developmental cycles in the home or nest of their host rather than in the field. Soft-ticks like the fowl tick (*Argas persicus*) are found most frequently on animals that have regular roosts or nests, such as bats and birds. They infest chicken houses and, in dry countries where sanitation is primitive, human habitations.

Hard-ticks damage their hosts by drawing excessive amounts of blood, by secreting neurotoxins under some conditions that produce paralysis and death, and by transmitting disease. Hard-ticks are the vectors of Texas cattle fever, anaplasmosis, Rocky Mountain spotted fever, Q fever, tularemia, hemorrhagic fever, encephalitis, and other diseases of man and animals (see RICKETTSIAE). Soft-ticks are important vectors of spirochetal relapsing fever (see RELAPSING FEVER) and other diseases.

Hard-ticks can be controlled on livestock by dipping or spraying the herds with suitable acaricides and by quarantine of infested animals. Man can best avoid ticks by impregnating his clothing with a tick repellent when exposing himself in infested areas. Elimination of soft-ticks from hen houses and the brown dog tick from homes can be accomplished by repeated treatment of the premises with an approved acaricide.

See also references under "Tick" in the Index. (G. W. W.)

See D. R. Arthur, *Ticks and Disease* (1962).

**TIDAL POWER.** The idea of utilizing the rise and fall of the tides to produce power has long attracted the attention of inventors, and many ingenious schemes have been suggested. So far, however, the only practicable method is based on the use of one or more tidal basins, separated from the sea by dams or barrages, and of hydraulic turbines through which the water is passed on its way between the basin and sea or between two basins.

**Early Uses.**—The earliest use of tidal water as a source of power was by means of a tide mill, a kind of water mill. Some depended on the tide alone, others used a proportion of fresh water. A storage pond was formed by enclosing part of a creek or estuary or by damming a tidal stream at its entrance to an estuary. Automatic lock-type gates or flap valves were set in the wall or dam, enabling the tide to fill the pond as it rose. When the tide fell, the water could be released through a sluice in order to drive a water wheel.

The Domesday Book mentions what seems to have been a tide mill at the entrance to the Port of Dover, Eng. This was built after 1066 and was a danger to vessels entering the harbour. The first mills of record were Three Mills, Bromley-by-Bow, London, in 1135 and that at Woodbridge, Suffolk (1170). In the Netherlands there was a mill at Zuiksee in 1220. Tide mills were built on sites around the coast of Great Britain, along the west coast of the European continent from the Netherlands to the south of Spain, along the eastern seaboard of colonial America, and on the coast of Surinam. The first tide mill in colonial America was built at Salem in 1635. In Surinam tide mills operated from 1667 to 1860. (R. W.)

**Modern Designs.**—The best plan for a given site depends on its geographical features, the tidal flow, its potential power capacity, and its economic feasibility. Each length of barrage separating a tidal basin from the sea or from another tidal basin may consist of either sluices or turbine-generators that can also act as motor-pump units—that is, if there is a sufficient head of water to drive the turbines, the generator will produce electric power; if not, electric power from an outside source can be used to drive the generators as motors, and the turbines then operate as pumps to move water from sea to basin or vice versa.

A tidal power plant constructed according to a well-defined plan may be operated in an almost unlimited number of ways. Below are three simple examples of working cycles:

**Production of Energy During Emptying or During Filling.**—During emptying, the sluices fill the basin while the tide is coming in and are closed at high tide. Emptying does not begin until

ADAPTED FROM "POPULAR MECHANICS," JUNE 1964

PLAN OF TIDAL POWER PLANT ON RANCE RIVER ESTUARY, SHOWING DAM AND ONE OF 24 REVERSIBLE TURBINE POWER UNITS

the ebb tide has left enough depth of fall to operate the turbines. This operation can be improved by using the energy available during the slack hours for pumping seawater in order to raise the basin level and increase the volume of water delivered to the turbines.

Conversely, energy may be produced during filling, when the turbines can be utilized to admit the incoming tide to the basin.

**Production of Energy by Utilizing Both Phases.**—The two preceding cycles may be combined, and energy can be produced while the basin fills and while it empties. However, the best results can be obtained by using the innumerable combinations of filling, emptying, and pumping according to the height of the tide and the value of energy at different periods of the day. Thus energy can be produced according to man's needs without the limitations imposed by depending on the lunar tidal rhythm alone.

**The Rance Plant.**—Construction was begun in January 1961 on the world's first large-scale tidal plant. This project, scheduled for completion by the end of 1967, is located on the Rance River estuary on the Gulf of St. Malo, Brittany, France. It was designed to comprise 24 hydroelectric power units of 10,000 kw. each and to average an annual net production of 544 Gw-hr. (gigawatt-hours)—537 Gw-hr. in the basin-to-sea direction and 71.5 Gw-hr. in the sea-to-basin direction, less 64.5 Gw-hr. of energy used in pumping.

After excavations on the estuary were completed in 1963, the flow into the Rance at spring tide attained a maximum of 635,670 cu.ft. per sec. (18,000 cu.m. per sec.) at both flood and ebb—about three times the amount of the flow of the Rhône at Avignon.

The 24 specially designed power units each consist of an ogive-shaped shell of metal containing an alternator and a Kaplan turbine. The units are installed in apertures in the dam through which the water flows, though a vertical shaft for maintenance gives access to the shell from the machine room above. Each unit acts as both turbine and pump, in both directions of tidal flow and both directions of rotation. A full-sized trial unit operating under conditions similar to those on the Rance successfully passed a five-year test by 1965.

**Other Projects.**—Tidal power plants have been proposed for the Bristol Channel in the United Kingdom, the Mezenskaya Gulf on the White Sea, the San José Gulf in Argentina, and at various points on the west Australian coast. The only serious plans under consideration in the latter 1960s were the U.S.-Canadian project for Passamaquoddy Bay and the French Chausey Bay project (several million kilowatts) to the north of St. Malo.

**BIBLIOGRAPHY.**—R. Gibrat, "Tidal Energy," *Civ. Engng. Publ. Wks. Rev.* (Feb. 1955); R. Gibrat and L. Kammerlocher, "Alternators for the Tidal Power Plant of the Rance," *Report No. 134, Conférence In-*

*Internationale des Grands Réseaux Électriques à Haute Tension* (May-June 1956). "Sources nouvelles d'énergie et de développement économique," U.N. publication No. E2997 (1957), lists 47 articles on tidal power. (R. Gr.)

**TIDE**, an alternating relative motion of the matter of a planet, satellite or star, which is attributed to the gravitational actions of external bodies. Such motions are known to occur in all three principal divisions of the earth. The alternating slight changes of shape of the solid body or lithosphere of the earth attributed to the gravitational action of the moon and sun are known as bodily tides. Similarly, there are the atmospheric tides in the atmosphere, and the familiar ordinary ocean tides in the hydrosphere. A still wider use of the word is based on descriptive instead of on causal and astronomical ideas, and takes for its criterion that the motions in question have certain features in common with ocean tides. This extension includes those long waves of the sea, or tsunamis, which are sometimes caused by earthquakes, as well as effects on the sea of variable atmospheric pressure and wind, known as meteorological tides.

### ORDINARY TIDES

**General Description of Phenomena.**—At most seaside places the water reaches its highest level approximately twice a day, the average interval between two successive high waters being 12 hr. 25 min., though this interval varies considerably during the course of a week. At certain places in the East Indian seas two successive high waters are separated by an interval of 12 hr., while at certain places in the China sea the interval is often more than 24 hr. At places on the shores of the oceans the time taken by the tide in rising is about equal to the time taken in falling on the same day, but in estuaries the tide usually rises more quickly than it falls. At certain places, such as Southampton, Eng., the high waters are often doubled; i.e., the water reaches a maximum height, falls a little and then rises to a maximum again. At other places the low waters are often doubled. As one goes along any stretch of coast the time of high water generally becomes progressively earlier or later, while as one goes up an estuary from the sea the time of high water always becomes progressively later.

At most places, on the average, a high water is about as much above the mean level of the sea as the succeeding low water is below it. The difference in level between successive high and low waters is called the range of tide. The range of tide at any place may vary much from day to day. At most places it reaches a maximum once a fortnight, and a minimum at times midway between two successive maxima. At London bridge the greatest range of the fortnight has an average value of 21 ft. while the least range of the fortnight has an average value of 15 ft. At the head of the Bay of Fundy the range of tide reaches 50 ft. while at certain islands of the Pacific and over most of the Mediterranean the range never exceeds 2 ft. At many places outside the Atlantic the heights of two successive high or low waters are markedly different, a phenomenon known as the diurnal inequality.

At a place in a strait or narrow sea the tidal current usually flows for about 6 hr. 12 min. in one direction, and then for about the same time in the opposite direction. At the reversal of such a current there is the state of rest usually called slack water. In estuaries the current generally flows downstream for a greater length of time than it flows upstream. At a place in the open sea the direction of the current often takes all points of the compass, making the complete revolution in the tidal period. During this period there are usually two times of maximum current and two intermediate times of minimum current. The times of maximum current are separated by about half the tidal period and the directions of maximum current are nearly directly opposite; similarly for the two minimum currents. There is no fixed general relation between the time of high water and the time of maximum current. If the current flows directly in and out of a bay it will reach its inward maximum nearly a quarter period before high water at the head of the bay, so that slack water is simultaneous with high water. On the other hand, in an estuary the current continues to flow upstream for some considerable time after high water and to run downstream similarly after low water. When the current is

directed toward land or up an estuary it is called the flood current; when it runs away from land or down an estuary it is called the ebb current. The speeds of tidal currents vary greatly from place to place; e.g., in the Seymour Narrows, British Columbia, the maximum current reaches ten knots; in the North sea it rarely exceeds one. At some distance up certain rivers—as, for example, where the Colorado river meets the tide—a wave ten or more feet high travels up the river almost like a wall of water. This phenomenon is called a bore. Near a headland separating two bays there is sometimes a swift current termed a race.

**Relation to Motions of Moon and Sun.**—The times of high water bear an intimate relation to the positions of the moon and sun. The period of 12 hr. 25 min. is half that of the moon's apparent revolution around the earth. The length of time between the moon's crossing of the meridian of a place and the next high water at that place is known as the lunitidal interval, or the high-water interval, for the place. Similarly, the length of time between the moon's crossing of the meridian and the next low water is called the low-water interval. For Philadelphia, the lunitidal average is 1 hr. 30 min. In many cases, including those of British waters, the chief variation in the lunitidal interval is associated with the phase of the moon. The average value of the lunitidal interval on the days of new and full moon is known as the establishment of the port. For London bridge this is 1 hr. 58 min.

The range of tide may be similarly correlated. In British waters it reaches its maximum a day or so after new and full moon and its minimum a day or so after the quarters. In these circumstances the maximum tides are known as spring tides and the minimum tides as neap tides. About the time of the equinoxes spring tides are generally larger and about the time of the solstices they are generally smaller than usual. The average interval between new or full moon and the next following spring tide is known as the age of the tide at the place in question. At certain places in Canadian waters the chief variation in the range of tide is associated with the varying distance of the moon from the earth, while at others it is associated with the varying declination of the moon. The diurnal inequality is always associated with the declination of the moon or sun. But the most complete correlation between the tides and astronomical variables is provided by the harmonic methods.

### HISTORY OF THE STUDY OF TIDES

The writings of various Chinese, Arabic and Icelandic authors show that they paid some attention to the tides, but the theories advanced are fantastic. The writings of the classical authors of antiquity contain but a few references to the tides, for the Greeks and Romans lived on the shores of an almost tideless sea.

Johannes Kepler in the early 17th century recognized the tendency of the water of the ocean to move toward the sun and moon, but Galileo's explanation referred the phenomenon to the rotation and orbital motions of the earth. It was Isaac Newton who, in his *Principia* of 1687, laid the foundation of the modern theory of the tides when he brought his generalization of universal gravitation to bear on the subject. He gave a geometrical construction for the tide-generating force, and calculated the magnitude of the solar equilibrium tide. He considered a canal encircling the earth and applied to each particle of water the laws which he had deduced for a satellite. He accounted for many of the general properties of the tides, such as the phenomenon of springs and neaps, priming and lagging, diurnal and elliptic inequalities. The only important factor which he did not mention is the dynamical effect of the earth's rotation. Newton's work was continued by D. Bernoulli, L. Euler and C. Maclaurin who adopted not only the theory of gravitation but also Newton's method of the superposition of two ellipsoids. In 1746 Jean le Rond d'Alembert wrote a paper on atmospheric tides, but this work, like Maclaurin's, is chiefly remarkable for the importance of collateral points.

The theory of the tidal movements of an ocean was almost untouched when in 1773 Pierre Laplace first undertook the subject. In his *Mécanique céleste* he formulated the equation of continuity and the dynamical equations, and applied them to the case of an ocean covering the whole earth. He also established the principle

of forced oscillations, which forms the foundation of the harmonic methods.

The connection between the tides and the movements of the moon and sun is so obvious that tidal predictions founded on empirical methods were regularly made and published long before mathematicians had devoted their attention to them. The best example of this kind of tide table was afforded by Moses Holden's tables for Liverpool, based on 20 years of personal observation by a harbour master named William Hutchinson. The use of automatic tide gauges appears to have begun about 1830.

The work of J. Lubbock, Sr. and W. Whewell is chiefly remarkable for the co-ordination and analysis of data at various ports, and for the construction of tide tables. Sir George Airy in his *Tides and Waves* of 1842 studied profoundly the theory of tidal motions in canals, while in 1848 and 1851 F. W. Beechey published the results of a survey of tidal currents over the Irish sea, the English channel and the North sea.

About 1863 W. Thomson (afterward Lord Kelvin) became interested in the problems presented by earth tides. In 1866 he took up the analysis of ordinary tidal observations and established the harmonic methods, which quickly developed. He introduced the rotation of the earth into the tidal dynamics of small seas, and in 1872 he designed a tide-predicting machine. His theory that the revolution of the earth's poles in a 16-ft. circle every 14 months caused small ocean tides was confirmed by computers in the 1950s.

In 1874 W. Ferrel, of the U.S. coast and geodetic survey, published his *Tidal Researches* which included a harmonic development of the generating potential, and from the same year A. W. Baird, of the survey of India, organized a service of observation and harmonic analysis for Indian tides. In 1882 G. H. Darwin took up harmonic analysis and produced memoirs which for a long time formed the standard manual on the subject, and about this time J. E. Pillsbury, of the U.S. coast survey, began the observations of currents by means of current meters. In 1885 C. Börgen introduced new ideas into the methods of harmonic analysis. Between 1870 and 1890 F. A. Forel made illuminating studies of the seiches of Lake Geneva, Switz., and about 1890 M. Margules investigated the dynamics of atmospheric tides.

From 1894 to 1907 R. A. Harris, of the U.S. coast survey, published his *Manual of Tides*. This work contained charts showing cotidal lines for the whole world, based on theories and hypotheses the leading feature of which was the principle of resonance. It was assumed that in each ocean there exist regions capable of free oscillation with a period near one of the principal tidal periods, and that the nature of these free oscillations may be calculated approximately, without allowing for the earth's rotation or the interaction with neighbouring regions.

After 1900 a number of Scandinavian oceanographers, notably V. W. Ekman, O. Pettersson and J. P. Jacobsen, invented current meters and L. Favé observed tidal elevations in the open sea by means of his self-registering instrument.

In 1912 A. Blondel applied the narrow sea theory, through the principle of least action, to the tides of the Red sea. From 1913 to 1920 R. Sterneck and A. Defant developed the narrow sea theory with special reference to the Adriatic sea. Defant applied this theory to the Red sea, the Persian gulf, the English channel and the Irish sea.

After about 1895 the dynamical theory of tides and seiches was much advanced by the mathematicians: H. Lamb, H. H. Hough, J. H. Poincaré, Lord Rayleigh, G. Chrystal, E. Fichot, G. R. Goldsbrough, G. I. Taylor, Harold Jeffreys, G. Bertrand, S. Goldstein and J. Proudman; between 1920 and the 1960s much was done on the analysis of observations by A. T. Doodson, K. Hessen and H. Rauschelbach.

### TIDE-GENERATING FORCES

**Dynamics of Earth-Moon System.**—The moon attracts every particle of the earth and ocean. By the law of gravitation the force acting on any particle is directed toward the moon's centre, and is jointly proportional to the masses of the particle and of the moon, and inversely proportional to the square of the distance between the particle and the moon's centre. If one can imagine the

earth and ocean subdivided into a number of small particles of equal mass, then the average, both as to direction and intensity, of the forces acting on these particles, is equal to the force acting on that particle which is at the earth's centre. If every particle of the earth and ocean were being urged by equal and parallel forces there would be no cause for relative motion between the ocean and the earth. Hence it is the departure of the force acting on any particle from the average which constitutes the tide-generating force. Now it is obvious that on the side of the earth toward the moon the departure from the average is a small force directed toward the moon; and on the side of the earth away from the moon the departure is a small force directed away from the moon. All around the sides of the earth along a great circle perpendicular to the line joining the moon and earth the departure is a force directed inward toward the earth's centre. Thus it can be seen that the tidal forces tend to pull the water toward and away from the moon, and to depress the water at right angles to that direction. In fig. 1 this distribution of forces is illustrated graphically. The relative magnitudes of the forces are given by the numbers on the figure, *M* being in the direction of the moon. The

FIG. 1.—TIDE-GENERATING FORCE

separate attractions of the moon at the earth's centre and at a point on the earth's surface are each inversely proportional to the square of the moon's distance, so that the difference between the two, which gives the tide-generating force, is approximately inversely proportional to the cube of the moon's distance.

The vertical component of the tide-generating force coincides in direction with the gravitational force of the earth itself, and thus acts as a slight modification of weight. This component does not tend to alter the position of equilibrium which the water would take up in the absence of any disturbance from an extraterrestrial body. The effective tide-generating forces, therefore, are the horizontal components of those indicated in fig. 1.

**Equilibrium Form of the Tide.**—For many purposes it is convenient to specify the distribution of the tide-generating forces at any instant by reference to a fictitious tide. If a completely rigid earth were completely covered by a layer of ocean, and if the tide-generating forces were to remain constant, there would be an invariable elevation of water at each point of the ocean surface and no tidal currents. If the distribution of forces were the same as that of the actual tide-generating forces at any instant, then the consequential elevation of water might be used as a specification of these forces. This distribution of fictitious tidal elevation is known as the equilibrium form of the tide. It is a real and accurate specification of the actual tide-generating forces throughout the earth's body as well as on its surface. When the equilibrium form is stated for every instant there is a complete specification of these forces, and henceforth the terms equilibrium tide and tide-generating force will be used interchangeably.

In this equilibrium form the inclination, to the horizontal, of the surface of the water would be always such that the consequential pressure gradient would everywhere balance the tide-generating force. It is therefore clear that the surface of the water would slope upward from *DD* toward the points *V* and *I*, the water being raised by a maximum amount at *V* and *I* and depressed by a maximum amount along the great circle through *DD*. The surface of

the water would be nearly that of an ellipsoid of revolution. The volume of this ellipsoid would be the same as that enclosed by the surface of the undisturbed ocean. Owing to the motion of the moon relative to the earth, the tidal ellipsoid moves over the earth so that  $V$  is always directly under the moon and  $I$  always directly opposite, while owing to the varying distance of the moon the equilibrium ellipsoid changes slightly in shape.

The tide-generating forces attributable to the sun's gravitation may be similarly specified. The sun's mass is nearly 27,000,000 times the moon's mass and the sun's distance is about 390 times the moon's distance from the earth. Consequently the sun's tide-generating forces are to those of the moon in the ratio of 27,000,000 to  $390^3$ ; i.e., .460 or  $\frac{1}{2.17}$ . This means that at corresponding points of the two ellipsoids representing the lunar and solar equilibrium forms the tidal elevations on the average will be in the ratio of 2.17 to 1.

**Harmonic Constituents.**—The study of tides on the earth has been greatly facilitated by the fact that the tidal motions, whether in the atmosphere, hydrosphere or lithosphere, are to a high degree of precision linear with respect to the tide-generating forces which cause them. This will be demonstrated later in the case of the dynamics of the ocean tide.

The significance of this linearity is that the tide-generating force can be considered as the sum of a number of constituents, the actual tide being the sum of the individual effects that each constituent would produce separately in the absence of all the others. As an example, the lunar and solar tides can be considered separately. The tide which would be produced under the combined action of moon and sun would be almost exactly what one would obtain by adding the separate contributions of moon and sun. In other words, there is little interaction between the lunar and solar tides.

The tide-generating forces can be expressed quite precisely by a finite series of harmonic terms, and in practice it has been found that about 30 terms generally give an adequate approximation. Furthermore, linear systems have the important property that their response is harmonic when they are acted upon by a force varying harmonically with time, the response having the same frequency as the force. The above two facts form the basis of the harmonic development of the tide, which has been in use since the time of Pierre S. Laplace.

Each term of the series representing the elevation of the equilibrium tide at some particular point on the earth's surface will be of the form  $H \cos(nt - \epsilon)$ , where  $t$  is time,  $H$  is the amplitude,  $n$  is the frequency or speed (commonly expressed in units of degrees per hour), and  $\epsilon$  is the epoch. For any given constituent the speed is constant, while the amplitude and epoch are constant in time but may depend on geographical location. The harmonic terms representing actual tides will be of the same form. In the case of the ocean tides  $H$  may represent the amplitude of the elevation of the water surface relative to the ground; for bodily tides  $H$  may represent the amplitude of a component of particle displacement; and for atmospheric tides  $H$  may represent the amplitude of a pressure fluctuation.

Let us now consider the effect of only one tide-generating body, such as the moon. As demonstrated in the previous section, the tide-generating forces of the moon can be specified completely by the shape and geographic orientation of the tidal ellipsoid, whose major axis is oriented along the line joining the centres of earth and moon. Now for the moment, let us consider what would happen if the moon remained at a constant distance from the earth and revolved about the earth in the equatorial plane with constant speed. An observer located at any given geographical position would experience two maxima and two minima of the equilibrium tide each lunar day. The amplitude would be a maximum at the equator and would decrease with increasing northern or southern latitude to a value of zero at the poles. The rise and fall of the equilibrium tide would be approximately harmonic with speed  $n = 2(\gamma - \sigma)$  where  $\gamma$  denotes the angular speed of the earth's rotation relative to the stars and  $\sigma$  the mean speed of revolution of the moon about the earth, and the equilibrium tide would be represented very closely by a single harmonic constituent. Since the

moon's speed of revolution is small compared to the earth's speed of rotation, the period of this constituent is approximately semidiurnal. The moon's varying declination (angular distance from equatorial plane), varying apparent angular speed of revolution about the earth and varying distance from the earth cause many modifications in this simplified example.

If the moon revolved about the earth with constant angular speed at some constant declination not equal to zero, one of the two poles of the equilibrium tidal ellipsoid would be always in the northern hemisphere, and the other in the southern hemisphere. The two equilibrium high waters that a point on earth not on the equator would experience as the earth rotates would therefore not be equal, and the introduction of a new constituent of speed  $n = \gamma - \sigma$ , approximately diurnal, would be required. This effect is known as the diurnal inequality. The variable declination of the moon results from the moon's motion in an orbit whose plane intersects the earth's equatorial plane at an angle  $i$ . The lunar declination thus passes through a monthly cycle but since both north and south declinations have essentially the same effect, i.e., that of decreasing the semidiurnal and increasing the diurnal contribution, the two constituents suffer a fortnightly modulation. Strictly speaking, such constituents cannot be considered harmonic, as there is implied in this term the invariability of amplitude, speed and epoch. These constituents can, however, be expressed precisely as the sum of a number of strictly harmonic terms, and more will be said about this point later.

The distance from earth to moon varies throughout a monthly cycle giving rise to a monthly modulation in the amplitude of the equilibrium tide. The maxima occur when the moon is at perigee, the point on the moon's orbit which is closest to the earth; the minima occur at apogee, when the moon is farthest from the earth. The time between successive lunar passages through perigee or apogee is the so-called anomalistic month, whose average length is 27.55 (mean solar) days. The speed of revolution of the moon about the earth varies inversely with the moon's distance according to Kepler's laws (see ORBIT). This causes the epoch of the equilibrium tide to vary according to the moon's position in its orbit, resulting in an apparent increase of period at apogee as compared to perigee. This monthly modulation of both amplitude and epoch of the equilibrium tide can again be expressed by a sum of purely harmonic constituents.

There are many other irregularities in the moon's motion, all of which can be expressed by the addition of more harmonic terms insofar as their effect on the equilibrium tide is concerned. The plane of the lunar orbit does not remain with constant orientation in space. Its movement is best described by the motion of the moon's nodes, which are the two points on the lunar orbit which lie on the plane of the ecliptic. Relative to the stars these nodes describe a westward motion known as the regression of the nodes, completing a cycle in about 19 years. Also, the major axis of the lunar orbit revolves eastward relative to the stars, completing a cycle in about nine years.

The solar effects are in every way analogous to the corresponding lunar effects.

**Species.**—In the above section it was seen that many cases arise where a constituent having a slow periodic variation of amplitude or epoch can be represented by the sum of two or more purely harmonic constituents. The speeds of these purely harmonic constituents will belong to the series,  $n \pm \omega$ ,  $n \pm 2\omega$ ,  $n \pm 3\omega$ , . . . , where  $n$  is the speed of the original constituent and  $\omega$  is the speed corresponding to the fundamental period of variation of its amplitude or epoch. If  $\omega$  is small as compared to  $n$ , the speeds of the purely harmonic constituents will cluster closely about the speed of the original constituent. In the case of the actual tide, most of the constituents are approximately semidiurnal, diurnal, or of a longer (fortnightly or longer) period of variation, and their amplitudes and epochs pass through a much longer period of variation than that of the actual constituent. As a result, the periods of purely harmonic constituents representing the equilibrium tide are clustered about 12 hr., 24 hr. and much longer periods, offering a logical basis for classification of the tidal constituents.

The scheme of classification shown in Table I was developed by

George Darwin in 1882 and has been adopted by most of the world's tidal authorities. Within any given species the coefficient is proportional to the equilibrium amplitude, and this proportionality holds roughly between constituents belonging to different species. The subscript on the symbol designating the constituent refers to the species to which it belongs. The long-period constituents have no subscript, the diurnal species have the subscript "one," the semidiurnal species the subscript "two." In addition to the constituents tabulated in Table I, there are terdiurnal, 4-diurnal, etc., constituents in the equilibrium tide, but these are of much lower amplitude and are not of much importance on earth.

TABLE I.—Tidal Constituents

Long-period species				
Symbol	Name	Speed	Speed in °/hr.	Coefficient
$M_f$	Lunar fortnightly . . .	$2\sigma$	1.098	.078
$S_{sa}$	Solar semiannual . . .	$2\eta$	.082	.036
—	Nineteen yearly . . .	$N$	.002	.033
Diurnal species				
$K_1$	Lunisolar . . .	$\gamma$	15.041	.265
$O_1$	Larger lunar . . .	$\gamma - 2\sigma$	13.943	.189
$P_1$	Larger solar . . .	$\gamma - 2\eta$	14.959	.088
Semidiurnal species				
$M_2$	Principal lunar . . .	$2(\gamma - \sigma)$	28.084	.454
$S_2$	Principal solar . . .	$2(\gamma - \eta)$	30.000	.211
$N_2$	Larger lunar elliptic . . .	$2\gamma - 3\sigma + \omega$	28.440	.088
$K_2$	Lunisolar . . .	$2\gamma$	30.082	.058

The earth's speed of rotation  $\gamma$  is the largest of all the parameters contributing to the speeds of the tidal constituents, and its numerical multiplier in the expression for the speed determines to which species a given constituent belongs. The other quantities in Table I which determine the speeds of the constituents are the mean motion of the moon  $\sigma$ , the mean motion of the sun  $\eta$ , the speed of revolution of the moon's nodes  $N$ , and the mean motion of the lunar perigee  $\omega$ . These quantities have a smaller effect and merely determine the period of the constituent within its species. It can therefore be said that the fundamental reason that the tidal constituents clump conveniently into species is that the day is much shorter than either the month or the year.

The equilibrium constituents of any given species all have the same geographical form. The long-period constituents are characterized by a standing wave symmetrical about the earth's axis. The polar regions oscillate in phase with each other and are  $180^\circ$  out of phase with the equilibrium tide in low latitudes. The two nodal lines lie along latitudes  $35.26^\circ$  north and south. The diurnal constituents have the form of a progressive wave rotating relative to the earth about its axis from east to west. At any given instant there are two maxima at opposite extremes of the earth and two minima similarly situated, all lying at latitudes  $45^\circ$  north and south on a great circle passing through the earth's poles. The amplitude of the diurnal equilibrium tide vanishes at equator and poles. The semidiurnal constituents also have the form of a progressive wave rotating about the earth from east to west. There are two maxima on the equator at opposite extremes of the earth and two minima also on the equator  $90^\circ$  from the maxima. The amplitude of the semidiurnal equilibrium tide is maximum at the equator and dies off with increasing latitude, vanishing at the poles.

**Description of the Constituents.**—Let us consider first the semidiurnal constituents. As can be seen from the value of their coefficients tabulated in Table I, the principal lunar constituent  $M_2$  is the most important. The other semidiurnal constituents "beat" against  $M_2$ , giving rise to a modulation the speed of which is equal to the difference of speeds of the two constituents. That is, the period of the modulation is the synodic period of the two constituents. The next strongest semidiurnal constituent is the principal solar constituent  $S_2$ , which beats against  $M_2$ , causing the fortnightly spring-reap modulation. Next comes the larger lunar elliptic constituent  $N_2$  which beats with  $M_2$ , causing a monthly modulation of the latter associated with the variable distance between earth and moon that results from the ellipticity of the moon's orbit. The lunisolar constituent  $K_2$  actually represents

the sum of two constituents, one of lunar and the other of solar origin, which cannot be separated from each other by analysis because their periods are equal. The lunar part of this constituent beats with  $M_2$ , giving rise to a fortnightly modulation associated with the variable declination of the moon. It will be recalled that the amplitude of the semidiurnal part of the tide is at a maximum when the tide-generating body has zero declination. Similarly the solar part of the  $K_2$  constituent beats with  $S_2$ , causing a semiannual modulation of this principal solar constituent which is associated with the variable declination of the sun.

The lunisolar diurnal constituent  $K_1$  is similarly composed of a lunar and a solar contribution. The lunar part of this constituent beats with the larger lunar constituent  $O_1$ , causing a fortnightly modulation associated with the variable declination of the moon. It will be recalled that the amplitude of the diurnal part of the equilibrium tide vanishes when the tide-generating body has zero declination. Similarly, the solar part of the constituent  $K_1$  beats with the larger solar constituent  $P_1$ , causing a semiannual modulation associated with the variable declination of the sun.

The constituents  $M_f$  and  $S_{sa}$  result from the variable declination of the tide-generating body and are at a maximum when this body is at zero declination. The lunar fortnightly constituent  $M_f$  thus reflects the variable declination of the moon, and the solar semiannual constituent  $S_{sa}$  similarly reflects the variable declination of the sun. In addition there is a small 19-year constituent which arises from the 19-year cycle in the regression of the moon's nodes, as well as many other minor long-period constituents.

In Darwin's harmonic development the tide-generating forces (the equilibrium tide) are not analyzed into strictly harmonic constituents; that is, the amplitudes and epochs of Darwin's constituents are not truly constant. They exhibit the 19-year cycle of the regression of the moon's nodes. However, during any one year the amplitudes and epochs vary so slightly that the constituents can be considered as true harmonic terms without incurring appreciable error. The nodal variation in amplitude is accounted for by taking the constituent coefficients  $c$  (those values tabulated in Table I) to be constant in time while denoting the true amplitude of the equilibrium constituents by the quantity  $fc$  where  $f$  is called the node factor and is the quantity which varies. The mean value of  $f$  is taken to be unity, and its values have been tabulated for each year for all important constituents. The value of  $f$  changes so slowly that it is adequate to take its mean value during any given year in place of its true value at any instant during that year.

In 1921 Doodson developed the equilibrium tide into a series of harmonic constituents whose amplitudes and epochs do not exhibit this 19-year cycle, and therefore do not need the artifice of node factors. For this reason it may be said that Doodson's development is more nearly perfectly harmonic than is Darwin's. Even though Doodson's development does not attempt to take into account such long-term variations as secular changes in the distance between earth, moon and sun, and geologic changes in sea level, it is doubtful that a more elaborate development will ever be needed for tidal work.

## DYNAMICS OF OCEAN TIDES

**Equations of Motion.**—The dynamical theory of tides introduced by Laplace in the 18th century has given much insight into the problem of tides in the ocean. The following assumptions and approximations are commonly introduced:

(1) The water is assumed to be homogeneous; (2) vertical displacements and velocities of the water particles are assumed small in comparison to the horizontal displacements and velocities; (3) the water pressure at any point in the water is given adequately by the hydrostatic law; i.e., it is equal to the head of water above the given point; (4) all dissipative forces are neglected; and (5) the ocean basins are assumed rigid (as if there were no bodily tide), and the gravitational potential of the tidally displaced masses is neglected.

If assumptions (1) and (3) are valid it can readily be shown that the tidal currents at any locality are uniform with depth.

Take  $a$  to denote the radius of the earth and  $g$  the acceleration of gravity at its surface. Position on the earth's surface will be

designated by the longitude  $\phi$  and the co-latitude (angular distance from the north pole to the point under consideration)  $\theta$ . Let  $h$  denote the depth of the ocean at any point, so that  $h$  is a function of  $\theta$  and  $\phi$ . Also, let  $\zeta$  denote the elevation of the free surface at any point of the ocean above its mean level, and  $u$  and  $v$  the southward and eastward components of the tidal current, so that these three quantities are functions of  $\theta$ ,  $\phi$  as well as of the time  $t$ . Then the equation of continuity, which expresses the condition that the volume of any mass of water must remain constant, may be written in the form

$$\frac{1}{a \sin \theta} \left\{ \frac{\partial}{\partial \theta} (hu \sin \theta) + \frac{\partial}{\partial \phi} (hv) \right\} + \frac{\partial \zeta}{\partial t} = 0 \quad (1)$$

provided that the elevation of the sea surface is everywhere small compared to the depth of water. If this is not the case then  $h$  must be replaced by  $h + \zeta$  in equation (1). This equation may be derived by expressing the condition that the net rate at which volume of water enters the sides of a vertical column is equal to the rate of increase of the volume at the top of this column by virtue of the time rate of increase of the elevation of the sea surface  $\zeta$ . Along a coast line the condition that the tidal current have no component perpendicular to the coast must be satisfied.

The equations of motion are formed by equating the southward and eastward components of acceleration of the water particles to the sum of all the forces per unit mass acting on the water in the southward and eastward directions, respectively. The acceleration consists of three parts: the local acceleration; the field acceleration; and the Coriolis acceleration resulting from the earth's rotation. As an example, the southward component of acceleration is equal to

$$\frac{\partial u}{\partial t} + \frac{u}{a} \frac{\partial u}{\partial \theta} + \frac{v}{a \sin \theta} \frac{\partial u}{\partial \phi} - \frac{v^2}{a} \cot \theta - 2\omega v \cos \theta$$

where the first term represents the local, the second, third and fourth terms combined represent the field, and the last term the Coriolis accelerations, respectively. Here  $\omega$  represents the angular speed of the earth's rotation. At this point an additional assumption shown to be valid for tidal motion in true oceanic regions is introduced: that the field acceleration is negligible as compared to the local acceleration. In accordance with the foregoing approximations, the only forces acting on the water are the tide-generating forces and those attributable to the pressure gradient resulting from the slope of the sea surface. The southward and eastward components of the pressure gradient are given by

$$\frac{\rho g}{a} \frac{\partial \zeta}{\partial \theta}, \quad \frac{\rho g}{a \sin \theta} \frac{\partial \zeta}{\partial \phi},$$

$\rho$  being the water density, and the southward and eastward components of the tide-generating force are given by

$$\frac{\rho g}{a} \frac{\partial \bar{\zeta}}{\partial \theta}, \quad \frac{\rho g}{a \sin \theta} \frac{\partial \bar{\zeta}}{\partial \phi},$$

where  $\bar{\zeta}$  represents the elevation of the equilibrium tide. This quantity is a function of  $\theta$ ,  $\phi$  and  $t$  and is assumed known as it can be deduced from knowledge of the relative movements of the earth, moon and sun. The equations of motion can then be written in the form

$$\begin{aligned} \frac{\partial u}{\partial t} - 2\omega v \cos \theta &= -\frac{g}{a} \frac{\partial}{\partial \theta} (\zeta - \bar{\zeta}) \\ \frac{\partial v}{\partial t} + 2\omega u \cos \theta &= -\frac{g}{a \sin \theta} \frac{\partial}{\partial \phi} (\zeta - \bar{\zeta}). \end{aligned} \quad (2)$$

The equations (1) and (2) serve to determine completely, at least in theory, the tidal currents and elevation over the entire oceans and for all times, given a complete description of the tide-generating forces and the boundaries of the ocean basins. In practice, however, such a general solution has never been obtained owing to the complicated nature of the distribution of sea and land masses and the varying depth of water. For this reason tidal research has been based primarily on observations and general principles (such as linearity, etc.) derived from theory.

It may be noted that these equations are linear in  $u$ ,  $v$ ,  $\zeta$  and  $\bar{\zeta}$  with the result that the tide-generating forces may be separated into several constituents, the sum of whose effects is exactly equivalent to the effect produced by the sum total of all the tide-generating constituents. Indeed, as has already been pointed out, this is the basis of the harmonic development of the tide. Let us review under what conditions the ocean tide is truly linear and under what conditions this linearity breaks down. Unless the elevation of the sea surface above its mean position is always small as compared to the mean depth  $h$ , equation (1) becomes nonlinear. Similarly, if the field acceleration becomes so large it is no longer negligible as compared to the local acceleration equations (2) become nonlinear. This is most likely to occur in regions of large tidal currents with a large spatial rate of change (current shear). Nonlinear dissipative forces may be another source of nonlinearity. All these effects are quite small in the vast oceanic regions but tend to become larger in regions of shallow water and in the vicinity of the coast line, and consequently are referred to as shallow-water tides.

As to the other approximations, that of neglecting all dissipative mechanisms (4) is not a very good one, but more will be said about this point in the section on *Tidal Friction*. The bodily tides of the earth invalidate to a certain extent assumption (5) by virtue of a small variable movement of the sea floor and of the earth's own gravitational field. If  $\zeta_0$  designates the variable elevation of the sea floor above its mean position, equation (1) will stand unaltered if we take  $\zeta$  to denote the elevation of the sea surface relative to the sea floor, but in the formulas for pressure gradients  $\zeta$  must be replaced by  $\zeta + \zeta_0$ . The disturbance in the gravitational forces brought about by the displacements of water and solid earth must be accounted for by adding a term  $\bar{\zeta}_0$  to  $\bar{\zeta}$ . Inhomogeneities in the sea water have been neglected according to assumption (1), but may have a more important effect in tidal motions than has been anticipated. At any given time of the year a large part of the ocean is covered by a nearly homogeneous layer of light, warm water 50 to 200 m. thick. Such stratification of the sea water may influence the vertical structure of the tidal current with resulting deviations from their generally assumed uniformity with depth. Bottom friction will also introduce vertical shear in the tidal current.

Suppose now that we consider the ocean's response to one harmonic constituent of the equilibrium tide. If we take a long-period constituent,  $\bar{\zeta}$  will have the form of a standing wave over the entire earth. A constituent of any other species will have the form of a progressive wave rotating relative to the earth about its axis in the westward direction. Such progressive waves can, however, be expressed as the sum of two standing waves separated in longitude by  $90^\circ$ , and separated in time also by  $90^\circ$ . In any case, therefore, it will suffice to express  $\bar{\zeta}$  in the form

$$\bar{\zeta} = H_0 \cos n(t - \tau_0)$$

where  $n$  and  $\tau_0$  are absolute constants and  $H$  is a function of geographic position but independent of time. The actual response of the ocean will then be the sum of a number of solutions to such inputs. The solutions for the tidal elevation  $\zeta$  and current  $u$ ,  $v$  from equations (1) and (2) will have the form

$$\begin{aligned} \zeta &= H \cos n(t - \tau) \\ u &= U \cos n(t - \tau_1), \quad v = V \cos n(t - \tau_2), \end{aligned}$$

where  $H$ ,  $U$ ,  $V$ ,  $\tau$ ,  $\tau_1$ , and  $\tau_2$  are all functions of geographical position only. While it is not feasible to actually determine these functions analytically, if their values are determined for a certain location on the earth by appropriate analysis of tidal observations, the response to the constituent under consideration could be predicted for all time. In the case of the tidal elevation, wherever  $H$  and  $\tau$  have been determined for all important constituents, the tidal elevations there can be predicted for any time. It may be remarked that at a given place  $H_0$  and  $H$  are generally quite different; i.e., the true tide bears little resemblance to the equilibrium tide.

**Nonlinear Distortion (Shallow-Water Tides).**—At places

where the tidal elevation becomes appreciable as compared to the water depth, or other nonlinear effects occur, the principle of superposition breaks down. One might think that under these circumstances the concept of harmonic constituents would be completely useless, but it has been found possible to retain this concept provided that additional constituents, the so-called shallow-water tides, be included. The regions where this phenomenon occurs are generally confined to rivers, estuaries and shallow gulfs. The shallow-water constituents are not produced by the direct action of the tide-generating forces, but by the distortion, attributable to shoal water, of already existing tidal constituents which have been formed in the ocean. In fact, if the region of distortion is small enough (as it usually is), the tide-generating forces have little or no direct effect on the shallow-water tide.

It is no longer correct to consider separately the reactions to individual equilibrium constituents, but let us take the simple example of only one equilibrium constituent in order to gain insight into the problem. The response of a nonlinear system to the harmonic forcing constituent will not be harmonic, but at least it will be periodic, having the same period as the forcing or primary constituent. If  $2\pi/\sigma$  is the period of the primary constituent, it is well known from the theory of Fourier series that a periodic function of this period can be expressed as the sum of purely harmonic terms having speeds  $\sigma, 2\sigma, 3\sigma$ , etc. Extending this idea to the actual situation one should expect to find shallow-water constituents having periods of one-half, one-third, etc., of those of the major tidal constituents. The shallow-water constituents obtained in this way are called overtones because of their analogy to overtones in acoustics. The same symbol is used to designate these overtones as is used to designate the equilibrium constituent which gives rise to them, and again the subscript designates the species (approximate number of periods in a day) to which the overtide belongs. For example the constituent  $M_2$  gives rise to the series of overtones  $M_4, M_6$ , etc., and  $K_1$  gives rise to the overtones  $K_2, K_3$ , etc. In some cases an overtide will have exactly the same period as another equilibrium constituent and it will be impossible to separate the two by harmonic analysis. For example,  $K_2$  represents the lunisolar semidiurnal constituent, but an overtide of exactly the same period as  $K_2$  is produced by nonlinear distortion of the lunisolar diurnal constituent  $K_1$ . In this and in similar cases the symbol  $K_2$  (referring to the actual tide) represents the combined effect of both the linear reaction to the equilibrium constituent  $K_2$  and the overtide.

The theory of progressive shallow-water waves of finite height has been used to estimate the relationship between the amplitudes of the overtones and primary tide. The amplitude of the  $n$ th overtide is found to be proportional to the  $n$ th power of the amplitude of its primary at any given place, as the amplitude of the primary varies in time. For example, if the range of the semidiurnal tide is twice as great during the spring tides as during the neap tides, the range of the quarter-diurnal overtide resulting from distortion of the semidiurnal tide will be approximately four times as great during the spring tides as during the neaps. The range of the 6-diurnal overtones will be eight times as great during the spring tides, etc. As to the 19-year nodal variation in amplitude, the node factors  $f$  of the overtones bear a relation to those of the primary as illustrated in the following example in the case of the overtones of the constituent  $M_2$ :

$$f(M_4) = [f(M_2)]^2, \quad f(M_6) = [f(M_2)]^3, \text{ etc.}$$

The above relations seem to be confirmed fairly well in most cases by tidal observations in spite of the fact that assumptions in the theory from which they have been derived are far from fulfilled. For example, in many regions where overtones are important, such as some rivers and estuaries, the tidal wave has more nearly the form of a standing wave than that of a progressive wave, but the theory for standing shallow-water waves of finite height has not been adequately developed. Also, the nonlinear effects caused by one constituent cannot, strictly speaking, be superimposed on those caused by another.

The nonlinear interaction between two or more primary constituents can be accounted for by the inclusion of compound con-

stituents. In the case of two interacting primary constituents having speeds  $\sigma_1$  and  $\sigma_2$ , a series of compound constituents will result, having speeds  $\sigma_1 \pm \sigma_2, \sigma_1 \pm 2\sigma_2, 2\sigma_1 \pm \sigma_2$ , etc., including all possible combinations of the form  $a\sigma_1 \pm b\sigma_2$ ,  $a$  and  $b$  being integers. The relationship of the amplitudes of the compound constituents to those of their primaries has been approximated by assuming that the system responds like a power-law filter; i.e., like a system whose output is equal to a polynomial function of the input. In this way the relative importance of the compound constituents of any given species as well as the dependence of their node factors on those of the primary constituents can be evaluated. No general conclusions can be drawn concerning the relative importance of two compound constituents belonging to different species.

TABLE II.—Shallow-Water Constituents

Symbol	Speed	Speed in °/hr.	Node factor
$2SM_1$	$2\gamma + 2\sigma - 4\eta$	31.016	$[f(M_1)]^2$
$MNS_2$	$2\gamma - 5\sigma + 2\eta + \omega$	27.424	$f(M_2)$
$MK_1$	$3\gamma - 2\sigma$	44.025	$f(M_2)f(K_1)$
$MK_2$	$3\gamma - 4\sigma$	42.927	$[f(M_2)]^2 f(K_2)$
$M_4$	$4\gamma - 4\sigma$	57.068	$[f(M_2)]^4$
$MS_4$	$4\gamma - 2\sigma - 2\eta$	58.984	$f(M_4)$

Table II includes the more important shallow-water constituents, both overtones and compound constituents. In the table, only two of each of the semidiurnal, terdiurnal and 4-diurnal shallow-water constituents are given for illustration, but there are ports for which many others would be needed to give an accurate representation of the tide. In fact for some ports the number of these constituents that would be needed is so high that the harmonic method becomes impractical. It may be noted that the two terdiurnal constituents listed in Table II are given the same symbol. Actually there is some confusion as to the designation of the compound constituents. The designations given in Table II are based on the nomenclature used by the United States coast and geodetic survey.

### ACTUAL TIDES IN THE OCEAN

**Progressive Tides in Canals.**—Let us consider a long narrow canal, open at both ends, along which a tidal wave is progressing. In accordance with the well-known properties of progressive waves, the water particle velocity at the crests of the wave will be in the same direction as that of the propagation of the wave form, while the water particle velocity at the troughs will be in the opposite direction.

Now, the rotation of the earth tends to deflect any particle in motion to the right (in a horizontal plane in the northern hemisphere) relative to the earth with an acceleration proportional to the speed of the particle. This is the so-called Coriolis acceleration that was discussed above. In order to balance this Coriolis acceleration the water surface at the crest must slope upward to the right (in the northern hemisphere), if one is facing in the direction of propagation of the wave. Similarly, the water surface at the trough must slope upward toward the left. Therefore, the crests are higher and the troughs lower along the right coast of the canal, and at any point on the right coast of the canal there will be a higher range of the tide than for a point situated on the left coast.

The above considerations are substantiated by tidal observations in the English channel and Irish sea. The tidal wave progresses eastward through the English channel passing out through the Straits of Dover into the North sea. The tidal range is greater on the French coast (the right side) than on the English coast. In the Irish sea, the tidal wave progresses northward, and the tidal range is greater on the English and Welsh coasts (again the right side) than on the Irish coast.

**Tides in Adjacent Seas.**—If the region under consideration is small enough the tide within it is influenced predominantly by the tide immediately outside the region and not appreciably by the direct action of the tide-generating forces. It is on the water of the great oceans that the gravitational forces of the moon and sun generate the greater part of the tide, while the tides in the small seas bordering the oceans can be considered as free waves.

A great deal of theoretical work has been done on the tides of adjacent seas, but invariably it is necessary to approximate the sea by some simple geometric shape. Nevertheless, many satisfactory explanations of the actual tide in small bodies of water have been obtained.

The theory of free long waves states that a tidal wave in a narrow canal of constant depth is propagated with a velocity of  $\sqrt{gh}$ , the wave length being given by the expression  $T\sqrt{gh}$ , where  $g$  is the acceleration of gravity,  $h$  is the water depth and  $T$  is the period of the wave (time interval between successive high waters). In the case of the tide,  $T$  will have approximately the value of 12 hr. for the semidiurnal tide, or 24 hr. for the diurnal tide.

Let us neglect, for the time being, the effect of the earth's rotation and consider a tidal basin of constant depth having rectangular shape with one end closed and the other end in communication with the ocean. Only motions parallel to the length of the basin will be considered. The tides within the basin are influenced by the boundary conditions (1) that the elevation at the mouth of the basin is at any instant the same as that in the ocean immediately exterior to the basin; and (2) that the horizontal orbital motion at the closed end vanishes. The situation is analogous to the acoustical problem of stationary oscillations within an organ pipe open at one end. The spatial distribution of amplitude of the oscillation is characterized by the positions of nodes, or places where there is no tidal oscillation of the water surface, or no pressure oscillation in the case of the organ pipe, and of antinodes or places where the oscillations attain their maximum amplitude. A standing wave in the pipe has an antinode at the closed end, while one quarter of a wave length away there is a node, and so forth, with nodes and antinodes alternating along the length of the pipe with a quarter of a wave length between them. If the open end is at or near a node the oscillation within the pipe attains a magnitude much greater than that outside the mouth of the pipe, and resonance is said to occur. Thus, in the case of the rectangular tidal basin, resonance would occur if the length  $L$  of the basin had any of the values

$$\frac{1}{4}T\sqrt{gh}, \frac{1}{2}T\sqrt{gh}, \frac{3}{4}T\sqrt{gh}, \text{ etc.}$$

Or, for a given length, resonance would occur if the period of oscillation had any of the values

$$\frac{4L}{\sqrt{gh}}, \frac{4L}{3\sqrt{gh}}, \frac{4L}{5\sqrt{gh}}, \text{ etc.}$$

but in actual practice the successive values have diminishing importance and usually only the first one, corresponding to a quarter wave-length basin, is considered. This is called the gravest free mode.

If the basin is less than a quarter of a wave length long, the entire basin oscillates with the same phase. If the length of the basin is between a quarter wave length and a half wave length there is one nodal line and the oscillation at the head of the basin is 180° out of phase with that at the mouth. Every node line represents a phase change of 180°.

The Bay of Fundy on the east coast of North America has the greatest tidal range of any place on earth, and this fact is attributed to a resonance phenomenon based on the foregoing considerations. The shape of the Bay of Fundy is reasonably well

approximated by a rectangular basin having a length of 170 mi. and a depth of 240 ft. The above relationships indicate that such a basin would have a resonance period of approximately 12½ hr. which is very close to that of the semidiurnal tide. It should therefore be expected that the semidiurnal tide would be greatly magnified relative to the diurnal, and this is found to be the case. At certain places at the head of the bay the spring tide attains a range of 50 ft.

Elongated seas of variable depth and cross-sectional area also can be studied mathematically provided these quantities vary slowly enough along the length of the sea. Good agreement between theory and observation has been obtained for tides in the Gulf of California, the Red sea and other adjacent seas. The Gulf of California is computed to have a resonance period of approximately 25 hr., roughly that of the diurnal tide. The tide at the head of the gulf near the mouth of the Colorado river has been observed to be predominantly diurnal in character with a maximum range of approximately 20 ft. The computed variation of amplitude and phase of the  $M_2$  constituent in the Red sea is in good agreement with the observed variation, and both theory and observations indicate the presence of a nodal line close to Port Sudan, near the mid-point of the sea's length.

To consider geostrophic effects (*i.e.*, those resulting from the earth's rotation) it is necessary to take into account the Coriolis acceleration. Consider a standing oscillation in a gulf as shown in fig. 2A at the instant of high water at the head of the gulf. The curve  $A$  has been drawn through all points where the deviation of the water level from its mean is zero at this instant. One quarter period later the water is flowing out of the gulf. At this instant, in the absence of the Coriolis force, the elevation everywhere within the gulf would have its mean value (except for a small frictional effect), and the curve  $A$  would represent a nodal line. Actually, the elevation will be higher to the right of the outward flowing current, as is shown in fig. 2B, with the curve  $A'$  lying along points whose elevation is at the mean level. Continuity considerations show that there must have been currents flowing at the instant of high water within the gulf in order to produce the distribution of water level shown in fig. 2B. Possible directions for these currents are shown in fig. 2A.

At the intersection of the curves  $A$  and  $A'$  there will be no rise and fall of sea level, and such a point is known as an amphidromic point. Let it be assumed that the constituent under consideration

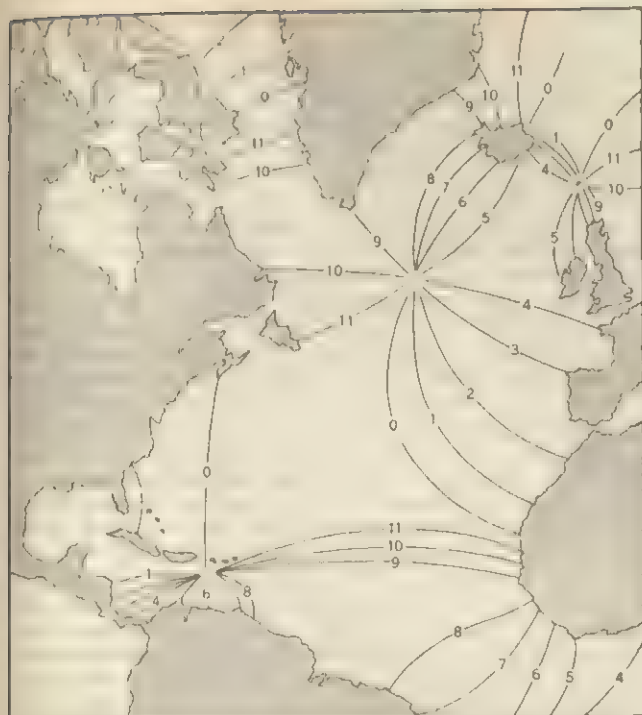

FIG. 2.—MOVEMENT OF THE TIDES IN A GULF.  $H$  INDICATES HIGH-WATER LEVEL,  $L$  LOW-WATER LEVEL. (SEE TEXT FOR FURTHER EXPLANATION.)

FIG. 3.—COTIDAL LINES FOR  $M_2$  CONSTITUENT IN BRITISH SEAS. NUMBERS GIVE GREENWICH MEAN LUNAR TIME OF HIGH WATER

is a semidiurnal one, and divide its period into 12 equal time intervals called constituent hours, and let the zero constituent hour

FIG. 4.—COTIDAL CHART OF THE ATLANTIC OCEAN

correspond to the instant of high water within the gulf as depicted by fig. 2A. Fig. 2C then gives the curves along which high water occurs for each of the 12 constituent hours. Such curves are called cotidal lines. The hypothetical distribution of range of tide is indicated by the dashed curves, called corange lines, each of which connects points having equal range of tide. The amphidromic point, at which the tidal range is zero, lies in the centre of the concentric family of corange lines. The cotidal lines indicate the position of the crest of the tidal wave at any instant, and it is seen that this crest rotates in counterclockwise fashion (in the northern hemisphere) about the amphidromic point. Such amphidromic systems with counterclockwise movement of the tidal crest are characteristic also of the oceans and adjacent (large) bodies of water.

**Geographical Distribution of the Ocean Tide.**—Cotidal maps, such as the one described above, are useful in illustrating the distribution of tidal elevation in a body of water, but it should be kept in mind that such charts are, strictly speaking, useful only in describing a single harmonic constituent. In theory it would be necessary to have one complete cotidal map of the world's oceans for each and every tidal constituent in order to characterize completely the form of the tidal wave, or the rise and fall of water at every point in the ocean. The only constituent for which such charts have been prepared, to any extent, has been the  $M_2$  constituent, which is somewhat representative of the other semidiurnal constituents.

Except along the boundaries of the oceans the tidal elevations are extremely difficult to measure, and what meagre knowledge we have of the geographic distribution of the tide in the whole ocean has been deduced principally by extrapolating from coastal tide stations and, where possible, making use of tidal current measurements. The equations of motion connect the tidal currents with the elevation gradients and external forces, including those of friction and so from a knowledge of the currents and a law for the frictional forces the elevation gradients can be calculated. When the elevation is also known at a particular point, the directions of the cotidal and corange lines and also the distance apart of neighbouring members of these families of lines can be calculated. Such conditions are fulfilled for many coasts. If the elevation gradients can be calculated along a line which passes through one or more points at which the elevation is known, it is clear that the elevation can be calculated all along the line. In this way the semidiurnal

( $M_2$ ) tide over the North and Irish seas was determined by Proudman and Doodson in 1923 (see fig. 3).

Cotidal charts for the  $M_2$  constituent have been prepared for the oceans but they are uncertain, however, especially at large distances from the coasts and islands where tide gauge observations have been made. Tidal current determinations are rarely made in the open ocean. Another difficulty is that tide gauges are frequently located in sheltered bays or atoll lagoons where the time of high water may be delayed by as much as several hours. The cotidal chart of the Atlantic ocean shown in fig. 4 was prepared by Sterneck in 1920.

Mathematical solutions for the tide in ocean basins of simplified shapes have been obtained. Laplace in 1776 studied the dynamical problem of the semidiurnal tide in an ocean covering the entire earth and having constant depth. His solution takes into account the inertia of the water and the rotation of the earth. Some interesting aspects of this solution are summarized in Table III.

TABLE III.—Laplace's Solution of the Dynamical Problem of the Semidiurnal Tide

Depth (fathoms)	Ratio of elevation to equilibrium elevation at equator	Depth (fathoms)	Ratio of elevation to equilibrium elevation at equator
1,210	—7.4	4,840	11.5
2,420	—1.8	9,680	1.9

Positive values in the second column indicate that the tide at the equator is direct—that is, that high water occurs simultaneously with high water of the equilibrium tide. Negative values indicate that the tide is inverted, or  $180^\circ$  out of phase with the equilibrium tide. For the diurnal tide Laplace obtained the curious result that there is no tidal oscillation of elevation on this worldwide ocean of constant depth, although there are tidal currents.

Several solutions have been obtained for the special case of an ocean of constant depth bounded by two meridians. The result of one of the solutions obtained by Proudman and Doodson is shown in fig. 5, which represents a cotidal chart of the  $K_2$  tide in an ocean of depth 14,520 ft. bounded by meridians  $70^\circ$  apart. The  $K_2$  tide was selected because of mathematical simplifications, but the  $M_2$  tide should be quite similar. Comparison of fig. 5 representing a mathematical solution with fig. 4 derived from observations discloses no striking similarities except for the general occurrence of amphidromic systems.

**Tides in Lakes.**—If all natural periods of oscillation of a completely enclosed basin are short as compared to those of the tidal constituents, the tide should be approximately at equilibrium with the tide-generating forces at all times. According to the theory of long-standing waves in a rectangular basin of constant depth, the length of the basin is equal to one-half wave length of its gravest free mode. The period of the gravest mode is given by the expression  $2L/\sqrt{gh}$  where  $L$  is the length of the basin. For example, the gravest mode of a lake 20 km. long having constant depth of 40 m. will have a period of approximately  $\frac{1}{2}$  hr. according to the above formula, and the tide in such a lake would there-

FROM A. T. DOODSON AND H. D. WARBURG, "ADMIRALTY MANUAL OF TIDES", REPRODUCED BY PERMISSION OF THE CONTROLLER, HER BRITANNIC MAJESTY'S STATIONERY OFFICE

FIG. 5.—COTIDAL CHART OF A HYPOTHETICAL OCEAN OF CONSTANT DEPTH BOUNDED BY MERIDIANS SEPARATED BY  $70^\circ$

fore be determined with quite sufficient accuracy by static principles.

If the above condition is fulfilled the slope of the lake's surface is equal, at any instant, to the slope of the equilibrium tide at that location, and the actual tidal elevation at any point within the lake is determined by the condition that the total volume of water remain constant. The tide will usually differ considerably from the equilibrium tide according to these conditions, generally being considerably smaller in amplitude. For example, the maximum slope of the equilibrium tide is of the order of a metre in one-fourth the earth's circumference, 10,000 km., giving a value of  $10^{-7}$ . For a lake whose length is 10 km. the maximum difference of elevation between its extremes will be of the order of  $10 \times 10^{-7}$  km. or 1 mm. The tide in small lakes is thus seen to be extremely small, and is usually overshadowed by other effects such as a variable amount of water volume related to variable runoff and evaporation, wind effects, seiches, etc.

There is no variation of tidal elevation at the centroid of the lake's surface area. If the gravest free oscillation of the lake approaches that of the semidiurnal tide, then of course the above concepts no longer are true, and a dynamical treatment of the problem is necessary. This elementary discussion has also omitted two other important effects: the yielding of the lake's bottom with the tidal deformation of the earth's body, and the potential of the tidally displaced matter of the earth (*see* section X).

### TIDAL ANALYSIS AND PREDICTION

**Tidal Observations.**—Probably the greatest achievement of tidal study is that it has been made possible to predict to a fair degree of accuracy what the sea level would be at any desired time for a great number of ports. The method used is essentially the following: The constants in the harmonic development of the tide at any place are determined by analysis of a long series of observations at that place. Knowing the values of these constants, it is possible to reconstruct or synthesize the tide for any past, present or future time. This is the harmonic method, and it can be applied to any observable tidal quantity which depends linearly on the tide-generating forces, such as the north or east components of the tidal current (not the speed or the direction of the current), the tidal variations of gravity or atmospheric pressure, etc.

The theoretical problem of the tide in the oceans has not been solved, and knowledge of the tide at any place depends on some observations having been made at the place. The prediction process may be loosely considered as one of extrapolation of the observations. It is possible that at some future time tidal theory will have been advanced sufficiently that full knowledge of the tide at a given place may be obtained theoretically without the need of previous observations at the place.

Observation of the variable elevation of the sea surface is carried out by means of an instrument called a tide gauge, which usually consists of a float and pulley system so arranged that the height of the float determines the position of a recording pen on a moving chart. The chart is made to move at constant speed by means of a clock mechanism, so that in the result one obtains a graph of the height of sea level as a function of time. Such a graph is called a marigram.

The float is usually suspended within a vertical pipe or well having a small orifice at the bottom in order that the float not be subjected to rapid erratic motions by the ocean waves. A pier piling is an ideal structure on which to fasten the tide well. The diameter of the orifice and the inner cross-sectional area of the tide well determine the frequency response of the gauge. The orifice must be small enough to insure that the ordinary high-frequency ocean waves have greatly reduced amplitude within the well, but large enough so that no appreciable lag be introduced in case of the tide. The frequency response of the tide gauge is usually arranged so that fluctuations of water level taking place over five minutes or longer are quite faithfully reproduced on the marigram, so that the gauge may be useful in recording tsunamis (seismic sea waves) and other such phenomena. The gauge is periodically levelled in with a series of bench marks located nearby on the land in order to compensate for any long-period changes in the height of the

gauge as a whole that might be brought about by slow sinking of the pier on which it is fastened, etc. In this way the gauge is useful for studying extremely long-period phenomena such as the year to year variation of mean sea level.

After the marigram is obtained, the usual procedure is to read off at hourly intervals the height of sea level, and to correct these hourly tidal heights for any variation of datum that may have occurred. Vast quantities of these hourly tidal heights for many seaports are on file at the world's principal tidal agencies.

**Analysis of Observations.**—If a long enough series of observations has been obtained from a locality, it is possible to determine the harmonic constants for each important tidal constituent with good accuracy. The procedure for finding the harmonic constants for any one constituent will be illustrated in the case of the principal solar series,  $S_1$ ,  $S_2$ ,  $S_4$ , whose periods are exactly 24, 12 and 6 hr. At instants of time separated by 24 hr. each constituent of this series will have the same value. Let us assume that we have a whole year of data. If we take the average of the 365 hourly tidal heights corresponding to the zero hour of each day, the resulting value will be practically free from the effects of all the other constituents whose periods are not submultiples of 24 hr., because their phases will differ from the zero hour of one day to the zero hour of the next day. Such a constituent will sometimes have positive values on the zero hour, and another day it will have a negative value, and on the average its value will be close to zero. The constituents of the principal solar series, on the other hand, will have the same value, on the average of all the zero hours, as for the zero hour of any given day. This averaging is repeated for each of the 24 hr. of the day and in the result one obtains a complete daily cycle of the combined effect of the constituents  $S_1$ ,  $S_2$ ,  $S_4$  practically free of the effects of the other constituents. The amplitudes and epochs of each of the constituents of this series can now be found by the well-known methods of harmonic analysis.

For constituents other than those of the principal solar series the averaging must be carried out in similar fashion but based on the fundamental period of the constituent under consideration instead of 24 hr. Here there is a slight complication if the data are tabulated in the form of hourly tidal heights, as the times for which the tidal values are needed do not coincide exactly with the times at which the values are tabulated. In this case it is customary to use the tabulated value in closest proximity to the time for which the value is actually needed, and it is seen that the error in time will never exceed 30 min. The small error incurred in this process can be corrected by applying an augmenting factor.

If the series of observations is short it is not possible to separate completely any given constituent from the disturbing effects of the others. However, the harmonic constants of all the constituents can be determined approximately, using the above technique, and a first order correction can then be applied. This process is called elimination.

**Inference of Harmonic Constants.**—It is impractical to use the method discussed above for a constituent whose amplitude is small as compared to possible errors arising from various sources. The harmonic constants of such a constituent are usually inferred from those of one of the major constituents having approximately the same period. Such inference is based on the supposition that the ocean's response to a periodic tide-generating force varies continuously and relatively slowly with the period of the force. Hence it is assumed that two equilibrium constituents whose periods are nearly equal will cause tidal constituents in the ocean at any given locality, whose amplitudes are proportional to those of the equilibrium constituents causing them.

It is best to infer harmonic constants of a given constituent  $X$  from those of one of the most important constituents whose period is as close as possible to that of  $X$ . Suppose that the constituent  $M_2$  meets these requirements. If  $H$  represents the actual amplitude of the constituents and  $c$  their constituent coefficients (which are proportional to the amplitudes of the equilibrium constituents), the relationship

$$\frac{H(X)}{c(X)} = \frac{H(M_2)}{c(M_2)}$$

is used to relate the amplitudes of  $X$  and  $M_2$ . The epochs (intervals by which the oceanic constituents lag behind their equilibrium counterparts) can be set equal, to a first approximation, while a more refined method of estimating the epoch of constituent  $X$  is given in *Special Publication 98*, U.S. coast and geodetic survey. The constituent coefficients have been precisely determined from astronomic observations, and if the amplitude and epoch of  $M_2$  have been determined from tidal observations, the amplitude and epoch of  $X$  can be calculated from the above relationships. The validity of the above relations can be checked by also evaluating the constants of  $X$  by conventional means, and it is usually found that the inference method gives fair results if the periods of the two constituents are nearly equal. It should be emphasized that the inference method can never be used to relate the constants of constituents belonging to different species.

**Prediction: Tide Tables.**—For many purposes it is of great importance to know in advance the times and heights of high water at a particular place on a particular day. Consequently governments and harbour authorities publish, a year or so in advance, tables giving such information for all the principal ports of the world. In a few cases tables are similarly published giving the height of water above some datum at every hour of the year, while for a certain number of navigable channels tables of the times of slack water are also issued.

The standard method of tidal prediction is the harmonic method based on the idea of harmonic constituents, and the necessary information for any particular place is provided by the process of analysis discussed above. The only theoretical results which are utilized in tidal prediction are (1) the decomposition of the entire tide-generating force as the sum of a number of harmonic equilibrium constituents; and (2) the linearity of the ocean tide. Thus, the periods of the constituents are obtained from the observed motions of earth, moon and sun, while their amplitudes and epochs are obtained from tidal observation: tidal prediction is largely an empirical science.

The process of harmonic prediction consists of the calculation of the value of each harmonic constituent for a given time, and then the addition of the values obtained for all the constituents. When this is done for every hour of a year, the computational task becomes enormous, and to obviate this, special computing machines, called tide-predicting machines, have been constructed. Those in use at mid-20th century were of the analogue type and usually consisted of a series of gears or pulleys by which means the analogue addition of the constituents could be carried out. The amplitude and epoch of each constituent could be adjusted into the machine so that it could be used for any location and for any tidal quantity. Of course, only that part of the rise and fall of the sea surface related to astronomical quantities can be predicted, and hence any individual prediction is liable to differ considerably from the actual occurrence, as will be seen below.

#### NONASTRONOMICAL VARIATIONS OF SEA LEVEL

**"Geologic" Tides.**—Any change in shape of the ocean basins or in the total quantity of water in them can bring about changes of level at a given locality. Another effect, however, is to change the dynamical response of the oceans to the tide-generating forces, and we should consequently expect the tidal harmonic "constants" to change.

The geological change in sea level is quite slow as compared to that effected by the moon and sun, and is manifested by a small year to year variation in mean annual sea level. There is evidence that the average sea level over the entire earth rose by the order of 10 cm. from 1850 to 1950. This has been related to a shrinking of the ice caps of the world, particularly those over Antarctica and Greenland. About 1000 B.C., during the postglacial temperature maximum, sea level probably stood about 5 m. above its present level. At the present time there are localities where the average annual sea level is rising and others where it is falling, and this is attributed to a relative downward or upward motion of the land area in the vicinity. The horizontal extent over which these year to year sea level records appear similar gives a good indication as

to the size of the portions of the earth's crust that are sinking and rising. Actually, the similarity extends over many hundreds of kilometres, indicating that masses somewhat smaller than continents are moving as a whole.

Variation of the tidal harmonic "constants" by the processes just described is probably a slow process, and it may be doubted that a detectable change would occur within tens of thousands of years. At locations where the tidal constants depend critically on the local, small-scale topography, however, this is not the case. For example, the tide up a river may depend critically on the conditions of the channel at the river's mouth. At many ports the tide has changed noticeably after the construction of port facilities, such as breakwaters, etc. In such cases the altered regime of sedimentation and erosion of sand usually plays an important part. Also, sand bars can form and disappear quite rapidly, and a semienclosed lagoon behind such a condition would experience variable tidal "constants."

**Meteorologic Tides.**—The principal meteorologic effects can be ascribed directly or indirectly to variations in atmospheric pressure on the sea surface, tangential stress on the sea surface exerted by the wind, heating and cooling of the sea water.

A varying atmospheric pressure acting on the oceans has the characteristic of a body force, as the pressure gradients are transmitted through the water practically simultaneously from the sea surface to the bottom. For this reason, the dynamical problem is formally equivalent to that concerned with the effect of the tide-generating forces on the oceans, and equations (1) and (2) are still valid provided that  $\zeta$  is replaced by  $-\rho_a/\rho g$ ,  $\rho_a$  being the atmospheric pressure and  $\rho$  the water density.

Under certain circumstances the dynamical response of the ocean to the atmospheric pressure disturbance can become large. If a tidal basin is subjected to a variable atmospheric pressure disturbance acting periodically with a frequency near that of one of the free modes of oscillation of the basin, the amplitude of its response will tend to increase until it is ultimately limited by frictional dissipation. The same is true in the case of a pressure disturbance travelling across the sea surface with the same velocity as that of a long free wave, or  $\sqrt{gk}$ . It may be noted that the depth of the open ocean is so great that storms seldom attain this critical velocity, and so such magnifying effects are more often encountered in shallow seas.

For a longer-period fluctuation the dynamical effects are less important, and under these conditions the ocean's response is similar to that of an inverted barometer. The sea surface is depressed approximately a centimetre for each millibar of pressure increase, and vice versa, according to the hydrostatic law

$$\zeta = -\frac{\rho_a}{\rho g}$$

Pressure changes of 20 millibars occurring in a few days are common at many ports, and so it may be seen that this effect could be one of the principal sources of error in tidal predictions.

Wind blowing across the water surface exerts a horizontal stress on the water directed downwind, largely by virtue of the difference in air pressure on the lee and windward sides of the water waves generated by the same wind. An exact law for this stress as a function of wind speed has not yet been discovered, but the semi-empirical relationship

$$\tau = \gamma \rho_a v^2$$

gives a good approximation. Here  $\tau$  is the wind stress,  $\rho_a$  the density of air,  $v$  the wind speed at an elevation of 15 m. above the water surface and  $\gamma$  is a numerical constant for which the value .0026 gives the best fit to the empirical data.

Wind stress on the sea surface directed toward the coast has the effect of piling up water against the coast, raising the sea level. Longshore winds blowing so that the land lies to the right relative to the wind direction also tend to raise the sea level against the shore (in the northern hemisphere), owing to the effect of the earth's rotation. There are dynamic effects to be considered in both these cases as the wind is seldom so steady that static equilibrium is reached, except in small basins whose period of free

oscillation is quite short.

The effect of the wind stress is enhanced by shoal water for the following reason, based on static considerations. Let us consider the balance of forces in one dimension only, say, the east-west direction. The stress caused by a west wind (blowing eastward) must be balanced by a slope of the sea surface in which its elevation increases eastward. The horizontal pressure gradient associated with this surface slope is essentially constant with depth, so that the greater the water depth the greater is the total force exerted on a vertical water column. Therefore a given surface slope will require greater wind stress to balance it in deeper water than in the shallower water.

Meteorologic disturbances over shallow seas have given rise to disastrous storm surges, such as those that frequently inundate the coasts of the North sea and the Gulf of Mexico. These surges frequently have a roughly periodic character with periods of the order of hours, and under severe conditions their amplitude can attain several metres. The horizontal stress on the water surface due to the wind is usually more important in these surges than the normal force due to the atmospheric pressure disturbance. Such variations of sea level cannot be predicted by the same procedures used to predict the astronomic tide, but considerable success has been obtained in understanding the dynamics of these phenomena, and in a few cases fairly accurate predictions have been made, particularly in the North sea area by a method developed by R. H. Corkan and Proudman. In order to make such a prediction the wind and pressure fields must be known (or estimated with sufficient accuracy) over the water surface of the region and for all necessary instants of time preceding the hour to be predicted.

Variations of water density, caused either by local heating and cooling or by advection of water of different properties, give rise to variations in elevation of the sea surface. If the change in surface level is calculated on the basis that the total water mass in a vertical column remains constant, the hydrostatic law shows that the relative height of the surface is

$$\zeta_s = -\frac{1}{g} \int_{p_a}^{p_b} \alpha dp$$

where  $\alpha$  is the specific volume of the water, and  $p_b$  is the bottom pressure. The quantity  $\zeta_s$  has been called the steric height, and is quite closely related to the dynamic height used in dynamical oceanography. Changes of the order of 10 cm. taking place from one month to the next are common in the ocean. In the seasonal variation of sea level the changes of density of the water are much more important than the long-period tidal constituents.

### MISCELLANEOUS TIDAL PROBLEMS

**Tidal Friction.**—The effect of dissipation of the ocean tide by friction has so far been left out of the discussion, but it is known to be an important factor. Harold Jeffreys has calculated that if the tide-generating forces of the moon and sun could be suddenly turned off, half the tidal energy in the earth's oceans would be dissipated in approximately a day. This dissipation is known to occur practically entirely by the friction of tidal currents against the bottom of a few shallow seas of the earth, and against the long shorelines of the continents and islands. It is a curious fact that probably half of the entire tidal dissipation of energy in the ocean takes place in the shallow Bering sea. This rapid rate of energy dissipation should have a considerable effect on the tides of the world.

The matter of tidal friction is of considerable importance in the motions of the planets and their satellites because it provides a mechanism whereby angular momentum is transferred from one type of motion to another. The tidal protuberance created on the primary by the tide-generating force of one of its satellites is not symmetrical with respect to the line joining their centres, and the satellite's own gravitational attraction on this protuberance exerts a torque on the primary. It can be shown in general that if there were no tidal dissipation, there would be no such torque, and that if the angular speed of the planet's rotation is faster than that of

the revolution of its satellite about it, then this torque always tends to decelerate the planet's rotation. In such a case, the gravitational force of the primary on its satellite deviates slightly from the direction toward the primary's centre of gravity, and tends to accelerate the revolution of the satellite about its primary, provided this revolution has the same sense as the rotation of the primary about its axis. Then, the distance between the primary and its satellite will increase as the satellite's speed of revolution is increased, according to Kepler's laws. The above-stated conditions apply, of course, in the case of the earth-moon system.

The same deductions can be arrived at by an alternative point of view: the frictional force of the tidal currents on the sea bottom and coasts must itself exert a decelerating torque on the earth. If the tidal currents were known accurately enough over all critical regions where the bulk of the tidal dissipation takes place, the decelerating torque could be calculated, since it is known that by far the greater part of the tidal dissipation occurs in the oceans and only a negligible amount in the lithosphere. Actually, the form of the tide over the vast regions of the oceans is so poorly known that neither the gravitational torque method nor the frictional torque method can be applied quantitatively, and it is through records of ancient eclipses and modern observations on the moon's position that the average rate of lengthening of the day and lunar period of revolution have been estimated. It should be remarked that the lunar effect on the earth's rotation should be about three to five times as large as the solar effect.

There are four principal effects: (1) tides raised in the satellites by their primaries will tend to make each keep the same face toward its primary (as the moon presently faces the earth); (2) tides raised in the primaries by the satellites will alter the rates of rotation of the primaries; (3) tides raised in the primaries by the satellites will alter the distances between them; and (4) solar tides will affect all the rotations.

On the basis of the above considerations it has been deduced that during previous ages the earth had a much shorter day and much shorter month (period of lunar revolution), and that the moon was much closer to earth. The day has probably lengthened by a second in the last 120,000 years.

**Internal Tides in the Ocean.**—It has been shown that the tidal current would be uniform from top to bottom at any given locality and instant provided that the sea water had uniform density throughout the oceans. In the actual case, however, variations in the salinity and temperature lead to both time and space variations in the density, and it is possible that this condition would lead to a vertical shear in the tidal current. In any case, there is no reason to believe that there should not exist tidal variations in the water density at any given point in the ocean, and there is evidence on several occasions that such tidal variations may have been actually observed.

The outstanding feature of the density structure of the ocean is that the lighter water is found in the upper layers of the ocean, and in a large number of dynamical problems the ocean can be treated successfully as though the water were stratified; *i.e.*, as though the water in any horizontal plane were homogeneous. In such a situation there can exist an important class of wave motions in which the maximum amplitude of the vertical displacement of the water particles occurs at some depth beneath the surface. These are called internal waves to contrast them with the more familiar surface waves, for which the vertical displacements of the water particles have their maximum amplitude at the surface. Internal waves are similar in many respects to surface waves, but have some important differences: their speed of propagation is much less than that of a surface wave having the same wave length; and the vertical movement of the water particles (at the level of maximum movement) is a great deal larger than in the case of a surface wave having the same energy. Such waves have been observed by making periodical determinations of the vertical density profile from an anchored ship, and the results of such observations indicate that such internal wave motion is common, and that amplitudes of the order of tens of metres are to be expected. The oscillations are irregular, but frequently there appear to be dominant waves of diurnal or semidiurnal period having

all the characteristics of a tidal variation. In order to prove conclusively the tidal origin of such waves, a considerable series of observations would be necessary, and the difficulties and expense of having a ship remain at the same location for a protracted period of time have prevented this study from being carried out.

### ATMOSPHERIC TIDES

As air, like all other matter, is subject to gravitational influence, there will be tides in the atmosphere possessing many features of similarity with those in the ocean. One of the characteristics of these tides will be a very small oscillatory variation in the atmospheric pressure at any place, and this may be regarded as the superposition of harmonic constituents with the ordinary tidal periods. By the systematic analysis of long series of regular barometric records, the principal lunar semidiurnal constituent  $M_2$  of the barometric variation has been determined for a number of places, and found to have an amplitude of the order of .001 in. The dynamical theory of these tides has been the subject of considerable study. The derivation of the equations is not so simple as for ocean tides, one difficulty being that of taking account of the physical conditions in the upper regions. The equations which have been proposed are of the same general form as those for ocean tides, but the theory is still imperfect. The results of analysis for the  $S_2$  constituent show a much larger oscillation with an amplitude of barometric variation of the order of .03 in. For this constituent, however, it is certain that thermal factors play a larger part than gravitational factors, and the theory is far from complete.

### BODILY TIDES

The solid body of the earth, or lithosphere, suffers periodic deformation because of the tide-generating forces just as do the oceans and atmosphere. These bodily tides manifest themselves in the following ways: (1) a variation of the vertical, or plumb line, with respect to any solid structure imbedded in the earth's crust; and (2) a variation in the acceleration of gravity at any point due to the potential of the displaced matter in the earth's body, quite aside from the variation of gravity directly associated with the tide-generating forces.

The gravest free elastic oscillations of the earth's body as a whole have periods of the order of an hour, which is much less than those of the principal tide-generating forces. Therefore, it is probably correct to assume that the bodily tides will approximate closely to their equilibrium forms, or in other words, that they may be calculated on the principles of statics. Owing to the earth's rigidity, the vertical rise and fall of the earth's solid surface at any position on it is somewhat less than that based on the equilibrium tide. The fractional height of the equilibrium tide attained by this surface vertical displacement is practically independent of geographical location, and is designated by the symbol  $h$ . The potential of the displaced matter is additive to the tide-generating potential, its fractional contribution to the latter at any point on the earth's surface being designated by the symbol  $k$ . As in the case of  $h$ ,  $k$  also is practically independent of geographical location. The numbers  $h$  and  $k$  were introduced by the theoretician in the field of elasticity, A. E. H. Love, and henceforth have been called the Love numbers.

The values of  $h$  and  $k$  depend on the geographical form of the disturbing potential, but it is common usage to consider only those values corresponding to a disturbing potential having the form of a spherical harmonic of the second degree, of which the semidiurnal equilibrium form is an example.

Various types of geophysical observations have been used to evaluate the Love numbers. For instance, it can be shown that the acceleration of the earth's gravity at the surface is altered by the amount

$$-\frac{2g\bar{f}}{a}\left(1 - \frac{3}{2}h + k\right)$$

where  $\bar{f}$  is the equilibrium tidal height at the place under consideration and  $a$  is the radius of the earth. A body of water whose natural period is short compared with the tidal periods will set

itself so that its free surface is one of constant potential. If  $\zeta'$  is the elevation of the water surface at a given position relative to the bottom, it can be shown that  $\zeta' - (1 + k - h)\zeta = \text{const.}$  provided that the total volume of water in the basin remains constant. The yielding of the bottom tends to diminish the apparent tide while the additional potential of the displaced mass in the earth tends to increase it, hence the algebraic signs in the terms of  $h$  and  $k$ .

Thus it is seen that precise measurements of the acceleration of the earth's gravity at a point would give a determination of the quantity  $1 - \frac{3}{2}k + h$  while measurements of the water level in a long sheltered tube, free from winds and other disturbances, would give a determination of the quantity  $1 + k - h$ . This quantity also determines the position of the vertical as can be measured by a plumb line or a special instrument called the horizontal pendulum.

It should also be possible to determine the quantity  $1 + k - h$  by means of observations of the ordinary ocean tide, provided its dynamics were well understood. The long-period tides, especially the lunar fortnightly tide  $M_f$ , have usually been utilized for this purpose. It is generally assumed that the periods of these constituents are very much longer than those of all natural oscillations in the ocean basins, and that the equilibrium law would therefore hold. This assumption is certainly valid in the case of ordinary inertio-gravitational standing wave motion in the oceans, but serious objections have been raised on the basis of the possible existence of geostrophic or planetary wave modes characterized by steady or nearly steady ocean currents. There is a further serious difficulty in isolating the purely astronomical long-period constituents in analysis, and it may well be doubted whether reliable constants for the  $M_f$  constituent have ever yet been obtained from the records of observation. The values of  $h$  and  $k$  determined vary considerably depending on the type of observation used, and for this reason are subject to appreciable error. The value of  $h$  is somewhere in the vicinity of 0.6, and that of  $k$  is near 0.3.

The above discussion of the bodily tide has omitted any reference to the complications introduced by the tides in the ocean. There are two effects: the warping of the earth's crust by the varying load on the ocean floor; and the contribution to the total gravitational potential by the displaced water mass. Generally, these effects are more serious closer to the coast and the greater the tidal range at the coast nearby. For this reason measurements of the bodily tide are usually attempted near the centre of large continents.

If the rigidity and density at all points in the earth's body were exactly known, it should be possible to calculate the Love numbers theoretically without need for recourse to observations. The internal constitution of the earth is not precisely known, but certain hypotheses concerning this internal constitution can be rejected on the basis of results of bodily tide observations. Lord Kelvin used the observed height of the fortnightly tide to show that the earth's rigidity, on the average, is greater than that of steel. See also TIDAL POWER and references under "Tide" in the Index.

**TIDORE** (T̄DOR), a mountainous island of the Moluccas, Indonesia, lies a mile south of Ternate and 7 mi. (11 km.) W of Halmahera. It is nearly circular in shape, with an area of about 45 sq.mi. (118 sq.km.). Pop. (1957 est.), 27,753. The southern part is occupied almost entirely by an extinct volcanic peak (5,676 ft. [1,730 m.]). On the slopes below the 1,000-ft. (300-m.) level, coffee, fruit, and tobacco are cultivated, the soil being very fertile. The northern half consists mostly of hills, though there are a few level strips along the coast. The inhabitants are akin to the Ternatans. They sell fish and cultivate garden produce, and some

of the Tidorese are proficient at the craft of metal working. They are Muslims.

Like Ternate (*q.v.*), Tidore is the seat of an ancient and once powerful sultanate. The Portuguese established themselves there in 1521 and fought the sultan, whose capital they destroyed. Later, the Spaniards, when Portugal had become incorporated with Spain, obtained a hold which they retained until well into the 17th century, aiding the Tidorese in maintaining their independence in Ceram, Halmahera, and other islands against the sultan of Ternate and the Dutch. The latter, in 1654, conquered the island, but recognized the nominal power of the sultan. Japan occupied Tidore in 1942. After World War II it passed with the Moluccas to Indonesia. See also *MOLUCCAS*. (E. E. L.; J. O. M. B.)

**TIECK, (JOHANN) LUDWIG** (1773–1853), German writer and critic, the most versatile and productive of the early Romantics. He was a born storyteller, and his best work has the quality of a *Märchen* (fairy tale) which appeals to the emotions rather than the intellect.

Born in Berlin on May 31, 1773, the son of a craftsman, he was educated at the Berlin *Gymnasium* (1782–92) and at the universities of Halle, Göttingen, and Erlangen (1792–94). He came into early contact with literary Berlin through the court composer J. F. Reichardt (1752–1814), but it was through friendship with W. H. Wackenroder (*q.v.*) that he began to realize his talent. Together they studied Shakespeare, Elizabethan drama, Middle High German literature, and medieval town architecture.

In 1794 Tieck returned to Berlin, where he worked on a collection of light stories, *Straussfedern*, which J. K. A. Musäus (*q.v.*) had started. More important, and characteristic of early German Romanticism, are *Die Geschichte des Herrn William Lovell* (three volumes, 1795–96), a novel in letter-form which describes the moral self-destruction of a sensitive young intellectual; *Karl von Berneck* (published in *Volksmärchen*, 1797), a five-act tragedy set in the age of chivalry; and *Franz Sternbalds Wanderungen* (two volumes, 1798), a novel of artist life in the late Middle Ages which shows the influence (and collaboration) of Wackenroder. At the same time he launched a parodistic attack on the Berlin Enlightenment in a series of plays based on fairy tales; they include *Ritter Blaubart* ("Bluebeard") and *Der gestiefelte Kater* ("Puss in Boots"), both published under the pseudonym of Peter Leberecht in *Volksmärchen* (three volumes, 1797), a collection of fairy tales based on old *Volksbücher* (chapbooks). This collection, which includes one of Tieck's best *Novellen*, *Der blonde Eckbert* ("Fair Eckbert"; translated in 1827 by Thomas Carlyle), the fantastic story of an obsessive fear, won him the admiration of the brothers Schlegel, the leading critics of the Jena Romantics, and in 1799 he moved to Jena at their invitation.

In that year he also issued Wackenroder's posthumous papers, published a translation of *The Tempest*, with an essay on "das Wunderbare" (the wonderful, or supernatural), and started a translation of *Don Quixote* (1799–1801). The climax of his early work is the grotesque, lyrical plays *Leben und Tod der heiligen Genoveva* (1800) and *Kaiser Octavianus* (1804), in which the theories of the Schlegels were partly realized. *Phantasia* (three volumes, 1812–16), a heterogeneous collection of earlier works in a narrative framework, indicates a movement toward realism.

From 1802, when not traveling, Tieck lived on a friend's estate near Frankfurt an der Oder. During this period his creative powers were apparently paralyzed. He studied Middle High German, collected and translated Elizabethan plays (*Altenglisches Theater*, two volumes, 1811), and published new editions of 16th- and 17th-century German plays (*Altdeutsches Theater*, two volumes, 1817). He acted as adviser to the great Shakespeare translation begun by A. W. Schlegel (*q.v.*). He also published contemporary German works, supervising the first editions of Novalis (1802), Friedrich ("Maler") Müller (1811; 1825), Heinrich von Kleist (1821; 1826), and J. M. R. Lenz (1828).

In 1819 he went to Dresden, where he was appointed *Dramaturg* (adviser and critic) at the theatre (1825–42). He became the greatest living literary authority in Germany after Goethe. The Dresden period marks a new epoch in his creativity. As a narrative writer he turned away from the fantasy of his earlier work,

introducing more action and taking his material from contemporary middle-class society, or from history. The 40 *Novellen* of this period—including *Der Aufruhr in den Cevennen* (1826; *The Rebellion in the Cevennes*, 1845), *Der junge Tischlermeister* (1836), and *Des Lebens Überfluss* (1839)—contain polemics against both the younger Romantics and the contemporary "Young Germany." *Dichterleben* (part 1, 1826; part 2, 1831) is a *Novelle* about the early life of Shakespeare. *Vittoria Accorombona* (1840; *The Roman Matron*, 1845) is a historical novel. In 1842 he accepted an invitation from Frederick William IV of Prussia to go to Berlin, and there, as in Dresden, he became the centre of literary society by virtue of his masterly skill as a reader and reciter. He died in Berlin on April 28, 1853.

**TIELE, CORNELIS PETRUS** (1830–1902), Dutch theologian and scholar, whose influence on the study of comparative religion, which in his time was only beginning, was very great. He was born at Leiden on Dec. 16, 1830, and was educated at Amsterdam High School and afterward at the seminary of the Remonstrant Brotherhood. He served as pastor at Moordrecht and Rotterdam, then as professor at the Remonstrant Seminary. In 1877 followed his appointment at the University of Leiden as professor of the history of religions, a chair that was specially created for him and that he occupied for 24 years. He died on Jan. 11, 1902.

Among the best known of Tiele's numerous learned works are *Outlines of the History of Religion* (1876; English translation 1877) and his Gifford lectures, published as *The Elements of the Science of Religion* (1897–99). He was also the author of the article "Religions" in the 9th edition of *Encyclopædia Britannica*.

See S. Cramer in *Realencyklopädie für protestantische Theologie und Kirche*, 3rd ed., vol. xix, pp. 766–775 (1905).

**TIEN SHAN** (Russian TYAN'-SHAN; Chinese T'YEN SHAN, "celestial mountains"), one of the great mountain systems of central Asia. Situated in the Soviet Union and China, the Tien Shan is about 1,500 mi. (2,500 km.) long, trending generally west-southwest to east-northeast. The system is located between latitudes 40° and 44° N and extends from the Samarkand area (67° E) in the west to the Kansu border (96° E) of China in the east. There is no general agreement as to its northern and southern boundaries. In the north, the Dzhungarskiy (Dzungarian) Alatau is sometimes regarded as part of the Tien Shan because it is linked to the system by the Borokhoro (Boro Höro Uula) Range (see *ALA-TAU*). Others regard the Dzhungarskiy Alatau as an independent range, with the Ili valley as the northern border of the Tien Shan. In the southwest, the Turkistan, Zeravshan, and Alay ranges are sometimes included in the Tien Shan because of geologic similarities. But on the basis of orographic and tectonic data, these ranges are excluded and the Fergana valley is regarded as the southwestern boundary of the system.

The Khan-Tengri (22,949 ft. [6,995 m.]), situated in a mountain knot on the Soviet-Chinese border, was long regarded as the highest peak of the Tien Shan system. In 1943, however, a Soviet expedition discovered a peak with an elevation of 24,406 ft. (7,439 m.), 13 mi. S of Khan-Tengri, and named the new summit Pobeda (Victory) Peak in honour of Red Army victories in World War II. From the mountain hub, subranges extend toward the west into the Soviet section of the Tien Shan system, and toward the east into the Chinese section.

**Western Tien Shan.**—The western, or Soviet, section of the Tien Shan is complex in structure. It consists of a number of

branches and subranges fanning out from the mountain hub of Khan-Tengri and Pobeda Peak. The northern branch includes the Kungey-Alatau, which encloses the large mountain lake Issyk-Kul' on the north. Parallel to the Kungey Alatau in the north is the Trans-Ili (Zaili) Alatau, rising to 16,243 ft. (4,951 m.) in Talgar Peak. The Trans-Ili Alatau continues westward in the Chu-Ili Mountains, while the Kungey Alatau extends on into the Kirgiz Range. The central branch fanning out from the mountain hub consists of the Terskey Alatau, which encloses the Issyk-Kul' basin on the south. The southwestern branch is made up by the Kokshaal-Tau. These major branches of the western Tien Shan are tall, snow-clad ranges of an alpine character. In sharp contrast is the section bordered in the north by the Terskey Alatau and in the south by the Kokshaal-Tau, where mountain ranges were eroded and converted into peculiar flat-topped summits known as *syrts*. These *syrts* are separated by broad valleys or tectonic depressions. While the outer alpine ranges rise abruptly for 10,000 ft. or more above the adjoining lowlands, the relative elevation of the *syrts* above the intervening valleys is only about 2,000–3,000 ft.

**Eastern Tien Shan.**—The eastern, or Chinese, section of the Tien Shan consists of two parallel series of subranges. The main southern series, extending eastward from the Khan-Tengri Mountain hub, consists of the Khaliq-Tau (12,920 ft.) and the Boro Hatan (11,975 ft.) and terminates at the lake basin of Baghrash Köl.

The northern series of subranges includes the Borokhoro, the Bogdo Uula (17,946 ft.), the Bar Köl Tagh Range (14,094 ft.), and the Karlik Tagh (16,158 ft.). South of the Bogdo Uula lies the Turfan depression, whose salt-marsh-covered floor lies at 505 ft. (154 m.) below sea level, the lowest point in China. The eastern Tien Shan, which divides China's Sinkiang Uigur Autonomous Region into Dzungaria (north) and the Tarim basin (south), is characterized by an echelonlike arrangement of subranges and broad intermontane valleys and basins.

**Geology.**—The mountains of the Tien Shan are made up of sedimentary, metamorphic and igneous rocks of Paleozoic and Precambrian age. The most common rocks are schists, sandstone, limestone, marble, gneisses, granites, and syenite-porphyrates. The intermontane basins, on the other hand, are filled with unconsolidated continental sediments of Tertiary and Quaternary age. The northern ranges were originally uplifted during the so-called Caledonian revolution in the Lower Paleozoic period, while the southern ranges arose during the Hercynian revolution of the Upper Paleozoic. These initial ranges were gradually eroded and converted into a peneplain by the Mesozoic and Tertiary eras. Toward the end of the Tertiary and early in the Quaternary, new uplifts took place to give the mountain ranges of the Tien Shan their present appearance. Downwarping associated with the uplifts produced intermontane valleys and basins. In the process of erosion of the mountains, these depressions became partly filled with eroded material.

**Climate.**—The climate of the Tien Shan is determined largely by its location in the interior of the Eurasian continent among arid desert lowlands of the middle latitudes. The climate of the region is sharply continental, but local contrasts in precipitation and temperatures are due to the great elevation of the Tien Shan and its complex relief. The piedmont plain and the foothills of the system have typically the same desert climate as the adjoining lowlands.

Westerly Atlantic air masses carry the greater part of the precipitation received by the Tien Shan system, discharging it mainly on the west-facing slopes at middle and high altitudes. Annual precipitation on these slopes reaches more than 30 in. (762 mm.) On east-facing slopes and in intermontane basins, annual precipitation is only about 10 in. (254 mm.). Precipitation reaches a maximum in the summer. In keeping with heavier precipitation on the western slopes, these slopes and westward-facing valleys have a heavier snow cover in winter, reaching almost 10 ft. (3 m.). The east-facing slopes and intermontane valleys have virtually no snow in winter. In general the snow line is much higher in the Tien Shan than it is in the European Alps or the western

Caucasus. Even some passes of 13,000 ft. or more are known to be snow-free in summer. Average temperatures vary with elevation. In the valleys and on low-elevation slopes the July average is 21°–24° C (70°–75° F), on medium-elevation slopes 13°–16° (55°–60°) and on the mountain peaks near freezing. The large lake basin of the Issyk-Kul' exerts a moderating influence on temperatures of nearby areas.

**Glaciation.**—The general trend of the mountain ranges of the Tien Shan is east-west, although some short ranges are also oriented north-south. Characteristic features of the Tien Shan are the so-called mountain knots from which short ranges fan out in several directions. Relatively humid air coming from the west condenses on the west-facing slopes of the north-south ranges and the mountain knots, giving rise to valley glaciers. The principal glaciation centres are therefore the Khan-Tengri and Pobeda knot and the short north-south range of Akshiyarak. In the larger mountain knots, glaciers cover a total area of 10,000 sq.mi. The largest ones are the southern Inylchek glacier (35 mi. long), on the southern side of the Khan-Tengri; the northern Inylchek glacier (22 mi. long) on the northern side; and the 13-mi.-long Semenov glacier descending from Semenov Peak (19,081 ft.), northwest of Khan-Tengri.

The Petrov glacier, on the west slopes of the Akshiyarak Range, is 11 mi. long. In addition to the valley glaciers, glaciation is also in evidence on some of the flat-topped summits of the western Tien Shan, where peculiar ice shields are formed on the summits.

**Hydrography.**—The Tien Shan is mainly a region of interior drainage, whose rivers flow either into the desert lakes of central Asia or into mountain lakes without outlet to the sea. Most of the western Tien Shan is drained by the Syr-Dar'ya (*q.v.*), one of the great streams of central Asia, which flows to the Aral Sea. The principal rivers on the northern side of the Tien Shan are the Chu, which disappears in the desert west of Balkhash Lake, and the Ili (*q.v.*), which flows to that lake. On the southeastern side of the Tien Shan, the drainage pattern is dominated by the Tarim (*q.v.*), which also disappears in the desert sands near Lop Nor (*q.v.*) Lake. The river valleys of the Tien Shan tend to be broad except when they cut through transverse ranges. Rising generally at high elevations, the rivers of the Tien Shan are fed by glaciers and reach their high water stage in the summer, when they are most useful for the irrigation of crop lands in the piedmont plains. Some of the smaller rivers rising at lower elevations are fed by ground water, snow and rain. Several of the rivers are used to generate hydroelectric power, notably the Chirchik, a tributary of the Syr-Dar'ya; the Syr-Dar'ya itself; and the Chu river. The Issyk-Kul', largest of the mountain lakes in the Tien Shan, occupies a broad tectonic depression.

**Vegetation.**—The vegetation of the Tien Shan follows a vertical zonation. The lower foothills are covered with desert vegetation, which dries up about mid-May. Irrigated cotton and fruit trees dominate among the cultivated crops. At somewhat higher elevation, above 1,200 ft., an increase in precipitation assures a semidesert vegetation, such as wheat grass, which lasts until the end of June and can be used as spring and summer pastures.

Above the semidesert belt of the foothills lies the dry mountain steppe of feather grass and fescue, which serves as summer and fall pasture and for the cultivation of dry grains. At an elevation of 4,000 ft. begins the grassy steppe with bushes and patches of deciduous trees (walnut, apple, maple). This is a main area of unirrigated agriculture, used for hay and grains. The next higher zone of subalpine meadows also contains coniferous forests of spruce and fir as well as juniper groves. These meadows, which reach up to the snow line, are the principal summer pastures of the Tien Shan region.

**Minerals.**—Outflows associated with Hercynian magmatism have produced some highly mineralized areas in the Tien Shan, notably in nonferrous and rare metals. Among the most important Soviet mineral sites are the copper and lead-zinc ores of Almalyk of the Uzbek Soviet Socialist Republic, the antimony and mercury mines of Khaydarken in Kirgiz S.S.R. and the

tungsten site of Chorukh-Dayron in the Tadzhik S.S.R. Jurassic coal of low caloric value is mined at Angren (Uzbek S.S.R.) and on the periphery of the Fergana valley at Kyzylkiya, Tashkumyr, Kok-Yangak, and Sulyukta. The accumulation of sediments in the Fergana valley has also produced deposits of petroleum, natural gas, sulfur and ozocerite. Geologic exploration is still in its infancy in the Chinese portion of the Tien Shan, but oil fields are already in operation at Tushantze and Karamai in the northern foothills and several sites of nonferrous and rare metals are known.

**Settlement and Transportation.**—The heaviest population concentrations in the Tien Shan are found in the Tashkent (*q.v.*) oasis, the Fergana valley and the Chu valley of the Soviet Union, and in oases at the north foot (Urumchi) and south foot (Kashgar, Aqsu) of the eastern Tien Shan in China's Sinkiang (*q.v.*). The lower valleys and foothills of the Tien Shan, where irrigated agriculture (mainly cotton) is practised, were invaded by indigenous central Asian cultivators, such as the Uzbeks in the Tashkent and Fergana areas of the Soviet Union and the Uighurs in the oases at the southern foot of the mountain system in China. Among the pastoral peoples of the mountains are the Kirgiz in the western Tien Shan and the Kazakhs and Mongols in the eastern Tien Shan.

The population centres of the Soviet portion of the Tien Shan are reached by branches of the Soviet rail system, extending from Tashkent into the Fergana valley and through Frunze (*q.v.*) into the Chu valley and to Rybachye on the Issyk-Kul'. A central Asian railroad linking China and the Soviet Union, completed in 1960, runs along the northern foot of the eastern Tien Shan and through the Dzungarian Gate, a natural passage way at the eastern end of the Dzhungarskiy Alatau. The higher valleys of the Tien Shan are served by roads, many of which can be used by motor vehicles.

(T. Sp.)

**TIENTSIN (T'ien-ching)**, an industrial and commercial city in the province of Hopeh, China, 70 mi. (113 km.) SE of Peking. Pop. (1957 est.) 3,220,000. The city is situated at the confluence of several streams on the lower coastal plain, 32 mi. (51 km.) by river from the Yellow Sea. Until 1782 the place was only a garrison town, but it became a treaty port in 1860, and began to grow rapidly. A foreign settlement was located downstream on the right bank of the Hai Ho. After the Boxer uprising (1900) the walls were razed, and the city was rebuilt on occidental lines. Originally covering only a small area, the former foreign concessions were integrated and the limits have since expanded steadily. The port area of Ta-ku and T'ang-ku was included within the city limits in 1949, and the area along the Hai Ho was annexed in 1953 to make the total area of the city 888 sq.mi. Until 1958 Tientsin was an independent municipality administered directly by the government in Peking; at that time it became a part of the province of Hopeh and also the provincial capital.

Subject to flooding by the six small rivers coming together just west of the city, the main river below the city has long been shallow and subject to silting. The Communists have maintained the earlier pattern of dredging the river, and have built a bypass flood canal around the city on the south side to relieve flood pressures. Though dredging can keep the river navigable for small ships, a new artificial port, Sinkang, able to take 10,000-ton ships at all times, was created at T'ang-ku. This is kept open for about two months during winter by icebreakers.

Tientsin is a leading seaport of China and a rail, an air traffic, and a regional trade centre. Its industrial beginnings predate 1900, but it remained for some decades a centre of such light manufacturing as matches, bicycles, cotton and wool textiles, grain milling, tobacco manufacturing, and simple chemicals. Gradually its variety of industry broadened as assembly operations, heavy machinery, iron and steel and the fuller range of chemical manufactures were added. Under the Communists its importance increased as heavy manufacturing industries were located in newer industrial areas toward the coast. In the mid-1950s marked expansion took place in iron and steel, and in heavy manufacturing. By the 1960s Tientsin was the leading chemical manufacturing centre of China, and had become the third ranking industrial region, behind only Shanghai and the central Liaoning province re-

gion of southern Manchuria. It is the seat of Nankai University. (J. E. SR.)

**TIEPOLO**, the name of a family of Venetian painters comprising Giovanni Battista, by far the most important, and his two sons Giovanni Domenico and Lorenzo.

**GIOVANNI BATTISTA TIEPOLO** (1696–1770), the greatest Venetian painter of the 18th century, was born on March 5, 1696, in Venice, the son of a merchant. He first studied painting under Gregorio Lazzarini, but quickly came under the influence of F. Bencovich and G. B. Piazzetta. His earliest known work, "The Sacrifice of Isaac" in the church of the Ospedaletto, Venice (1715–16), is sombre and still in the manner of Piazzetta. In 1717 his name first appears on the lists of the guild of Venetian painters, and for the next few years he concentrated chiefly on small easel paintings of classical and biblical subjects.

Throughout his life Veronese's was the pervasive influence on Tiepolo's art. The return of G. A. Pellegrini to Venice in 1721 was also crucial for Tiepolo's development, for his work inspired Giambattista to adopt a lighter and gayer palette. These two factors are apparent in his decorations for the Sandi and Dolfin

palaces in Venice (both c. 1725, the latter now dispersed) and in those for the archiepiscopal palace and the cathedral at Udine (1726–27). In 1731 he was called to Milan to decorate the Archinti and Dugnani palaces (destroyed and damaged, respectively, in 1943). In 1732–33 he frescoed the upper parts of the Colleoni chapel, Bergamo. By now he was widely recognized as the leading decorator in Italy. The Swedish envoy Tessin happily characterized Tiepolo's work as "full of spirit . . . of an infinite fire, brilliant colouring and an astonishing speed." Notable among his frescoes in the next 15 years were the ceilings in the Gesuati church, Venice (1737), the Palazzo Clerici, Milan (1740, destroyed 1943), the Scuola dei Carmini, Venice (1740–43), the Villa Cordellina, Montecchio Maggiore (1743), the church of the Scalzi, Venice (1743–44, destroyed 1915), the decorations of the Palazzo Barbarigo, Venice (1744–45, dispersed) and, prob-

ably about 1750, his most admired work in Venice, the scenes from the life of Cleopatra in the great saloon of the Palazzo Labia. He was also producing such masterpieces of oil painting as the huge "Road to Calvary" and its companion paintings the "Flagellation" and the "Crowning With Thorns" for S. Alvise as well as secular and religious paintings for patrons at home and abroad.

In 1750 he was commissioned by the prince-bishop of Würzburg, Ger., to decorate the ceilings of the Kaisersaal and staircase of the new palace with historical and allegorical subjects. These huge frescoes, perhaps his greatest achievements, were completed in 1753. On his return to Venice, his outstanding decorations were the Villa Panigai, Nervesa della Battaglia (1754, now in Berlin), the ceiling of the church of the Pietà, Venice (1754–55), the Villa Contarini, Mira (1756, now in Paris), the Villa Valmarana, Vicenza (1757), the Palazzo Rezzonico, Venice (1758), the Palazzo Canossa, Verona (1761, destroyed 1944) and the Villa Pisani at Strà (1761–62). The huge altarpiece of the "Intercession of St. Thecla" at Este, his most moving religious work, was completed in 1759. In 1761 he was invited to Spain by Charles III and in 1762, accompanied by his sons, he arrived in Madrid where he decorated three rooms in the royal palace (1762–67). He also executed seven altarpieces for S. Pasquale at Aranjuez (1767–69)

and began the decoration of the vault of the apse of S. Ildefonso shortly before his death in Madrid on March 27, 1770.

Tiepolo's work is characterized by his skilled draftsmanship, the high key of his multicoloured palette, his mastery of composition and the extraordinary fertility of his imagination. Besides decorations and altarpieces he painted one or two portraits and a number of *Teste di Fantasia* ("imaginary heads") in the manner of Rembrandt. He produced vast numbers of sketches and finished drawings for collectors, to whom he also supplied numerous freely painted oil sketches—often reductions from larger works. Between about 1740 and 1760 he etched plates distinguished for their imaginative force and brilliance.

In order to achieve his enormous output Tiepolo employed assistants, among whom were Mengozzi-Colonna (for architecture) and his two sons, GIOVANNI DOMENICO TIEPOLO (1727–1804) and LORENZO TIEPOLO (1736–1776). Giandomenico, born in Venice on Aug. 30, 1727, was completely overshadowed by his father as a religious and decorative painter, but he had a real talent for genre painting, especially of scenes from contemporary life and of the popular theatre, such as the decorations of his own villa at Zianigo (1791–93).

Notable among his early works are the "Stations of the Cross" for S. Polo, Venice (1747–49), and the *chinoiserie* decorations of the guest wing of the Villa Valmarana (1757). After his father's death Giandomenico returned to Venice where he executed a number of frescoes and easel paintings, especially of scenes from the *commedia dell'arte*. He, too, produced large numbers of drawings for collectors, besides nearly 200 etchings after his own and his father's designs. He died in Venice on March 3, 1804. Lorenzo, born in Venice on Aug. 8, 1736, seems to have specialized chiefly in genre scenes in pastel. He died in Madrid on Aug. 8, 1776.

**TIERRA DEL FUEGO**, an archipelago lying between 52° 27' and 55° 59' S lat. and 63° 43' and 74° 44' W long. at the southern extremity of South America, and separated from the mainland by the Strait of Magellan. In shape the main island is a triangle with its base on Beagle Channel. The total area is 28,434 sq.mi. (73,643 sq.km.), about two-thirds of which is Chilean and one-third Argentine. The boundary agreed upon in 1881 follows the meridian of 68° 36' 38" W from Cape Espíritu Santo on the Atlantic, and the west-east Beagle Channel. Lennox, Nueva, Picton, and several small islands at the mouth of the channel are disputed between the two republics. The western and southern, Chilean, part is known as the Tierra del Fuego department of Magallanes province, pop. (1960) 6,100; the eastern, Argentine, side is the province of Tierra del Fuego, pop. (1960) 7,955.

**Physical Features.**—The greater part of the main island north of the Almirantazgo Sound-Lake Fagnano depression consists of Tertiary sediments and volcanic material, overlain north of the Inútil-San Sebastián bays depression by glacial material deposited during the Pleistocene ice age. The distribution of land and water and the major relief features in this area are the result of the location of great glacial lakes, the excavation of their overflow channels, and the dumping of great moraines. The Altos del Boquerón, north of Inútil (Useless) Bay, is one such undulating morainic plateau from which drain all the rivers of north Tierra del Fuego. Most of the northern area is, therefore, under 600 ft. (180 m.) in height and the Atlantic and Magellan strait coasts are low-lying.

The southern and western parts of the main island and the archipelago are a great contrast. Cretaceous foothills pass into the southern prolongations of the Andes with crystalline rocks, peaks exceeding 7,000 ft. and mountain glaciers. Mt. Sarmiento (7,333 ft. [2,235 m.]) and Mt. Darwin (7,005 ft. [2,135 m.]) are the highest summits. The western half of the Strait of Magellan,

therefore, is bordered by the precipitous cliffs, rugged coasts and fiords of Desolación, Santa Inés, Clarence, Aracena and Dawson islands. South of the Beagle Channel a similar group of islands, of which Hoste and Navarino are the largest, spread into the waters of Drake Strait and terminate in the headland of Cape Horn, generally regarded as the southernmost point of South America, although the Diego Ramírez group lies 60 mi. to the southwest.

**Climate.**—The climate of Tierra del Fuego is monotonously cool in summer and cold in winter, although average temperatures even in July do not fall below freezing point, and average summer temperatures are below 11° C. (52° F.). Temperature ranges are least in the exposed windy southwestern areas. Rainfall contrasts between western and eastern areas are remarkable. At Bahía Félix on Desolación Island there is an average annual precipitation of 200 in. (5,080 mm.), while at Río Grande in Argentine Tierra del Fuego only one-tenth as much rain falls. The Beagle Channel areas have usually less than 30 in. (762 mm.). Three days out of four are wet in the west; one in four in the east.

**Vegetation.**—In the exposed, precipitous, southern and western areas vegetation is limited to mosses and stunted trees, but where terrain permits, evergreen beech clothes the islands, deter-

E. ALBERT DE LA RUE

AUSTRAL RAIN FOREST OF BEECHLIKE TREES WITH YELLOW HANGING LICHENS ON NAVARINO ISLAND, TIERRA DEL FUEGO

orating upward into bushes, bare rock and ice and snow. The central part of the main island from the Atlantic to Inútil Bay has deciduous beech forests, and the northern plains have a tussock grass cover.

**History and Exploration.**—Tierra del Fuego was discovered by Ferdinand Magellan in 1520 when he sailed through the strait named after him and called this region "land of fire." In 1578 Sir Francis Drake traversed the region. In 1616 Cape Horn (anglicized into Horn) was named by the Dutch navigators Jacques le Maire and Willem Schouten. In 1619 the brothers García and Gonzalo de Nodal first circumnavigated the archipelago. No systematic exploration was attempted until the British admiralry undertook a thorough survey of the whole group by Philip Parker King and Robert Fitzroy during the decade 1826–36. They were accompanied on the voyage of the *Beagle* by Charles Darwin, then a young man. The present place names of the region are due in large measure to these surveys; although Chilean naval exploration and aerial mapping have filled in much detail, most hydrographic charts are based on King and Fitzroy's original work.

For 350 years after Magellan's voyage the region was left in the undisputed occupation of its indigenous peoples, but in the 1880s two events led to its colonization by European immigrants

MAJOR TOWNS AND PHYSICAL FEATURES OF TIERRA DEL FUEGO

and Chilean and Argentine nationals. These were the introduction of sheep farming, which in 20 years spread from Gente Grande Bay to occupy all the grassland areas, and the discovery of gold along the eastern and southeastern coasts and on the beaches of the islands south of Beagle Channel. In the 1890s the gold rush spread to the northern rivers of the main island. The political result of this colonization was the partitioning of the island between Chile and Argentina, Porvenir on the Strait of Magellan becoming the main Chilean town and Ushuaia on Beagle Channel the Argentine capital. The Ushuaia area together with Dawson Island, Río Grande and Lake Fagnano became the main scene of missionary activity among the Indian peoples. Both Chilean and Argentine areas were at first territories administered by the central governments but they were raised to provincial status in 1929 and 1955 respectively.

**The People.**—Ona Indians occupied the pampa and deciduous forest belt of the north of the main island and were hunters of the guanaco and tucu-tucu (similar to a cavy). Yahgan Indians lived in the Fuegian archipelago, especially on Beagle Channel, anchoring their canoes in the dense masses of kelp in those waters and gaining their livelihood from shellfish, seals, and otters. Small groups of Alacalufs penetrated the northwestern channels from the fjords of western Magallanes. Few of these indigenous people now survive, as European settlement of their lands and the ravages of disease spelled their doom.

The present inhabitants of Tierra del Fuego are the immigrants and their descendants who were attracted by the pastoral industry, the gold rush, the discovery of oil, and the general economic expansion of the region. In addition to Chileans and Argentinians, a great variety of European nationalities are represented. Yugoslavs are the predominant element derived from the gold-rush days, with Spaniards, British, and Italians forming smaller minorities. Ushuaia still retains a penal settlement, and a colony of Italians was established nearby in 1948. Most of Tierra del Fuego's people live on the main island, but a subsidiary concentration engages in sheep farming on Navarino Island.

**The Economy.**—Pastoralism and petroleum exploitation dominate the region's occupational and commercial life. Enormous sheep farms were established in the favourable northern areas, one of which still exceeds 1,000,000 ac. (404,700 ha.) in extent, while another carries 185,000 sheep. On the expiry of some of the leases in 1938 and 1957, subdivision of the farms was undertaken

to increase the density of settlement. The discovery of petroleum at Manantiales in 1945 converted the northern part of Chilean Tierra del Fuego into that republic's only oil field; pipelines were laid to the Strait of Magellan for export of the petroleum to central Chile. A small refining plant on the oil field produces the needs of Magallanes province. There is also some lumbering in the forested areas of Beagle Channel and the Strait of Magellan, fish and crayfish canning at Ushuaia and Porvenir, and fur hunting for nutria and seal. A meat refrigerating plant is located at Río Grande but most surplus sheep are processed on the mainland.

Roads are poor, and there are no railways. However, air services link Punta Arenas and Río Gallegos with the principal settlements in the Chilean and Argentine areas, respectively. Sea communications are also important; a regular service plies between Porvenir and Punta Arenas,

and naval vessels supply Navarino and Ushuaia.

**TIFFANY, CHARLES LEWIS** (1812-1902), U.S. jeweler who made a specialty of importing historic gems, jewelry and art works, was born in Killingly, Conn., on Feb. 15, 1812. He moved to New York city in 1837, and with John B. Young opened a fancy goods store. It became Tiffany, Young and Ellis in 1841 and, after branching out into jewelry manufacture, was reorganized as Tiffany & Co. in 1853. Tiffany adopted the standards of English silver in 1851, thereby establishing the term "sterling" in the U.S. and affirming the high prestige of his firm.

In 1858 Tiffany obtained a surplus section of the newly laid Atlantic cable, which he cut into pieces and sold as souvenirs with great success. At the beginning of the Civil War he turned most of his capital to the manufacture of swords, medals and other war material. In 1868 the company was incorporated and branches were established at London and Geneva. In 1887 he bought some of the crown jewels of France. He was made a chevalier of the Legion of Honour in 1878. He died in New York city on Feb. 18, 1902. He was the father of Louis Comfort Tiffany (q.v.).

See F. Heydt, *Charles L. Tiffany* (1893).

**TIFFANY, LOUIS COMFORT** (1848-1933), U.S. painter, craftsman and decorator, who is considered one of the leading original U.S. designers, was born in New York city on Feb. 18, 1848, the son of Charles L. Tiffany (q.v.). He became internationally famous for the inimitable glass which he named favrile, a neologism from the Latin *faber*. Tiffany began experimenting with glass in 1875 and could produce it reliably by the 1890s, when examples were donated to the Smithsonian institution and the Metropolitan Museum of Art; he won a grand prize at the 1900

Paris exhibition. Favrite glass, iridescent and freely shaped, was sometimes combined with bronzelike alloys and other metals; it enjoyed widespread popularity from 1890 to 1915, and again in the 1950s. Trained as a painter of narrative subjects in Paris, Tiffany visited Morocco; eastern and Amerindian influences mark his work. Returning to the U.S., Tiffany became a recognized painter. He established a decorating firm later known as Tiffany Studios, which served wealthy New Yorkers, redecorated the reception rooms at the White House, Washington, D.C., and was most active in church interiors. Stained-glass windows were its specialty, best known being the huge glass curtain (1911) at the Palacio de Bellas Artes in Mexico City. Tiffany, a director of his father's firm, established the Louis Comfort Tiffany foundation for young artists at his luxurious and celebrated Long Island estate (sold in 1946 to provide scholarship funds). He died, Jan. 17, 1933.

**TIFLIS:** see TBILISI.

**TIGELLINUS, OFONIUS** (d. A.D. 69), a Sicilian, who, despite his provincial origin, became one of the chief ministers of the emperor Nero. After being prefect of the *vigiles* (the fire brigade), he became prefect of the praetorian guard on the death of Burrus (q.v.) in 62. Burrus had been sole prefect; Tigellinus shared the office first with Faenius Rufus, who perished for conspiracy in 65, and then with Nymphidius Sabinus. The ancient sources aver that he owed his rise to power to sharing and abetting Nero's vicious pleasures. He took a leading part in the reign of terror that began in 65, but when revolt broke out in 68, he let himself easily be deposed by his colleague, Nymphidius, and did nothing to assist Nero. In 69 the emperor Otho decided to put him to death. He received the order "amid debaucheries and the kisses of his concubines, and after disgusting delays cut his throat with a razor, disgracing his life even in his death, which came too late and dishonourably" (Tacitus, *Histories*, i, 72).

See A. Stein, in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, xvii, 2056-61 (1937). (P. A. Br.)

**TIGER** (*Panthera tigris*), a striped carnivore, the largest of the cat family (Felidae), rivaled only by the lion in strength and ferocity, the difference between them lying mainly in their external appearance. The tiger is confined to Asia, and is widespread south of a line drawn northeastward from the Euphrates, passing the southern shores of the Caspian Sea, the Aral Sea, and Lake Baikal, to the Sea of Okhotsk. It ranges as far south as the islands of Sumatra, Java, and Bali. It is absent, however, from the Tibetan plateau and from the remainder of the Indo-Malay archipelago.

The tiger's characteristic stripes and ground colour vary in distinctness and brightness according to the locality and subspecies. The tigers of Bengal and the islands of southeast Asia, for example, have a ground colour of bright, reddish fawn on the upper and outer parts of the head, body, limbs, and tail; these parts are beautifully marked with dark, almost black, transverse stripes; while the under parts, the inside of the limbs, the cheeks, and a large spot over each eye are nearly white. The tigers of northern China and the U.S.S.R., however, have longer, softer, and lighter-

coloured fur. Rarely, there is a black and white colour scheme. A male may weigh more than 500 lb. (227 kg.), reach a height at the shoulders of 5 ft. (1.5 m.), and a length of 14 ft. (4.3 m.). The tiger has no mane, but in old males the hair on the cheeks is rather long and spreading.

The diet of tigers consists of any animals of the locality; in India, for example, deer, wild hog, and peafowl are common prey. Cattle may sometimes be taken from human habitations. Old or disabled tigers may find human beings an easier prey, and turn "man-eater." Healthy large mammals are generally avoided—the tiger is no match for a water buffalo or an elephant. A pack of wild dogs or dholes can worry a tiger to death. Tigers inhabit grassy and swampy districts and forests; they also haunt ruined buildings. Under stress of fear, they may climb trees. They are good swimmers.

The cubs are born in litters of two to six, three being commonly found; they remain with the mother until they are able to kill prey for themselves, about the second year, when nearly full-grown. In warm regions litters may be produced at any time of the year; in cold districts they are born in spring. Average life span for the tiger is 11 years, but some live to almost twice that age.

Under certain conditions, as in enforced confinement in zoos, tigers occasionally hybridize with lions; the offspring of such matings are called "tigons" when the father is a tiger or "ligers" when the father is a lion.

See Richard Perry, *The World of the Tiger* (1965).

**TIGERFLOWER**, botanically *Tigridia*, a genus of tender herbaceous bulbous plants of the iris family (Iridaceae), natives of Mexico, Central America, Peru, and Chile. They have long narrow leaves springing from the bulb and a stem bearing two or three scattered smaller leaves and above a few flowers emerging from a leaflike spathe. The striking flowers are spotted (whence the name tigerflower, flower of Tigris, or tiger iris) and have free segments springing from a tube; the three large broad outer segments are concavely spreading, the three inner are much smaller and more erect. *T. pavonia*, with large red flowers spotted with yellow and purple, and its many colourful variants are cultivated in gardens.

J. HORACE MCFARLAND CO.

TIGERFLOWER (TIGRIDIA PAVONIA)

**TIGLATH-PILESER** (Akkadian TUKULTI-APAL-ESHARRA) was the name of three Assyrian kings.

TIGLATH-PILESER I (reigned 1116-1076 B.C.) ascended the throne at the time when a horde known as the Mushki (Meshech of the Old Testament) was thrusting into Asia Minor, constituting a serious threat to civilization, as this region was the principal source of iron, then coming into general use. Tiglath-pileser defeated 20,000 Mushki in the Assyrian province of Kummukh (Commagene) and later extended Assyrian control farther into Asia Minor than any of his predecessors had done. He subdued the nomads along the routes to the Mediterranean and reached the Syrian coast, where the Phoenician trading cities paid tribute. Egypt, closely linked by trade with the Syrian coast, made overtures of friendship.

TIGLATH-PILESER II (964-933 B.C.) reigned at a time of which little more is known than that Assyria was beginning to emerge from its collapse of a century before.

TIGLATH-PILESER III (745-727 B.C.) was a great soldier and administrator. Probably a usurper, his original personal name was Pul(u), by which he was still known in Babylonia and in the Old Testament (II Kings 15:19; I Chron. 5:26). At his accession Assyria was in a difficult military and economic plight, and the rapid amelioration of the situation was due largely to Tiglath-pileser's reorganization of the provincial administration.

W. SUSCHITZKY

TIGER (PANTHERA TIGRIS), NATIVE OF ASIA

The following is a probable reconstruction of the events of Tiglath-pileser's reign. His first military activity (745 B.C.) was successfully directed against the Aramaean and Chaldean tribesmen who had brought chaos to Babylonia. In the following year he attacked the lands on the eastern borders of Assyria, creating a new province and securing from the Medes farther east nominal recognition of his suzerainty. With his eastern borders thus secured against Urartu (Armenia), Tiglath-pileser turned to the west to counter Urartian intrigues among the vassal states of Syria. After the defeat of Urartian forces in Kummukh, most Syrian cities formally submitted, though Arpad withstood siege for three years. Tiglath-pileser then (740 B.C.) undertook a campaign to annex Ulubu, the mountainous country north of Assyria.

In 734 B.C. Tiglath-pileser crushed a rebellion in the west which began in the Philistine cities and spread to involve Israel and Damascus; Judah remained loyal to Assyria (II Kings 16:7). In the same year a Chaldean chieftain, Ukin-zer, seized the throne of Babylonia. After a reign of three years he was driven from Babylon by the Assyrian army, which took his tribal capital, Sapia. For the final two years of his reign Tiglath-pileser was king of Babylon in name as well as in fact.

Rost (ed.), *Die Keilschrifttexte Tiglat-Pileasers III* (1893); *Cambridge Ancient History*, vol. iii (1925); H. W. F. Saggs, "The Nimrud Letters, 1952—Part I: The Ukin-zer Rebellion," *Iraq*, vol. xvii (1955). (H. W. F. S.)

**TIGRANES** (DIKRAN), the name of several rulers of Armenia, especially Tigranes the Great (c. 140–c. 55 B.C.), king from 95 or 94. He was the son or nephew of Artavasdes II and a member of the dynasty founded in the early 2nd century by Artaxias. He was given to Mithradates II of Parthia as a hostage and purchased his freedom on Artavasdes' death by ceding 70 valleys bordering on Media.

Tigranes immediately began to enlarge his kingdom. To the west he deposed Artanes, king of Sophene, and annexed his kingdom (east of the upper Euphrates). He entered into alliance with Mithradates (q.v.) VI Eupator of Pontus, whose daughter Cleopatra he married. In 93 he invaded Cappadocia in the interest of Mithradates, expelling the pro-Roman king, Ariobarzanes I, but was driven back by Sulla in 92. Tigranes supported Mithradates during Mithradates' first war with the Romans, although he abstained from interfering openly. Meanwhile he began war with the Parthians, whose empire was weakened after the death of Mithradates II (about 87) by internal dissensions and invasions of the Scythians. Tigranes reconquered the valleys he had ceded and laid waste a great part of Media; the kings of Atropatene (Azerbaijan), Gordyene and Adiabene (both on the upper Tigris), and Osroene became his vassals. He also annexed northern Mesopotamia, and in the Caucasus the kings of Iberia and Albania were subject to him. In 83 he invaded Syria, where the Seleucid dynasty (q.v.) had dwindled to two or three warring pretenders; he defeated these and occupied most of Syria and Cilicia. His rule there was generally peaceful, though Cleopatra Selene, widow of the Seleucid Antiochus X, was still resisting him in 71. In 78–77 he occupied Cappadocia and expelled Ariobarzanes again. Tigranes took the title "king of kings" and built a new royal city, Tigranocerta, on the borders of Armenia and Mesopotamia (the actual site is disputed), where he accumulated all his wealth and to which he transplanted the inhabitants of 12 Greek towns of Cappadocia, Cilicia, and Syria. He also transplanted many Arab tribes into Mesopotamia.

In 72 the Romans drove Mithradates to flee to Armenia, and in 69 Lucullus invaded Armenia. Tigranes was beaten at Tigranocerta (which Lucullus later captured) on Oct. 6, 69, and again near Artaxata in September 68. The recall of Lucullus gave some respite to Mithradates and Tigranes, who even invaded Asia Minor again. But meanwhile a son of Tigranes and Cleopatra, also called Tigranes, rebelled against him; as the old man had already killed two of his sons, he had reason enough to be afraid for his life. The younger Tigranes found refuge with the Parthian king

Phraates III, who sent him back with an army. The old king defeated his son (who fled to Pompey), but then put a price on the head of Mithradates, and when Pompey advanced into Armenia, Tigranes surrendered (66 B.C.). Pompey received him graciously and gave him back his kingdom (for a price), while he treated the son very coolly and soon made him prisoner. The younger Tigranes was led in triumph into Rome; he tried to escape from his confinement by the intrigues of Publius Clodius in 58 and may have been killed in the resulting brawl. The father ruled about ten years longer over Armenia, as a Roman client-king, though he lost all his conquests except Sophene and Gordyene. He died about 55 and was succeeded by his son Artavasdes III.

See R. Grousset, *Histoire de l'Arménie*, pp. 84–100 (1947).

**TIGRÉ**, a province of northern Ethiopia, bordering on Eritrea. Area 25,444 sq.mi. (65,900 sq.km.); pop. (1962 est.) 2,104,100. Its western half comprises high plateau country drained by the right-bank tributaries of the Takkaze River. Vegetation is sparse and cultivation (cereals, legumes) of the better soil areas and stock raising are characteristic occupations. Hides and skins are important export commodities. To the east is the Danakil Desert which includes the salt pan region of Kobar Sink, about 300 ft. (90 m.) below sea level. Makale, the provincial capital, is the centre of the salt trade based on these deposits. It is historically important as the seat of John IV who usurped the Ethiopian throne in 1872 (see ETHIOPIA: *History*). Tigré contains the historic sites of Aksum and Aduwa (q.v.).

Tigrinya is widely spoken. The plateau is largely inhabited by the Tigré (a Semitic group). The Raya and Azebo peoples of the foothills between the plateau and the plain represent an extension of the Galla penetration from the south. The Danakil lowlands to the east are inhabited by Danakil (Afar) nomadic tribes. The Agao (Agaw), in the southwest, represent a survival of the original Hamitic migrations which preceded the founding of the Aksumite Kingdom. (G. C. L.)

**TIGRIS** (Arabic NAHR DIJLAH; Turkish DICLE NEHRİ; biblical HEDDEKIL), a river that originates as several conjoint streams in the tangled hill country of eastern Anatolia north of Diyarbakır, Turkey, being fed by springs and by melt from snow. It then flows generally southeastward for about 1,180 mi. (1,900 km.) toward the Persian Gulf, which it enters as a joint stream, the Shatt al Arab (q.v.), 111 mi. (179 km.) long, with the Euphrates. For 280 mi. (451 km.), as far as Mağara Harabesi (37°08' N, 42°22' E), it is a Turkish river (although before entering Iraq it forms a small 20-mile section of the Syrian border); then for most of its course it lies within Iraq, except for part of the eastern bank of the Shatt al Arab which forms the frontier with Iran for a distance of about 40 mi. from the mouth. The Tigris varies tremendously in width; at the Baghloja Defile 18 mi. below its point of entry into Iraq it is only 40 yd. (36.6 m.) across, and it is even narrower much farther downstream in the region of Al 'Uzayr between Al 'Amarah and Al Qurnah where there are deep gorges. On the other hand, in flatter territory, the Tigris can exceed half a mile in width, and in such areas during the flood season it becomes a vast sheet of water covering many square miles.

The Tigris in Turkey is a typical mountain stream, flowing swiftly in a narrow, well-defined valley often slotted deeply into the surface, with gorges and rapids marking its course. At its entry into Iraq, it begins to cut a somewhat zigzag tortuous course across the ridges and spurs that make up the outlines of the main Taurus and Kurdish mountain systems. There the river alternates between stretches of gorge with clifflike walls, and more open parts with expanses of sand and shingle. Below Mosul the hills continue for some distance, still defining the river valley but declining in height, and there is more open country. Last of these major ridges are the Jabal Khanuqah and Jabal Makhul which are westward extensions of the Jabal Hamrin, and the river breaks through there by the deep gorge of Al Fathah, now used as a crossing point for oil pipelines from Kirkuk to the Mediterranean.

South of Tikrit the valley walls recede, and the Tigris flows for the rest of its course over a wide, gently undulating plain with only a slight, almost imperceptible drop to sea level. Conse-

quently, the river begins to meander extensively, with many loops, dead arms, and cutoffs. A number of former channels once used by the river but now abandoned are either dry or occupied by irrigation works, some of which are extremely ancient. One very extensive former channel may have carried the Tigris well to the east of its present location, as far as Ba'qubah. In order to prevent flooding and further shifting of the river, much embankment is necessary below Samarra'. This is one reason the riverine stretch between Samarra' and Baghdad is relatively empty of towns and large villages, despite the fertility of the area and its intensive use for agriculture. Settlements do occur on older channels or canals at some distance from the main river. Below Baghdad the river follows such an extraordinarily tortuous course that, though the distance by road from Baghdad to Al Kut (Kut al Imara) is about 105 mi. (169 km.), the distance by river is 213 mi. (343 km.) Between Al Kut and Al 'Amarah there are two major valleys that are old courses of the Tigris, the Shatt al Gharraf and the Shatt ad Dujaylah. There, the present channel of the Tigris has been used by the river only since the early 16th century. The topography is now extremely flat, with the river less tortuous but with braided distribution; i.e., channels that disperse water on either side into marshland, or as free-flowing streams into other parts of the valley. On both sides of the river lie extensive marshes, fed by distributaries, which, together with irrigation canals, seepage, and evaporation, diminish the flow of the Tigris by more than 80% during its passage from Baghdad to Al Qurnah. The river consequently shrinks in width, with contractions above and below Al 'Uzayr; its velocity also declines, though the sharp bends and narrowness make navigation difficult. At Al Qurnah the Tigris is joined by the old Euphrates channel to form the Shatt al Arab. There, the Euphrates carries even less water than the Tigris and its flow is almost negligible at certain seasons.

**Tributaries.**—The Tigris is joined by several major affluents throughout its course. The Iraqi Nahr al Khabur (not to be confused with the Syrian Khabur which joins the Euphrates) enters the Tigris from the east, and its lower course forms the frontier between Iraq and Turkey. Though small in length and catchment area, this stream is rapid and carries much sediment eroded from the Kurdistan Hills. Two right-bank affluents, the Wadis Suwaydiyyah and al Murr, enter some distance above Mosul, but the volume of water in both is much smaller.

About 30 mi. (48 km.) below Mosul the Tigris is joined by the Great Zab River (Nahr az Zab al Kabir), which drains a basin of about 7,700 sq.mi. (19,900 sq.km.) in Kurdistan. At low water (September–October), discharge of the Great Zab is 3,000 cu.ft. (84 cu.m.) per sec. and it can be forded; at high water (April–May) the discharge is 28,500 cu.ft. (807 cu.m.) per sec., which adds about 65% more to the Tigris flow. Sixty-five miles below this junction is the point of entry of the Little Zab (Nahr az Zab as Saghir), which drains a basin of 5,750 sq.mi. (14,890 sq.km.). With a minimum flow of 1,340 cu.ft. (38 cu.m.) per sec. in September and a maximum of 16,140 cu.ft. (457 cu.m.) per sec. in March, the Little Zab has an earlier flood because its waters are derived partly from snowfall on lower mountains that hence melts earlier. Above Baghdad the Tigris is joined by the Nahr al 'Uzaym (Shatt al Adhaim) which drains 2,350 sq.mi. (6,087 sq.km.). Because of the low altitude of this basin, melting snow plays little part in the stream flow, which is almost all derived from direct rainfall. In summer the Nahr al 'Uzaym may be almost dry. A more important tributary is the Nahr Diyala (Persian Rud-khaneh-ye Sirvan) which reaches the Tigris on the south side of Baghdad; in summer its flow is diverted for irrigation. Silt carried by the Diyala and deposited close to the Tigris is responsible for blocking many smaller streams and the development of marsh. Farther south, the tributaries are smaller and represent drainage from swamps rather than river flow. One partial exception is the tail of the Karun (*q.v.*), most of which disperses into the Hawr al Hawzah (Hawzah Swamp), with small outlets to the Tigris.

**Regime.**—At the Turkish frontier the Tigris lies at 1,160 ft. (354 m.) above sea level. As it flows south its altitude drops by a gradient of less than one foot per 1,000 as far as Mosul, and then by about 1:2,000 in the Samarra' region. Below Balad, which

could be held to mark the start of real plain, the slope is 1:14,500 as far as Baghdad, and then 1:15,000 downstream as far as Al Kut. Below Al Kut, which is only 39.5 ft. above sea level, the slope is 1:29,000 or even 1:35,000 (about 2 in. per mi.).

At Mosul the average lowest height of the Tigris is 703 ft. (214 m.) above sea level, with a mean discharge of 5,300 cu.ft. (150 cu.m.) per sec. At high water (in April) average discharge is 48,750 cu.ft. (1,380 cu.m.) per sec., producing a rise of about 13 ft., though a rise of more than 16 ft. has been recorded. Comparable figures for Baghdad are: low water (October) 95 ft. (29 m.) above sea level and 11,900 cu.ft. (337 cu.m.) per sec., with a 17½-ft. rise and a discharge of 106,650 cu.ft. (3,020 cu.m.) at the high-water stage in April. Short peak floods of up to 22 ft. are known, and rises measured within 24 hours have been known to exceed 9 ft. At Al Kut the river is only about 40 ft. above sea level, but it normally rises by 16 ft. and may rise more than 20 ft. Of the total discharge at Baghdad, the Tigris itself contributes 45%, the Great Zab 26%, the Little Zab 13%, and the Nahr al 'Uzaym 4%. An additional 22% comes from springs and seepage, and from other water bodies, but there is also an evaporation loss of 6%. Flow is maintained more or less unaltered as far as Al 'Amarah, with evaporation losses balanced by seepage at low water from subsoil drainage. Below Al Kut, however, water is drawn off from the Tigris by natural distributaries and irrigation works, leaving only 19% of the original flow. The fact that the Euphrates lies slightly higher than the Tigris immediately north of Baghdad and lower in the south as far as Al 'Amarah has been used for centuries as a basis for irrigation, with water led by natural flow from one river to the other. Modern systems of irrigation have been developed on the Tigris at Al Kut, where a barrage 21,000 ft. (6,400 m.) in length was completed in 1943. This allows extensive cultivation in the Gharraf and Dujaylah areas, amounting to 750,000 and 230,000 ac. (303,500 and 93,080 ha.), respectively. A weir on the Diyala facilitates irrigation north and east of Baghdad, and construction of a dam on the headwaters of the same river at Darband-i Khan has further extended the irrigated area. Like the high dam built at Dokan on the Little Zab, this barrage stores water at other times than the flood season. Other works allow wider distribution of water; these include barrages at Al Musayyib 40 mi. (64 km.) S of Baghdad, at Butmah (Batma) on the Little Zab, and in the region of 'Uzaym between the Tigris and Little Zab in the Jabal Hamrin area. Other regulators have been projected for the Nahrwan district south of Baghdad, for the Al 'Amarah area, the Shatt al Gharraf, at Ishaqi south of Samarra', and around Irbil, Kirkuk, and Mosul.

The most important control achievement was the completion (1956) of major stages of the Wadi ath Tharthar project. This utilized a vast natural depression between the Tigris and Euphrates as a large reserve drainage basin, water being led in from the Tigris and then partly released at a later period. One considerable benefit achieved was the protection from annual flooding, especially around Baghdad. Seasonal inundation of enormous stretches of territory, together with the cyclical liability to unusually high water, had a restrictive effect on settlements and on lines of communications, which had to be given expensive protection or siting on mounds and levees. It is not always realized that the Tigris because of its spring flooding, when winter crops are well grown, is often a difficult river for agriculture; the Wadi ath Tharthar scheme has greatly improved the situation.

**Navigation and Ports.**—For many centuries the Tigris has been used for transport. The kelek, a raft made of inflated skins and reeds that can carry up to 50 tons, is used when traveling downstream. Small craft, mainly the *quffah* (coracle) and *safinah* (sailing boat), also ply mainly downstream, the latter sometimes transporting 100 tons. The Tigris is navigable by shallow-draft steamers upstream as far as Baghdad. River traffic, however, has tended to decline in recent years because of improved road transport, the completion of standard-gauge railway links north and south from Baghdad, and the fact that navigation is never easy due to the narrows, numerous bends, and shifting shoals and sandbanks.

Chief cities on the Iraqi portion of the Tigris are Baghdad

(*q.v.*; the capital), Basra (*q.v.*; the chief port), which is a conglomeration of several towns along the Shatt al Arab, and Mosul (*q.v.*). On the Shatt al Arab lie the Iranian towns of Abadan and Khorramshahr (*qq.v.*). The former is entirely an oil port concerned with refining and exporting oil and handling supplies for the oilfields; the latter is the principal general port for Iran, handling a large proportion of general Iranian exports and imports other than oil. All these riparian towns are now linked by rail, with the exception of Abadan. (W. B. Fr.)

**History.**—The name of the Tigris River first appears in its Sumerian form *Idigna* in the 3rd millennium B.C. In Babylonian and Assyrian it became *Idiglat*, and in old Persian, *Tigra*, from which was derived the Greek form *Tigres* used by Herodotus (*c.* 450 B.C.).

The Tigris was used by the Sumerians as a source of water for irrigation, and a canal, on the line of the present Shatt al Gharraf (or al Hai), was dug as early as 2400 B.C. to bring its waters to Lagash in eastern Sumer. About 1850 B.C. it was extended to Larsa on the Euphrates. No ancient cities have been discovered along the main course of the river, the Shatt al 'Amarah, either because its regime was less suitable for primitive irrigation or because the area was more open to attack from the east. There is consequently no evidence for minor variations in its position. The mouth of the Tigris has not, in historic times, lain appreciably to the north of the present gulf shoreline and only one major change in its course can be traced when, after the formation of the Great Swamp caused by catastrophic floods in the 6th and 7th centuries, the river deserted the Shatt al 'Amarah and flowed into the marshes by the Shatt al Gharraf. The Omayyad city of Wasit was founded astride the new channel in A.D. 703 and remained important until the 15th century, when the river gradually reverted to its former course. The river plain of the middle Tigris was intensively cultivated by irrigation from early times until about A.D. 900.

Most of the canals west of the river flowed from the Euphrates into the Tigris. On the east all canals, and probably many sites, earlier than the Hellenistic period are buried under a thick silt deposit, but at least as early as Sasanian times (about A.D. 250) the eastern plain was served by a great canal, the *Nahr Nabrawan*, which left the Tigris below Tikrit and rejoined it near Al Kut, receiving en route the waters of the al 'Uzaym and Diyala rivers. After the fall of the Achaemenid Empire (330 B.C.), this wealthy region became the political and commercial centre of Mesopotamia; Seleucia and Ctesiphon (*qq.v.*), respectively the royal cities of the Seleucid and of the Parthian and Sasanian dynasties, and Baghdad and Samarra, both Abbasid capitals, all lay on the Tigris. The Tigris floods, which occur annually from April to May, have often caused destructive inundations in the plain and threatened the safety of Baghdad, particularly since the breakdown of the irrigation systems in the 14th century A.D. This threat has been met by the Wadi ath Tharthar control project (see *Regime* above).

The rolling terrain north of Tikrit formed, from the early 2nd millennium to 612 B.C., the kingdom of Assyria, with its capitals at Ashur, Nimrud (Kalakh), and Nineveh (*qq.v.*) on the Tigris. There irrigation was confined to small areas near Kalakh and Nineveh. Water transport by rafts of a type still used dates back at least to Assyrian times, but the great military and commercial routes were usually in open country away from the river. Shalmaneser III (859–824 B.C.) set up his statue at the sources of the Tigris, but in general neither Assyrian annals nor the later accounts of Greek and Roman writers provide much precise information about the geography of the river valley. From A.D. 197 to 237 the Tigris north of Mosul formed the boundary between Roman Mesopotamia and Parthian Adiabene, and the fortress city of Amida (Diyarbakir) figures frequently in late Roman and medieval chronicles. Mosul, with its boat bridge, became a commercial centre in Abbasid times, and during the 12th and 13th centuries was a capital of the Seljuk Atabeg dynasty. The medieval post road from Baghdad followed the east bank of the Tigris, and many Arab geographers describe the settlements along its route.

European travelers occasionally voyaged on the Tigris after the 16th century. J. Newberie went by boat from Baghdad to

Basra in 1581 and is the first to speak of the Shatt al 'Amarah as the navigable channel. In 1652 Jean Baptiste Tavernier traveled by raft from Mosul to Baghdad and then by boat to Basra. The first modern survey was undertaken by the Euphrates expedition under Francis Rawdon Chesney (*q.v.*) in 1836, supplemented by the work of Felix Jones in 1846 and 1848. A steamship service between Basra and Baghdad was inaugurated in 1861, and the river served as the main supply route for the British invasion of Iraq, 1914–18.

**TIKAMGARH**, a town in the Rewa division of Madhya Pradesh, India, and the headquarters of the district of the same name, lies about 50 mi. (80 km.) SSE of Jhansi. Pop. (1961) 20,469. Maharaja Vikramajit selected it as the new capital of Orchha State in 1783. Until 1887 the town was called Tehri. It has a fort and a lake, Bara Sagar, as well as a palace now used as a college.

TIKAMGARH DISTRICT has an area of 1,944 sq. mi. (5,035 sq. km.) and a population (1961) of 455,662. It occupies the central part of the Betwa-Dhasan Doab, presenting a rolling gneissic surface, with artificial lakes at Birsagar, Jatara, Ladhaura, and Baldeogarh. The principal crops are wheat, rice, jowar, and sesamum. There are no industries except handloom textiles. The district has old Jain temples at Papora and Ahaar and a Sun Temple at Marhkhhera. (S. M. A.)

**TIKAR**, a group of West African Negro peoples. The Tikar tribe proper live in a vast plain along the Mbam River east of Fomaban in the Republic of Cameroon. They numbered about 9,000 (1960s), 2,000 more living with the Bamum (*q.v.*). They farm, raise small animals, hunt, and are good craftsmen. Politically they are divided into eight small states: Bankim, Beng-Beng, Ina, We, Yakong, Ngambé, Ngume, and Ditam. Verbal traditions indicate they arose from the Mbam people near what is now the city of Ngaoundéré.

About 300 years ago Tikar offshoots began migrating westward under pressure from the Chamba people to the north, internal dissension, and a desire for new land. They settled on the high grassy Bamenda plateau where more than half of the modern inhabitants (belonging to 30 kingdoms) were counted as Tikar. They are ruled by kings known as Fon (Afon) with the help of queen mothers. Nsaw (*q.v.*, 52,000), Kom (26,000), and Bum (5,000) were strong, consolidated kingdoms prior to European advent. Other Tikar groups include Mbem (17,000), War (13,000), Tang (12,000), Wiya' (10,000), Mbembe (11,000), Misaje (8,000), and Mfumte (6,000). Fungom, including a number of small independent groups, numbered 20,000. Bafut, Babanki, Babanki-Tungaw, Bafreng, Bambili, Bambui, and Bamenda totaled 33,000. Oku, Bamessing, Bamessi, Bamungo, Bafanji, Baba, Bangola, Bambalang, Bamunka, Bamale, Bamum-kumbat and Bali-kumbat in the Ndop (Ndob) area totaled 34,000. Groups such as the Bamum also acknowledge Tikar origin. Almost all these groups are patrilineal (the Kom and five Fungom villages are matrilineal).

Most Tikar groups (and those influenced by the Tikar) have windowless, square, wattle-and-daub houses, each with a pyramidal thatched roof, and an entrance closed by a sliding door of raffia poles. House posts and door frames are often elaborately carved. The notable Tikar art declined following European contact. They produced beautifully carved wooden stools, bedposts, figures, masks, bowls, and drums, and carved ivory tusks and drinking horns. Smoking pipes of clay were modeled in human form. Beaded calabashes, bottles, stools, figures, and fly whisks were made. Cotton was woven and dyed in resist patterns, while raffia mats and bags were decorated with human, faunal, and geometric designs. Bells, bracelets, pipes, small figures, and large masks were delicately cast in brass (lost-wax process), particularly at Fomaban, the Bamum capital. (W. L. B.)

**TIKHON** (VASILI BELAVIN) (1866–1925), the first patriarch of Moscow (1917–25) after patriarchal leadership of the Russian Orthodox Church was restored under Soviet government, was born in 1866 near Pskov. Before his election as patriarch in 1917,

Tikhon was, among other things, bishop to the Orthodox in North America. During this period (1903–04) his extreme demands contributed to the collapse of negotiations on intercommunion with the Protestant Episcopal Church. From 1913 he was archbishop of Vilna.

When the Soviets came to power, their first steps included the nationalization of church land, the taking over of all schools and seminaries, the establishment of exclusively civil marriage, and the withdrawal of all subsidies to the church. Under Tikhon's leadership the anathema was pronounced (Jan. 19, 1918) by the All-Russian Regional Council on "all who take part in acts of robbery against God"; i.e., practically speaking, on the Soviet government and its adherents. Under the law of Jan. 23, 1918, church and state were completely separated, and the church was dispossessed and deprived of its rights as a legal person. The way was opened for many local attacks on priests and congregations. The decree of the Central Committee of the Communist Party of Feb. 23, 1922, created a new climax in antichurch action, with the confiscation of all church treasures for the relief of the hungry. It ignored the fact that a few days earlier Tikhon himself had called on his priests to donate all unconsecrated objects of value for this purpose. When the decree came into force, even holy objects were seized, churches were desecrated and plundered, and priests, who resisted in accordance with the canons of the church, were murdered or imprisoned. Tikhon was taken into custody because of his opposition to these deeds of violence. During the civil war of 1918–22, however, he had never made common cause with the "whites" but had always described himself as the father of his "believing and straying children," calling for repentance and prayer. At first he had not released from his jurisdiction the metropolitans and bishops who had emigrated, and he was therefore suspected of anti-Soviet activity.

During his imprisonment, Tikhon considered anew the whole relation of church and state and came to the conclusion, based on Rom. 13:1–6, that the Soviet government was now the divinely sanctioned power in Russia and that the faithful owed it secular obedience. In his famous epistle of June 28, 1923, he condemned all counterrevolutionary action against the government. During the last years of his life, however, he also opposed the division of Russian Orthodoxy through the "Living Church" movement, which aimed at a reform of the church through a mixture of socialist and communist ideals with a colourless Christianity. He died in Moscow on April 8, 1925.

**TILAK, BALGANGADHAR** (1856–1920), Indian political leader, called by Indians *Lokamanya*, "honoured by the people," was born at Ratnagiri (Maharashtra State) on July 23, 1856, of a Maratha family of Chitpavan Brahman caste. Educated at the Deccan College, Poona, he studied law before turning to journalism. He became proprietor and editor of the *Mahratta* and the *Kesari* ("Lion"), in the English and Marathi languages respectively. His use of Marathi was particularly effective, and in the villages people would gather together to have the *Kesari* read to them. He thus became widely known for his bitter criticisms of British rule and also of those moderate nationalists who advocated social reform on Western lines as well as political reform on constitutional lines. He thought that social reform would only divert energy from politics, and he derided the moderates' reliance on speeches and petitions as "political mendicancy." He sought to widen the popularity of the nationalist movement (which at that time was confined largely to the upper classes) by introducing Hindu religious symbolism and by invoking popular traditions of the Maratha struggle against Muslim rule, creating an annual festival honouring Sivaji, the 17th century Maratha hero and bitter enemy of the Mughal government. But if this made the nationalist movement more popular, it also made it more communal and it alarmed the Muslims.

When the Congress Party met at Surat in 1907, Tilak unsuccessfully challenged the moderates for the leadership, after which

he led his extremist group out of the party, not to return until 1916. What was considered to be the inflammatory character of his language led to his conviction for sedition in 1897, after two British officials had been assassinated in Poona, and again in 1908. He spent six years in prison after the second conviction, making use of the time to write his commentary on the Bhagavad Gita, in which he emphasized the value of selfless activity rather than withdrawal from the world. Tilak was one of the first to maintain that Indians should cease to cooperate with foreign rule, but he always denied that he had ever encouraged the use of violence. In 1919 he unsuccessfully sued Sir Valentine Chirol for libel arising out of statements to that effect in the latter's book *Indian Unrest* (1910). By this time he had mellowed sufficiently to oppose M. K. Gandhi's policy of boycotting the elections to the legislative councils established as part of the Montagu-Chelmsford reforms (see MONTAGU, EDWIN SAMUEL), advocating instead "responsive cooperation." He died in Bombay on Aug. 1, 1920. See also INDIA-PAKISTAN, SUBCONTINENT OF: *History*.

**TILBURG**, a town in North Brabant province, the Netherlands, is on the Wilhelmina Canal, in the centre of the Benelux countries, 13 mi. (21 km.) E of Breda. Pop. (1960) 130,818. Tilburg rose to prominence after 1860 as one of the chief industrial (textile, metal, leather) centres of the south; textiles were of prime importance in the mid-1960s. The town was the favourite residence of William II, king of the Netherlands until 1849, whose palace has been restored and adapted as the Town Hall. A Roman Catholic university, a conservatory, an academy of plastic and constructive arts, and a textile school are there. Much of the surrounding area is wooded and scenic.

**TILBURY**, an area in the Thurrock (q.v.) urban district of Essex, Eng., on the north bank of the Thames, opposite Gravesend and about equidistant from London Bridge and the Nore. It is famous for its docks, constructed in 1884–86 and since extended and modernized by the Port of London Authority. The system has a total land area of 725 ac. and a water area of 106 ac. The quays extend over 4 mi. and the principal entrance lock is 1,000 ft. long and 110 ft. wide with a depth on the sills of 45½ ft. The largest of the four dry docks is 750 ft. long and 110 ft. wide. A river cargo jetty, 1,000 by 50 ft., is connected by rail, and the riverside landing stage, 1,142 ft. long, enables the largest ships to embark or disembark passengers at any state of the tide.

No. 1 berth, the passenger terminal in the main dock, and no. 4 shed, the centre of the vehicle ferry service to Antwerp and Rotterdam (for both freight and passenger vehicles), were added to shipowners' accommodation in the mid-1960s. Four new berths were completed in 1965–66, two of which are for roll-on, roll-off traffic; two more were ready by the summer of 1966; five further berths were scheduled for completion by 1967, making a total of 11 new berths from 1965 to 1967. The Dartford-Purfleet Tunnel under the Thames (opened in 1963) and improved approach roads enable much road traffic to reach the docks without passing through Greater London.

**TILDEN, SAMUEL JONES** (1814–1886), governor of New York State and Democratic candidate for president of the United States in the disputed election of 1876, was born at New Lebanon, N.Y., Feb. 9, 1814. His formal education was sporadic; for brief periods he attended Yale College and the University of the City of New York, and studied law. He began to practise law in New York City in 1841. Despite frequent illness, he soon became a leader in Democratic politics and a corporation and railroad lawyer of great skill and ability. He served in 1846 in the New York Assembly and was a member of the state constitutional conventions of 1846 and of 1867. He was a loyal supporter of Van Buren and a leader of the Barnburner or Free Soil element among the New York Democrats. When the Civil War broke out he supported the Union cause but opposed certain policies of the Lincoln administration. He played a prominent role in the reorganization of the Democratic Party in the decade 1865–75, serving as the party chairman for New York State. He was an astute and

resourceful leader in the struggle to overthrow the notorious Tweed Ring in New York City (*see* TWEED, WILLIAM MARCY) and in the removal of several corrupt municipal judges. Elected governor in 1874 on a reform platform, he won national recognition for his accomplishments in exposing the Canal Ring (a conspiracy of politicians and contractors engaged in defrauding the state) and in his efficient administration of state government.

In 1876 he was the Democratic nominee for the presidency. The bitterly fought campaign ended in the disputed election of 1876, when two sets of returns were sent to Washington from Oregon, Florida, Louisiana, and South Carolina. Congress, with a Republican Senate and a Democratic House, created an electoral commission (*q.v.*) to settle the controversy. Tilden reluctantly consented to the formation of the commission but failed to provide vigorous and direct leadership in the crisis. There is some evidence that the Republicans entered into a secret deal with Southern leaders to withdraw Federal troops from the South if the disputed Southern electoral votes could be counted for the Republican candidate, Rutherford B. Hayes. The commission decided all questions by a strictly partisan vote (8 Republicans to 7 Democrats), thus giving the presidency to Hayes. Tilden, although convinced he was the people's choice, accepted the verdict as an alternative to possible violence.

A lucrative law practice and profitable investments brought Tilden great wealth. Personally he was cold, secretive, dilatory, and cautious, but he possessed marked intellectual ability and cultural attainments. He was highly respected as a reformer. His frail health and characteristic indecision forced him into the background of politics after 1877, though he retained great influence in the Democratic Party. He remained a bachelor all his life. He died on Aug. 4, 1886, in New York, leaving the bulk of his estate to be used for establishing a free public library for the city of New York.

**TILDEN, WILLIAM TATEM** (1893–1953), U.S. tennis player, first American to win the men's singles at Wimbledon, dominated tennis in the 1920s. Born in Philadelphia, Feb. 10, 1893, Tilden was 27 when he won his first national championship, in 1920. For 10 straight years he ranked at the top, winning seven national championships—six (1920–25) in a row and the last in 1929. He won the Wimbledon title in 1920, 1921 and 1930, was on 11 Davis cup teams and led the battle that kept the prized cup in the U.S. for seven straight years. He won a total of 70 U.S. and international championships.

Tilden had powerful shoulders, a light frame and long legs—the perfect tennis build; he was famous for his cannonball serve and a paralyzing forehand and backhand. He died in Hollywood, Calif., June 5, 1953.

(J. D. McC.)

**TILE**, a thin, flat slab or block, usually of burned clay, glazed or unglazed, used either structurally or decoratively in building. The usage of the word varies widely; in connection with roofing, flat slabs of any material are sometimes termed tiles, as, for instance, the marble tiles of some Greek temples or the bronze tiles of ancient Rome. Similarly, stone slabs, used for roofing, as in certain parts of England, are termed stone tiles; slate, however, is never so called. Many forms of rough terra cotta used structurally in building are called tiles; thus an arch of hollow terra-cotta blocks between steel beams is known as a tile arch; partitions built of hollow terra-cotta blocks are known as hollow-tile partitions; rough terra-cotta pipes used for drainage are called drain tiles; and the steel forms used for casting certain types of reinforced concrete floors are frequently referred to as steel tiles.

The differentiation between tile, terra cotta (*q.v.*) and brick is thus exceedingly vague. (*See* BRICKWORK.) Modern usage extends the word "tile" to include blocks or panels made of plastics, glass and sound-absorbing materials.

**Roofing Tile.**—There is no evidence of the use of roofing tiles in the Mediterranean basin prior to the development of Hellenic civilization, but the most ancient examples of roof tiles show such highly developed forms that earlier usage must be assumed. The Greek form of temple roof which remained constant throughout

the history of Greek architecture (*q.v.*) consisted of two types of tile, used together. First the roof surface was covered with tiles generally flat, but with adjoining edges raised, laid in overlapping courses, and all of equal size. Convex covering tiles, also overlapping, were then laid over the joints of the flat tiles below; in this manner an absolutely watertight roof could be produced. In order to make the architectural effect more delicate the ends of both lower tile and covering tile were rebated, so that the thickness of the overlapping portion was only half the thickness of the tile. At the bottom of each row of covering tiles was either a marble or tile upright, curved, decorative member known as an antefix.

In some cases the covering tiles were of pointed, straight-line section—the most common Greek type—in others a tile of semi-circular section was used, easy to manufacture but lacking in the extreme refinement of the other type; in the simpler domestic work, the lower courses were also of curved section, a segmental concave shape replacing the flat tile with raised edges. The marble tile used in some Greek temples, as in that of Bassae (5th century B.C., by Ictinus), is universally of the type with flat under tile and pointed covering tile, although at times, in order to reduce the number of joints, the covering tile and the under tile are cut from the same piece of marble.

Two other types of roof tile were common in Roman architecture (*q.v.*) and probably represent common Mediterranean types of much earlier origin. One of these is the so-called "Spanish tile," also called "pantile," with a contour resembling the letter S, in which the convex part of each tile fits over the edge of the concave portion of the next. The other type is the shingle or flat tile found frequently in the Roman ruins of the northern provinces. These flat tiles are often of stone.

The usual material of all of these types of tile is burned clay, varying in colour from orange-yellow to purple-red. It is known, however, that bronze tiles were relatively common on the most monumental buildings of the Roman empire. Due to the rarity and value of bronze during the middle ages and the Renaissance, no examples of ancient bronze roof tiles are known.

All of the classic forms of clay tile continued in use in various parts of the world during the medieval period, but their supremacy as a roofing material gradually yielded to lead and zinc for churches, public buildings, palaces, etc., and to slate, stone and thatch for the smaller private houses.

Clay roof tiles remain of substantially the same form; improvements have been only in methods of manufacture and not in design. The flat tile designed to hook over roof battens or boards is perhaps the most common type of small house-roof covering in England and parts of France, and the combination of concave under tile and convex over tile is almost universal on pitched roofs in Italy, Spain, Greece and Turkey. The S-shaped tile is also common around the Mediterranean. The curved tiles are almost always laid in a heavy bed of waterproofed mortar, with ridges and hips covered by courses of overlapping tiles, similarly bedded; with flat tiles, the use of mortar is restricted to the convex or pointed tiles covering the hips and ridges.

The best modern usage in laying tiles of this type demands the complete covering of the roof surface with a watertight material such as slaters' felt or heavy waterproofed paper before the tile is applied. The tiles themselves are held in place sometimes by copper nails which secure the under tiles direct to the roofing and the covering tiles to wood battens which run up the slope of the roof under each row of covering tiles, and sometimes by copper wire brought up through two holes in each tile and twisted together.

Although various attempts have been made to imitate clay tiles in stamped metal and concrete, these imitations are so lacking in the individual variation typical of ceramicware that their use has been restricted to the cheapest type of jerry-built construction; their use, even there, is seriously questionable. Quite different are the roofing tiles of reinforced and waterproof concrete, which are common in industrial buildings, especially in Europe. These modern, industrial tiles are usually of large size—sometimes running to four feet in length, and arranged to interlock, with the exposed surfaces grooved or channeled in such a way as to lead

the water away from any joints. In these concrete tiles colouring matter is usually added in the material itself. (See also *Roof*.)

**Roofing Tile in the Far East.**—Although the principle of the roofing tiles of China and Japan is the same as that in the west, there are many differences in detail. Thus, in temples and palaces in China, the under tiles are slightly concave and overlap, much like those of classic roofs; the covering tiles, however, are made absolutely cylindrical in general contour, with rebated ends, so that they form long, unbroken lines of shadow down the roof. Moreover, instead of the upright antefix of the classic roof, the Chinese tiles have ornaments that project downward, in generally scalloped shapes, over the face of the cornice. There is also, particularly in north China, a tremendous elaboration of ridge and hip tiles, which are frequently of great height, with an elaborately molded section, carrying at their ends rows of animals—a great dragon or the like. At the ends of the ridge are large, grotesque beasts with their heads pointing inward; all these ornaments are modeled and baked in the tile itself. One of the chief glories of the Chinese roof tiles is their colour. This is produced by a shiny glaze that reveals the expected Chinese ceramic skill. The usual colour of temple and palace roofs is bright yellow, but other colours frequently occur. In central and south China, even temple roofs are frequently black. The cheap roof tile of the ordinary house is also almost black, but without lustre and with overlapping covering tiles like those of the west. (See also *CHINESE ARCHITECTURE*; *TEMPLE ARCHITECTURE*.)

The same pattern of rebated, continuous, cylindrical covering tiles is common in the Buddhist shrines of Japan, but colours are rare, the ordinary tile being gray, with a very effective and artistic silvery lustre. (See also *JAPANESE ARCHITECTURE*.)

**Floor Tile.**—Except as small fragments of tile occur in classic mosaic (*q.v.*) and terrazzo, tile for floors does not seem to have been common in Europe prior to the 12th century. In the late

12th and 13th centuries, however, tile floors became usual in churches and other important buildings. The most common type consisted of square tile in two colours, usually a dark brown-red and a pale orange or brownish yellow. They were made by casting clay in such a manner that the parts to be in a lighter colour were sunk; when dry, these parts were filled with a clay of different composition which would burn to a lighter colour; the tile thus prepared was then burned.

Patterns were formed of many tiles and consisted usually of circles or stars containing heraldic beasts, ecclesiastical symbols, etc.; in many cases the pattern was made with reversed colours, so that what was background colour in one tile was ornament colour in the one next to it.

In the earliest examples designs were formed by a mosaic treatment in which the pattern was made by the shape and size of the individual tiles, as in the 13th century example found at Fountains abbey and at Prior Crauden's chapel at Ely (1321-41), both in England. Other common types of medieval pavement have the pattern merely incised, producing the artistic effect of a sketch.

The development of floor tiles in Gothic France was similar. The 12th-century examples are usually mosaic in type with black, dark green, light green and yellow as the predominating colours. The richest examples of these are in the abbey church of St. Denis, near Paris, where certain elaborate chapel floor pavements still exist from the original building (1140-44) by Abbot Suger. By the end of the century, mosaic had yielded to two-coloured tiles of red and yellow, similar to the English tiles mentioned above. The same type remained constant until well into the 15th century, the designs becoming continuously thinner and more delicate; in the 16th century the art died out, superseded by the painted majolica pavements of the Renaissance.

The Gothic revival of the middle 19th century led, in England,

to the revival of the designing and making of tiles of the medieval type and many modern pavements were placed in old churches as a result. Most of this tile has a simple lead glaze and is made not by casting damp, plastic clay, as in the medieval examples, but by compressing powdered clay in steel dies so that shapes are more perfect and the rapidity of manufacture is vastly increased. This type of tile, usually known as encaustic, is especially associated with the English ceramic works at Stoke-on-Trent, particularly those of Minturn.

Meanwhile the Moorish skill in tilemaking had gradually come to be applied to floors. This type of majolica tile was adopted in early Renaissance churches, both in Italy and Spain, although not many examples remain, as the glaze was too soft. The decoration of the Italian majolica pavements consists of the same type of free and graceful classic arabesque trophies, acanthus ornament and coats of arms that is found on contemporary majolica.

In France not only were Italian tiles imported and used, but there soon grew up a local manufacture of similar painted floor tiles, especially at Rouen (established by Masseot Abaquesne, 1542-57), Nevers and Marseilles. With the increasing use of oak parquet flooring for houses and marble for churches, toward the end of the 17th century, the use of tile diminished. There was similar importation of Italian and Spanish tiles into England during the early Renaissance and possible spasmodic attempts toward the making of certain types of this tile in England itself. In the 18th century the use of plain, undecorated, square, red tiles, now commonly known as quarry tiles, became common all over northern and western Europe, and to a less extent in the American colonies.

The greatest advances in modern floor tiles have been made in simple, vitrified, mosaic tiles for use in bathrooms, kitchens, swimming pools and public corridors. These are always machine-pressed and are made of fine clays, thoroughly vitrified and very hard. These are made in small squares, rectangles, hexagons and circles, in a few simple colours. Some, by the addition of gritty substances, such as alundum or carborundum, are given a surface which prevents slipping, even when the tile is wet.

**Wall Tile.**—Earthenware was used spasmodically for wall decoration by the Egyptians, as in the doorway of the Abusir pyramid of Neterkhet (3rd dynasty). More usually, however, they were in the form of mosaic (*q.v.*). Perhaps based upon earlier Egyptian examples, the people of Crete (*q.v.*) developed to an even higher degree the use of faïence for walls. Thus our knowledge of early Cretan houses is largely furnished by many fragments of small faïence plaques from the 18th century, B.C., which formed portions of a large, mosaic, faïence wall decoration. Moreover, there are in existence many modeled reliefs of faïence from the middle and late Minoan period which were apparently inserted in the plaster of walls.

Farther east, in the Tigris-Euphrates valley, a tradition of ceramic wall decoration was early established. (*See IRAN: Archaeology.*) This took the form of glazed and enameled bricks rather than tiles proper. It is, nevertheless, important as being one of the first attempts to cover large and continuous wall surfaces with a decorative, ceramic material, and the friezes of marching beasts from Chaldean and Babylonian palaces, from the later Assyrian palaces and from their Persian successors, the famous friezes of the archers and the lions from the early 4th-century palace of Artaxerxes II at Susa, have remained models of this type of decorative work.

Moreover, the tradition of fine ceramic work continued vital throughout the stormy period of the fall of the Roman empire and the Islamic conquest. It is in Syria, the Tigris-Euphrates valley and Persia that wall tiles were, undoubtedly, first made. Thus tradition relates that the lustre tiles of the mosque of Sidi Okba at Kairouan were brought from Baghdad in 894, and it is certain that by the 13th century the manufacture of wall tiles for both exterior and interior use was well established in various centres in Persia, notably Rhages and Veramine. The exterior use of wall tiles was most highly developed, and in Persia, also, the transition from enameled and modeled brick to true, thin tile can easily be seen. By the 15th century tile decoration was supreme in Persia

and the character had changed. Mosaics and moldings in relief yielded to a flat treatment with the richness entirely in the coloured, foliated ornament and the inscriptions painted on the tiles themselves. In later Persian art there is no distinguishable difference between the tiles of the exterior and the interior.

These Persian tiles governed the taste of the eastern part of the Islamic world; the same running patterns of leaves, palmettes, the carnation and other flowers that appear on Persian carpets decorate alike the interiors of mosques in Persia, Mesopotamia and Turkey, from potteries as far apart as Rhodes, Damascus and Kutayieh. In colour these have, universally, a blue-white ground with patterns predominantly blue and green, with lesser touches of vermilion and rose and occasional yellows. Several potteries in Asia Minor still operate and produce exquisite wall tiles in the traditional patterns and colours. Because of the gracious delicacy of the interlacing stems and the careful spacing of the leaves and flowers, together with a springlike clarity of the colours, these Turkish, Syrian and Persian wall tiles are among the most perfect wall decorations of their type.

**Moorish Wall Tile.**—Farther west, in Spain and North Africa, the Islamic potters were developing a new type of design which gave rise to the famous Spanish *azulejos*, whose decorative richness was such an important feature in the Alhambra (*q.v.*) at Granada (13th and 14th centuries), the so-called house of Pilate at Seville and similar buildings. Although transitional types occur, like the great plaque from Malaga at the beginning of the 15th century in the collection of M. de Osma, in which the patterns are of an almost Persian freedom, with twining foliage, in the greater number the design was almost purely geometric, being formed of interlacing lines that generate 8- and 10-pointed stars, octagons, irregular pentagons and similar figures. There are, in addition, a great many early tiles from the 13th and 14th centuries in which the influence of Christian heraldry is dominant. Even in the transitional plaque mentioned above, coats of arms appear and it is evident that the Islamic potters produced much purely heraldic tilework for Christian consumption. Many of these tiles are rich with metallic lustre decoration; the chief colours are blue, green and brown, with white lines, and in the later work a growing use of black and yellow.

The earliest examples of Moorish wall tiles produced their geometric patterns by a mosaic method in which each bit of separate colour is formed by a separate tile. In order to develop a more facile method of producing the same effect, the technique known as *cuerda seca* (dry cord) was developed, in which the tiles are rectangular, and the pattern on each tile is formed by raised fillets between the different colours, which prevented the adjoining enamels from running together. After the Christian conquest a third method was introduced, called *cuenca* (bowl), somewhat similar to the northern Gothic process in which the portions to be coloured were depressed and then filled with their enamels. These tiles, even in their old traditional Islamic patterns, were popular throughout the 16th century and even later for wainscots in Renaissance houses. The potters were evidently Moors; the great centres of manufacture remained as before in Malaga, Valencia, Granada and Seville.

In the 16th century the Italian majolica type of tile was introduced by Francesco Niculoso of Pisa, and these Spanish majolica tiles were much used, as in the door of the convent of St. Paula at Seville (early 16th century) or the exquisite altarpiece in the Alcázar at Seville made by the same artist in 1503, where the design is purely Italian. Both the *cuenca* and the *pisano* or majolica types of tile have been made in Spain almost continuously ever since. (*See ISLAMIC ART.*)

**North European Wall Tile.**—Meanwhile in Germany there had been developing a type of tile used principally for stoves, with ornament in relief and a glaze of green, yellow or brown. This tile was in widespread use as early as the 14th century and many examples exist throughout Germany, upper Austria and Switzerland, in which the ornament is of great richness, with Gothic architectural forms in the earlier types and Renaissance forms later.

The most important of the north European tiles are undoubt-

edly those made in Delft, Neth., from 1600 on. These are plain, square tiles, each containing a figure, a bit of landscape or a genre group, freely painted in a gray-blue upon a background of bluish-white. The little freehand sketches were so instinct with life, and the colour so subtly beautiful, that by the middle of the 17th century these tiles enjoyed a great vogue, not only throughout the Germanic countries but in England and the American colonies as well. Although outside of the Netherlands they were chiefly used for fireplace and stove facings, in the Netherlands itself they were often employed for wall wainscotings. Some of the later examples have the decorations in manganese purple instead of blue. During the 18th century many attempts were made to imitate the delftware and during the latter half of the 18th century, particularly in England, scenes printed from copper plates were used instead of the painted scenes.

Although many ancient pottery centres still produce tiles in the traditional manner and although modern imitations of old wares are of excellent quality, the greatest modern contribution to wall-tile design was the development of square or rectangular tiles with relatively uneven surfaces and shapes on which colours and glazes of the greatest variety are unevenly flowed, so each tile has individuality of colour and texture. All sorts of crackled and crystalline effects are common, as well as the blending of colours. Scientific development of glazings and colourings gave the decorator an almost unlimited palette for exterior or interior use. There was also development in the use of tile in relief, usually with the background sunk and glazed in a different colour.

During the late 19th century, light, flat tiles often provided an ideal material for vaults and domes. Their advantages over wood and stone had earlier been recognized by the Romans, who laid flat tiles vertically and horizontally between thick brick ribs in order to lighten vaults, keep them fireproof and gain both support and form for the concrete infilling poured between ribs. The biggest 19th-century innovation was the Guastavino vault, named for a Catalan engineer who developed a light, fireproof vault in which bonded layers of small, light and flat tiles were built into curved surfaces with a minimum of centring. Especially popular in the United States, examples of the Guastavino vault appear in New York's Carnegie hall and St. Thomas's church; St. Paul's chapel at Columbia university, New York city; Boston's public library; and the state capitol at Lincoln, Neb.

Cheaper materials compete with traditional kinds of tile and are called tiles even though some are not made of terra cotta. Fibre-board sound-absorbing panels, referred to as "acoustic tiles," are used in modern ceilings. Glass block, sometimes called "Glasstile," appears in partitions. A wide variety of mass-produced ceramic veneers is available in different colours, finishes, textures and shapes, though figurative patterns are unusual. Ceramic-glazed structural tile, hollow and approximately  $3\frac{1}{2} \times 3\frac{1}{2} \times 11\frac{1}{2}$  in. in size, remains an attractive, economical and permanent material for partitions in schools, hospitals, railroad stations and cafeterias.

**TILIACEAE**, the linden family of trees, shrubs or (rarely) herbs, with 35 genera and about 300 species, found in most parts of the world, but largely tropical. Most of the genera are small, but *Grewia*, in the old world tropics, contains about 70 species. *Tilia*, various species of which are known as linden and as bass-wood (originally bast wood), is typical of the north temperate zone of both hemispheres. The bast of many representatives of the family is tough and strong; two species of *Corchorus* yield the jute (*q.v.*) of commerce, largely produced in India. See LINDEN.

**TILLAGE MACHINERY.** Tillage includes soil management practices such as reducing residues of previous crops, plowing, harrowing, rolling and cultivating. The primary purposes of tillage are to prepare the seedbed, to retard weed growth and to improve the physical condition of the soil. Manures and fertilizers often are applied in connection with tillage operations.

The field operations that accomplish these purposes include: (1) crop-residue treatment; (2) primary tillage or plowing; (3) secondary tillage, or harrowing (refining the seedbed); (4) cultivation (primarily to retard weed growth); (5) fertilizing and manuring; (6) subsoiling or deep tillage. The kinds of machinery needed depend on the type or combinations of practices employed, and are dealt with under the following headings:

- I. Implements for Treating Crop Residues
  1. Stalk Cutters
  2. Rotary Cutters or Shredders
- II. Primary Tillage or Plowing Implements
  1. Moldboard Plow
  2. Tractor-Mounted Plows
  3. Two-Way Plows
  4. Listers and Middlebusters
  5. Disk Plows
  6. Disk Tillers
  7. Rotary Plows
- III. Secondary Tillage or Harrow Implements
  1. The Disk Harrow
  2. The Spike-Tooth Harrow
  3. Spring-Tooth Harrows
  4. Special Harrows
  5. Clod Crushers, Packers and Mulchers
- IV. Cultivation or Hoeing Implements
  1. Row-Crop Cultivators
  2. Field Cultivators
  3. Rotary Hoes
  4. Rod Weeders
  5. Spring-Tooth Weeders
- V. Subsoiling or Deep Tillage Equipment
  1. The Subsoiler
  2. The Chisel Plow
- VI. Fertilizer Distributors
  1. Manure Spreaders
  2. Distributors for Commercial Fertilizers
  3. Broadcast Distributors
  4. Distributors for Anhydrous Ammonia
  5. Applying Fertilizer Solutions
- VII. Small-Scale Tillage Equipment

## I. IMPLEMENTS FOR TREATING CROP RESIDUES

Although most tillage implements mix crop residues with the soil, certain special implements are used for reducing the stalks of cotton, corn (maize) and other crops having heavy stalks.

**1. Stalk Cutters.**—These are made in animal-drawn and tractor-drawn sizes. The former has one section, of suitable width for cutting down the stalks of two rows of corn or cotton; the latter employs two sections and covers four rows. The free-rolling cutting cylinder, with eight or ten sharp-edged knives mounted equidistant from their axis of rotation, is weighted to give a thorough cutting action as the cylinder rolls through the field. Some models have wheels for transport and depend for pressure upon a heavy compression spring. Others are transported by turning the unit upside down and using the transporting runners mounted on the upper side of the implement.

**2. Rotary Cutters or Shredders.**—Cutters or shredders are used for shredding stalks of cotton and corn, chopping prunings from orchards, cutting crops for silage and mowing pastures for weed control. These machines have many different names, including field shredder, brush beater, rotocycle and hammer knife mower. Tractor-mounted and -trailed models are available; both are driven by the tractor power take-off. One type uses a long horizontal shaft to which are attached flails or hammers. When rotated at high speed the pounding action reduces the stalks or trash to a fine mulch. Other types have knives which cut rather than lacerate. Power-driven rotary cutters do more satisfactory work than the rolling stalk cutter.

## II. PRIMARY TILLAGE OR PLOWING IMPLEMENTS

The main objectives of primary tillage are to loosen and aerate the soil, invert it to cover trash and weed seeds and expose a large

BY COURTESY OF JAMES AND FREDK. HOWARD LTD.

FIG. 1.—PARTS OF A SINGLE-FURROW WALKING HORSE-DRAWN PLOW WITH LEA BREAST

area of fresh soil to weathering so it can be more readily harrowed into a good seedbed. The implements for primary tillage include moldboard plows, disk plows, listers, middlebusters or middlebreakers, one-way disk tillers and rotary tillers.

**1. Moldboard Plow.**—In its simplest form this is a single-furrow, animal-drawn implement held by the plowman who walks behind it. It consists of a beam to which is attached a pair of handles for controlling it; a bottom made up of a share (lay or sock) for cutting the furrow slice loose; the landside for taking the side thrust; a moldboard or breast for turning the furrow; braces; a colter for cutting a vertical side or wall of the furrow (this may be a vertical knife, a circular knife or a rolling-disk colter); and an adjustable hitch. Most European and some U.S. plows have one or two gauge wheels at the front end of the beam that help keep the plow level, steady and at uniform depth. In oriental countries gauge wheels are not commonly used and depth control depends on adjustment of the clevis, or hitch (see fig. 2), at the front of the plow. This clevis also provides for adjusting the width of cut.

Fig. 1 is typical of an English walking plow and fig. 2 of a U.S. walking plow, and the essential parts are named there. The principal parts of moldboard plow bottoms are similar in walking plows and tractor plows. Because soil conditions vary greatly throughout the world, many different shapes of bottoms are required, and several different materials are used. The basic shapes are shown in fig. 3. Not shown is the breaker bottom with its long, easy-turning moldboard, adapted to virgin or tough sod. The English lea bottom (see fig. 1) is used mainly in sod and for fall plowing, and the English digger bottom—similar to the stubble bottom—is used for spring plowing.

Plain cast iron is preferred for sandy soils, which scour easily. But chilled cast iron, hardened by a special process, scours even better, resists abrasion well and is more widely used. Solid (crucible) steel is favoured where there are many rocks and stones because of its resistance to breakage. Soft-centre steel (two outer layers of hard steel cushioned by an inner layer of soft steel) is generally used in heavier soils.

Coverage of trash and weeds is improved by a rolling colter and skim colter, or jointer. Used together, they cut the edge of the furrow slice cleanly, tear off a corner of the slice with its projecting grass or weed growth and deposit it in the open furrow where it is well covered. These attachments may be used separately.

Width of furrow cut by single furrow plows varies from 6 to 12 in. These smaller sizes are commonly used in countries—India, Mexico, Japan, China—where they are drawn by animals.

Moldboard plows, powered by farm tractors, vary in the width of furrow from 10 in. for a small, single bottom to 96 in. cut by six 16-inch bottoms of large tractor plows. Tractor plows are drawn behind the tractor or mounted on it. Smaller sizes with one or two bottoms are usually mounted, although available as trailed models also. Larger sizes with three or more bottoms are tractor drawn. They have wider bottoms. Some can plow 12 in. deep, although usually moldboard plowing is much shallower. An extremely large size is used in the western United States for making ditches and for mixing fertile subsoil with surface soil. Its huge, single moldboard turns a furrow six feet wide and three feet deep.

Tractor-drawn plows are attached with an adjustable hitch. This permits horizontal adjustment to insure correct width of the front furrow, and vertical adjustment to prevent nosing (down-

ward tilting of plow points), which causes rapid wear of the underside of the share point and gives poorly turned furrow slices.

A spring release or other protective device is incorporated in the hitch. This disconnects the plow when it strikes a firmly anchored obstacle. In some tractor plows the protecting device is applied to each bottom individually, as each bottom is held in working position by a heavy spring. Should it strike an obstruction, the spring permits the bottom to raise and pass over the obstruction.

Tractor-drawn plows have a lifting mechanism to raise them from or lower them to their working position. This may be either mechanical or hydraulic. The mechanical lift is controlled through a cord pulled by the tractor driver. The cord actuates a clutch usually located in the land wheel (the wheel that runs on the unplowed ground). The clutch connects or disconnects the motion of the wheel to a crank which raises or lowers the plow. Two principal levers may be furnished on tractor-drawn plows, one for regulating depth and one for leveling the plow.

**2. Tractor-Mounted Plows.**—The tractor and the mounted plow are a compact unit, easily maneuverable and readily adjusted by the operator. Mounting plows, cultivators and other implements marked a milepost in the development of farm machinery. Prior to this development, the tractor was in a sense simply a mechanical draft horse.

The mounting of implements led to the development of hydraulic controls. The control levers are placed on the tractor itself rather than on the implements. Hydraulically controlled mounted implements showed so many advantages that in some countries—New Zealand, for instance—they became widely used within a very few years.

The hydraulic system consists of a pump driven by the tractor engine, an oil reservoir and distribution lines that convey the hydraulic liquid under pressure to a piston enclosed within a cylinder. The piston transmits the hydraulic force to the leverage of the plow or other implement. Hydraulic cylinders are of two types, one-way and two-way. The one-way has a piston that can exert pressure in one direction only; the two-way piston may receive hydraulic pressure from either side and so can exert pressure in either direction and either lift a load or force it downward. Hydraulic power is applied to the control of many implements, both mounted and trailed. With trailed implements the hydraulic cylinder is placed on the implement. Hydraulic liquid under pressure is conveyed to the cylinder through heavy hoses.

Mounting implements on the tractor also brought methods for quickly attaching and detaching such implements. The operator can attach or detach a plow or other implement without leaving the tractor seat. This convenience not only saves time but also lessens danger, since the operator need not stand behind the tractor when attaching an implement. (See further TRACTOR.)

**3. Two-Way Plows.**—Two-way, or reversible, plows are used in hilly regions, in irrigated fields where dead furrows (open trenches) are a hindrance in controlling water and in irregularly

BY COURTESY OF JOHN DEERE

FIG. 2.—HORSE-DRAWN WALKING PLOW

shaped fields. They have a right- and left-hand plow bottom, one of each on animal-drawn plows and generally two of each on tractor plows. The operator can plow in either direction and throw all the furrows one way, thus eliminating all dead furrows, or he can throw all the furrows uphill to maintain soil in proper place for contour plowing. Two-way plows are available in walking models and in tractor-mounted and tractor-drawn models. The "turn-wrest" plow is a walking model used in India, where it is drawn

by two bullocks. After releasing a latch, the plowman can manually turn (wrest) the beam so as to alternately use the right and left bottoms.

**4. Listers and Middlebusters.**—The term middlebuster is used where crops are planted on beds, and the term lister where they are planted in the open furrow. Both listers and middlebusters have a right- and a left-hand bottom mounted back to back. They prepare ridges for cotton, potatoes, sweet potatoes and other crops that are planted on the tops of shallow beds. Listers and middlebusters are essentially the same. However, the lister moldboard is of the general-purpose shape, while the middlebuster moldboard is more like the black-land moldboard. The right and left moldboard on both listers and middlebusters are joined together so they throw furrow slices in both directions at one time. In semiarid regions the lister ridges the soil to preserve moisture and to lessen wind erosion.

BY COURTESY OF JOHN DEERE

FIG. 3.—PLOW-BOTTOM TYPES  
(A) Stubble; (B) general-purpose;  
(C) general-purpose, for clay and stiff-  
soil; (D) slat; (E) blackland; (F)  
chilled general-purpose

It is also combined with a planter which drops seeds into the open furrow to be covered by a planter attachment.

The listers and the middlebusters range in size and design from the single-bottom, animal-drawn units to the giant tractor models with six bottoms. A variety of bottoms can be used with a tractor employing the tool-bar method of mounting. The tool bar can carry different tillage tools. It is a heavy steel bar, usually square, mounted across the rear of the tractor. The bar itself is connected to the linkage operated by the tractor hydraulic system. Accordingly, implements attached to the tool bar are controlled by the hydraulic system. Also, the ground-working tools can be spaced horizontally on the tool bar as desired. Tool bars with their own wheels are also furnished as tractor-drawn units.

**5. Disk Plows.**—The disk plow has one or more concave disks varying in diameter from 20 in. for animal-drawn models to 40 in. for tractor models. Disk plows work well in dry, hard soils where moldboard plows penetrate with difficulty, and also in sticky soils where moldboard plows do not scour well. They also work satisfactorily in land having rocks or stones because the disks ride over such obstructions without breakage, and they are effective in loose soil and where there are many roots, shrubs and bushes.

Small tractor-mounted models may have only one disk; but large, tractor-drawn sizes may have seven or more. Most tractor models are controlled hydraulically, although some have a mechanical power lift.

The angle of the disks is adjustable vertically and horizontally. Adjusting the disk nearer to a vertical position makes it penetrate better. Adjusting it closer to a line perpendicular to the direction of travel makes it cut wider. In some models, the distance between the disks may be varied. Penetration depends upon field conditions, the diameter of the disk and the weight placed upon the disks. Accordingly, disk plows are quite heavy and wheel weights are often required to improve penetration.

**6. Disk Tillers.**—These ruggedly built tractor implements have the disks set at a fixed angle of about 45°, and the disks are smaller than those of the disk plow. They do not penetrate as deeply and they mix surface growth with the soil rather than invert it. They are used to mix the stubble of the previous crop with the surface soil, but leave enough stubble exposed to retard wind erosion and to improve water infiltration. Small sizes, about five feet wide, may be tractor mounted or semimounted. Large sizes, with sixteen 24-in. disks spaced about 9 in. apart, may cut a 12-ft. swath. Hence, the rate of work is fast—up to 50 ac. per day. A special type, developed in Australia, is the stump-jump disk cultivating plow. The disks are assembled in pairs, each pair being held to its working position by spring pressure. When a solid obstruction is encountered a pair of disks can rise over the obstruction, against the spring pressure, without disturbing the rest of the implement. Modifications of this stump-jump plow are used in the range lands of the western United States.

Disk tillers are known also by other names, such as one-way disk, harrow plow, wheatland disks and vertical disk plow. Some may have a seeding attachment so that certain crops can be seeded at the same time the seedbed is prepared. (See also PLANTING MACHINERY.)

**7. Rotary Plows.**—Rotary plows have been used in Europe for many years. They employ an assembly of tines or knives mounted on a horizontal, power-driven shaft. The smallest sizes, powered by garden tractors, cut a swath of about 12 in.; larger garden tractor models cut a 30-in. swath. Large rotary tillers cut up to a 6-ft. swath, require up to 90 h.p., and may have a separate engine mounted on the tiller itself. Other models are mounted on farm tractors and driven by the power take-off.

In most designs the rotating knives cut on the downward stroke and mix the surface growth evenly throughout the seedbed. Depth of cut can be varied through a wide range. Hence, rotary tillers are used not only for preparing seedbeds but also for surface cultivation.

Under favourable conditions rotary tillers prepare a seedbed in one trip over the ground. However, when conditions are difficult the rotary tiller can make a second trip over the tilled ground, which is not feasible with a moldboard plow.

### III. SECONDARY TILLAGE OR HARROWING IMPLEMENTS

Various types of harrows are used to refine the seedbed, to level the plowed soil, compact it and destroy weed seedlings.

**1. The Disk Harrow.**—A truly general-purpose implement, the disk harrow is sometimes used before plowing and quite generally after plowing. Disk harrows have gangs of disks assembled so that the side forces are balanced. One gang throws the soil to the right, the other to the left. Single-cut, animal-drawn disk harrows give a width of cut from four to six feet. Tractor disk harrows are usually of the tandem type having two gangs in front and two in the rear, thus giving a double action.

The offset tractor disk harrow has only two gangs; one is behind the other, somewhat like one-half of a tandem harrow. The two gangs throw the soil in opposite directions, the rear gang re-

BY COURTESY OF INTERNATIONAL HARVESTER CO.

FIG. 4.—TRACTOR-MOUNTED TANDEM DISK HARROW WITH FAST-HITCH CONNECTION

working the soil moved by the front gang so as to leave it quite level. This type is commonly used in orchards and vineyards because the operator can get under projecting branches and near to the trees or vines.

Penetration may be regulated by adjusting the angle of the disk gangs. In animal-drawn models this is accomplished by levers found on each gang. Tractor-drawn harrows may employ a power-angling device operated by movement of the tractor, or a hydraulic cylinder may be used to control the angle.

Some large tractor models are supported by transport wheels and the gangs are set at a fixed angle. Penetration is regulated by raising or lowering these transport wheels by hydraulic power.

Tractor disk harrows, five to eight feet wide, may be fully mounted, making them convenient for working in the corners of fenced fields. Larger tandem tractor harrows may cut a swath as wide as 14 ft. Special single-cut tractor harrows (up to 20 ft. wide) are used for controlling weeds on summer fallow and to reduce stubble and corn stalks previous to plowing.

**2. The Spike-Tooth Harrow.**—This implement aids materially in breaking up clods and leveling fields, and may be used for covering seed. It consists of a number of horizontal bars to which teeth or tines are attached. The teeth are spaced so that each tooth makes a separate cut through the soil; no one tooth trails another. With a typical five-foot section every two inches of ground is cut by a tooth. The number of sections used depends upon the power available, varying from perhaps only one section when drawn by an animal to eight six-foot sections for large tractors. Some tractor models are wheel-supported and the sections can be folded for transportation.

**3. Spring-Tooth Harrows.**—These also are made in sections with horizontal tooth-retaining bars. The flexible spring teeth are more widely separated than in the spike-tooth harrow. They resist damage from stones or other obstructions and penetrate well in hard ground. An implement of suitable width can be obtained for whatever power is available. Some models are carried on transport wheels that aid in regulating the depth. In others, depth is controlled by levers that change the position of the spring teeth. With some types the operator can clear the teeth of trash without leaving the seat of the tractor.

**4. Special Harrows.**—Specially designed harrows are used for intensive grassland cultivation. Chain harrows, consisting of studded metal links fastened together like a net, brush harrows (made by drawing brushwood through a frame in such a way as to form a rough smoothing surface) or spike-tooth harrows are used in the spring for dragging out moss or matted undergrowth and dispersing lumps of manure, molehills, etc.

**5. Clod Crushers, Packers and Mulchers.**—These are used to break up lumps left by harrows and to compact the soil, thereby eliminating large air spaces. The plain roller is often used to compact grassland damaged by winter heaving. It is used frequently on alfalfa fields also. Corrugated rollers—single or tandem—crush clods and firm the soil after plowing. After wheat is sown, the corrugated roller compacts the soil around the seed to improve germination, and the corrugations left on the surface reduce soil-blowing.

Another effective clod crusher and packer is made of a series of sprockets loosely fitted at the hub and mounted on an axle between sharply ridged rollers. In moist soil the lagging of the sprockets lessens clogging of the ridged rollers. In England, land pressers or packers often are used. These have heavy wedge-shaped wheels about three feet in diameter. They are used in dry seasons to compress the soil at the bottom of the furrow; some designs may be hitched directly behind the plow to press down the freshly turned furrow slices.

#### IV. CULTIVATION OR HOEING IMPLEMENTS

In general, weed destruction is the primary purpose of cultivation (hoeing). Cultivating implements can be divided into three main classes: (1) row-crop cultivators; (2) field cultivators; and (3) rotary hoes.

**1. Row-Crop Cultivators.**—These implements employ various shapes of steel shovels to work the soil. Typical shovels are short,

narrow, slightly curved, pointed steel pieces with polished front surfaces that dig into the soil in proportion to the pressure applied. For very shallow cultivation, special shovels or sweeps (sometimes called duck-foot sweeps) are available in different widths.

Row-crop cultivators range in size from one-horse, between-row walking types to tractor models for cultivating (astraddle) six rows or more at a time. The kind and number of shovels used per gang depend on the crop and the soil characteristics. Shovels or sweeps are sometimes replaced by disks or disk hillers when a considerable quantity of soil is to be moved, or where trash and vines must be cut. The gangs carrying the shovels of a tractor cultivator may be front-mounted, centre-mounted or rear-mounted. Some designs combine a centre and rear mounting and others carry the cultivating steels on tool bars.

**2. Field Cultivators.**—These are designed primarily for open-field rather than row-crop cultivation. They are used also for controlling weeds in summer fallow, for renovating pastures and for stubble mulching. The large models are wheel-supported and hydraulically controlled. The cultivating tools may be spring teeth, shovels or sweeps. When equipped with spring teeth the larger, sturdier models penetrate deeply.

**3. Rotary Hoes.**—The rotary hoe works best when the tractor is operated at a fairly high speed. It is made up of gangs 42 to 46 in. wide. Within the gang a group of 14- to 20-in. hoe wheels, with radial projecting fingers, is mounted on a horizontal axle. Several gangs or sections are combined to make a tractor unit—sometimes 12 sections, which would cut a 40-ft. swath. Each section is of proper width to cover a typical corn row and has about seven hoe wheels. The rotary hoe is particularly useful in the early growth stages of corn and other row crops, and is effective in breaking crusts caused by hot sunshine after a hard rain. Sometimes the gangs are assembled in tandem to obtain double action.

When the rotary hoe is drawn backward the teeth do not penetrate. Instead, they give a treading action which crushes clods and pulverizes stalks and surface residue. One section may be used behind the plow to pack the freshly turned furrow slices.

Special rotary-hoe attachments are used with row-crop cultivators. These narrow attachments work directly on the row of plants, while the shovels work between the rows.

**4. Rod Weeders.**—The rod weeder is used for weed control in open fields where summer fallow is practised. Its working element

BY COURTESY OF JOHN DEERE

FIG. 5.—TRACTOR-DRAWN ROD WEEDER

is a square, horizontal rod driven by one of the supporting wheels and revolving one to five inches below the soil surface. Roots and weeds are caught on the rod and pulled out, but do not collect on it. Sizes vary from 8 to 12 ft. in single units up to combinations of sections sufficient to cut a 36-ft. swath.

**5. Spring-Tooth Weeders.**—These have light spring teeth designed for destroying surface weeds only. They can be operated directly over the rows of growing plants because the light, wirelike teeth flick out the shallow-rooted weeds without injuring growing plants. These implements reduce the number of later cultivations because they destroy weeds effectively just as they emerge.

#### V. SUBSOILING OR DEEP TILLAGE EQUIPMENT

Heavy tillage implements are employed to encourage deeper root growth, to break up hardpan and compacted soils and to improve

water infiltration. With tool bars, heavy ground-working tools can be used—large disks, heavy tines, shovels of various types, chisel points and subsoil blades. Such heavy equipment is often required for the hard, rough conditions frequently encountered in tropical agriculture.

**1. The Subsoiler.**—This implement employs a single long shank carrying a steel point. The various sizes and lengths of shanks permit penetration from 16 to 36 in. Draft of this implement is great, and larger sizes require a powerful tractor. The subsoiler opens a slit in the soil through which moisture can enter; it reduces compaction caused in some areas by implement traffic on the field. By improving water infiltration it reduces runoff and erosion.

A mole, shaped like a bullet or ball, is sometimes attached to the rear of the subsoil point. Such mole plows are used for draining land having a clay subsoil. The mole may be set to work at different depths and when drawn through the ground compresses the subsoil in its passage, leaving a drainage channel of its own diameter. The narrow slit cut by the subsoiler shank closes up and water then passes into the drain by percolation. Mole drains thus prepared should have suitable outlets and a natural gradient following the contour of the land.

**2. The Chisel Plow.**—This plow has a number of shanks mounted on a transverse tool bar. Horizontal distance between the shanks may be adjusted, from 12 in. to 3 ft. apart, to suit field conditions. The work of the chisel plow is similar to that of the subsoiler, but shallower. Either rigid tines or spring-tooth shanks are used. They may penetrate as much as 18 in. and can also be used for shallow tillage. The shanks may be fitted with various shapes of steels such as narrow, double-pointed shovels, or wide sweeps for shallow tillage.

## VI. FERTILIZER DISTRIBUTORS

**1. Manure Spreaders.**—The manure spreader carries manure, tears it up and spreads it on the field. The basic design has remained that of a four-wheeled wagon, although tractor models may have only two wheels and have the front of the spreader supported on the tractor. The distributing mechanism consists of a drag-chain conveyor at the bottom of the box. This carries the manure to the rear of the spreader where it is shredded and scattered. This is accomplished by an upper beater that levels and shreds the manure as it is driven into the lower spike-tooth beater, which tears it to bits. Wide rotating spiral fins complete the operation by spreading the manure widely in a uniform layer, the thickness of which is determined by the speed of the conveyor.

Both animal-drawn and tractor-operated spreaders are available. Some models have the distributing mechanism driven by the tractor power take-off; in others it is driven by the spreader wheels. Capacity is determined by the size of the box, which varies from 50 to 140 bu.

Loading manure spreaders by hand is a laborious and unpleasant task. Hence it is often done by tractor-operated loaders. These are powered by the tractor engine and controlled hydraulically.

**2. Distributors for Commercial Fertilizers.**—Commercial fertilizers are available in solid, gaseous and liquid form. Anhydrous ammonia, a popular source of nitrogen, is liquid under pressure but becomes a gas when it is freed from this pressure as it enters the soil.

Distributors for solid commercial fertilizers must give a uniform distribution whether heavy or light applications are being used. It is important that distributors can be easily cleaned because some fertilizers are highly corrosive. Solid-fertilizer distributors differ mainly in the method of distributing the material. Most designs have a wide hopper that carries the material. Wheels at the ends of the hopper serve for transport and also drive the distributing mechanism. Distribution in some models is effected by a roller at the bottom of the hopper. This revolves so as to work the fertilizer out backward as the machine advances. Other designs have agitators placed over holes in the hopper bottom. Another uses an endless chain with projecting fingers which travel across the bottom of the hopper. Still another employs rotating fingers which work the fertilizer out. In several types the material

falls straight down to the ground and is distributed along the full width of the machine. However, some designs use tubes for distributing the material in rows.

**3. Broadcast Distributors.**—These are quite different in design. They have a tub-shaped hopper from which the solid material falls on to two revolving disks, which are driven by the spreader wheels. The broadcaster may be drawn behind a motor truck or other vehicle, from which its hopper is filled. The revolving disks distribute fertilizer, lime or marl (clay and lime) in a broad swath, up to 20 ft. wide. Lime also is applied with an end-wheel type of distributor having a hopper about eight feet long.

**4. Distributors for Anhydrous Ammonia.**—These distributors require a heavy tank because this material must be stored under considerable pressure. Application is controlled by carefully designed valves and an accurate metering device. The ammonia passes through heavy tubing to applicator teeth that cut gashes four to six inches deep through the soil. When released at this depth the ammonia gas is sealed in by the soil falling above it. Anhydrous ammonia applicators may be obtained as tractor-trailed or -mounted models. Attachments are also available for row-crop planters.

**5. Applying Fertilizer Solutions.**—Water solutions of nitrogen and also solutions containing all three major plant foods—nitrogen, phosphorus and potassium—are available. Applicators may employ boom-type sprays with nozzles, as these solutions can be sprayed on pasture, small grain or the soil without loss of nitrogen to the atmosphere. Some applicators have a number of rubber or plastic hoses, attached to the ends of the boom openings, which drag on the ground and apply the solution to the surface. The rate of application is controlled by a metering device or by a positive type of pump that regulates flow from the tank. See also FERTILIZERS AND MANURES.

## VII. SMALL-SCALE TILLAGE EQUIPMENT

For market gardeners, horticulturists, amateur gardeners and growers with small acreages a wide variety of tillage tools is available to fit practically every requirement. This includes garden tractors—both walking and riding—that are provided with tilling and cultivating implements suitable for many purposes. For the garden there are many hand-operated tools such as the push-hoe cultivator and seeder, as well as a wide assortment of tools.

Farm machinery dealers and hardware merchants can furnish information on practically any kind of tillage tool or advise customers where it can be obtained.

See also FARM MACHINERY; TRACTOR.

**TILLET, BENJAMIN** (1860–1943), British trade union leader, better known as Ben Tillett, played a notable part in the organization of unskilled workers. He was born in Bristol on Sept. 11, 1860, the son of a railway labourer. He went to work in a brickyard at the age of seven and then was a circus boy, a sailor in the Royal Navy, a merchant seaman, and an apprentice bootmaker. By his early twenties he was settled in the east end of London, devoting himself to the organization of the Dock, Wharf, Riverside, and General Workers' Union, of which he became general secretary. He played a colourful and decisive part in the successful dock strike of 1889, which led to the achievement of the "dockers' tanner" (a minimum wage of 6d. an hour) and a great spurt in union membership. He was equally active in the dockers' strike of 1911. He was Labour member of Parliament for North Salford, Lancashire, from 1917 to 1924 and from 1929 to 1931. His trade union work was somewhat eclipsed after 1921 when his union amalgamated with others to form the Transport and General Workers' Union, but he was chairman of the Trades Union Congress in 1928–29. He was for many years an alderman

of the London County Council. He died in London on Jan. 27, 1943. His publications include an autobiography, *Memories and Reflections* (1931), and *A Brief History of the Dockers' Union* (1910). (R. J.)

**TILLEY, SIR SAMUEL LEONARD** (1818–1896), Canadian statesman who introduced the “national policy” of tariff protection, was born at Gagetown, New Brunswick, on May 18, 1818. After making a small fortune in drugs, he entered the legislature in 1850, becoming head of the New Brunswick government in 1861. He represented the province at the conferences at Charlottetown and Quebec in 1864, at which the plans for Confederation were prepared.

In 1865 he was defeated in a general election on the federation question, and the reverse delayed Confederation for almost a year. In 1866 his position was vindicated and he was returned to power at the head of a pro-Confederation government. He became the first minister of customs and excise for the Dominion of Canada, in 1867.

In 1873 he left politics to become lieutenant governor of New Brunswick, but in 1878 was again returned to Parliament for Saint John and entered the government of Sir John A. Macdonald as minister of finance, where he espoused the “national policy.” The tariff that resulted thereafter remained the basis of Canadian fiscal policy. He again became lieutenant governor of New Brunswick, from 1885 to 1893. He died at Saint John on June 25, 1896.

See James Hannay, *Sir Leonard Tilley* (1926). (W. S. MacN.)

**TILLICH, PAUL JOHANNES** (1886–1965), German-U.S. philosopher and theologian, a widely influential apologist in the Christian church, developed a distinctive interpretation of the task of Christian theology by correlating biblical faith with the questions raised by classical and modern philosophy, especially mysticism, idealism, and existentialism. He was born in Starzedel, Brandenburg, on Aug. 20, 1886, the son of a pastor and district superintendent in the Prussian territorial church. Tillich studied in the University of Berlin and other German universities, receiving the doctor of philosophy degree from Breslau in 1911 and the licentiate in theology from Halle in 1912. He served in the German army as chaplain from 1914 to 1918. After the war he taught in the universities of Berlin, Marburg, Dresden and Leipzig, and in 1929 became professor of philosophy at the University of Frankfurt. Tillich was one of the first professors to be forced from his post by the Nazi regime in Germany. In 1933 he went to the United States where he became professor of philosophical theology (1933–55) at Union Theological seminary, New York city. During World War II he served on the Committee for a Democratic Germany and was chairman of the Committee on Self-Help for Refugees. In 1955 he became university professor at Harvard university and in 1962 Nuveen professor of theology at the Divinity school of the University of Chicago. He died in Chicago on Oct. 22, 1965.

Tillich's early writings include his thesis on Schelling, who, along with Jakob Böhme, was one of the most important influences on his thought. During the Weimar republic Tillich aligned himself with a group of German intellectuals in the Religious Socialist movement which sought a new spiritual outlook coupled with effective power to renew and shape the political order (see CHRISTIAN SOCIALISM). In two books, *Religious Realization* (1930) and *The Religious Situation*, Tillich gave a powerful analysis of the religious and cultural dilemmas of 20th-century man.

Tillich stands in the tradition of the great synthesizers of Christian doctrine—Origen, Augustine, Aquinas and Schleiermacher.

He developed a method of relating traditional Christian doctrine to the questions which arise from the human situation, his technical term for the method being “correlation.” Man's questions become religious when they express his “ultimate concern,” that is, his concern about what determines his being or his nonbeing. The questions are correlated in theology with the answers which come from the self-manifestation of the divine reality. Such manifestation is the meaning of revelation. The answers to the meaning of man's existence cannot be grasped abstractly but only through personal faith and decision.

Tillich's theological position required and permitted him to develop a systematic analysis of cultural expressions of the human spirit. He gave careful attention to depth psychology, existentialist philosophy and to the arts, especially painting, as these provide keys to the human quest for final meaning.

As theologian, Tillich stands within the “theological circle” which is determined by Christian faith. The final criterion of revelation is given in Jesus Christ, the personal life which became transparent for the divine. This point of view was developed by Tillich in his three-volume *Systematic Theology* (1951–63). Other major works include *The Protestant Era* (1948), a series of essays on religious, cultural and political problems; *The Courage to Be* (1952), a religious existentialist interpretation of the meaning of faith; and three books of sermons, *The Shaking of the Foundations* (1948), *The New Being* (1955) and *The Eternal Now* (1963). He wrote an essay on Christian ethics entitled *Love, Power and Justice* (1954) and an apologia for his theological method entitled *Biblical Religion and the Search for Ultimate Reality* (1955).

Tillich's books and essays range widely over the whole spectrum of human culture and religious experience. He fused a deep Christian piety with the classic tradition of philosophical and Christian mysticism. This makes his method and results suspect to those who seek a sharper separation of faith from cultural forms; but it explains in part his deep attraction for those who seek a personal experimental understanding of their religious heritage. See also NEO-ORTHODOXY.

**BIBLIOGRAPHY.**—Full Tillich bibliographies will be found in *Religion and Culture: Essays in Honor of Paul Tillich*, ed. by Walter Leibrecht (1959), and *The Theology of Paul Tillich*, ed. by Charles W. Kegley and Robert W. Bretall (1952), a volume in *The Library of Living Theology*, which contains critical essays with a reply by Tillich and an autobiographical essay. Another autobiographical essay will be found in *The Interpretation of History* (1936), an English translation of some of Tillich's earlier German writings. See also Gustave Weigel, S. J., “Contemporaneous Protestantism and Paul Tillich,” *Theological Studies*, vol. xi (June 1950); Daniel D. Williams, *What Present-Day Theologians Are Thinking* (1959); G. Tavad, *Paul Tillich and the Christian Message* (1962). (D. D. WI.)

**TILLY, JOHANN TSERCLAES, GRAF VON** (1559–1632), the greatest general in the Bavarian service and so the principal commander of the Catholic League in Germany during the Thirty Years' War (q.v.). He was born in February 1559, at Tilly in Brabant. In 1568 his father, Martin Tserclaes, lord of Tilly, was exiled from the Spanish Netherlands as an adherent of Egmond (q.v.). Johann and his elder brother Jakob were brought up by the Jesuits in Liège and in Cologne, and in 1574 the family was reconciled to the Spanish regime in the Netherlands. Johann entered a Walloon regiment and served in the war against the Protestant Archbishop Gebhard (q.v.) of Cologne in 1583–84 and at the siege of Antwerp in 1585 under Alessandro Farnese (q.v.), whom he ever afterward acknowledged as his teacher. Having distinguished himself on the Catholic side in the French Wars of Religion, he went in 1594 to join the Holy Roman emperor Rudolf II's army campaigning against the Turks.

Tilly refused to side with the archdukes against Rudolf II, thereby incurring the enmity of the future emperor Matthias (q.v.). He therefore offered his service, in 1610, to Maximilian I (q.v.), duke and later elector of Bavaria, for whom he created the efficient Bavarian Army, backbone and spearhead of the Catholic League. Under the nominal leadership of Maximilian and hampered by the irresolute Graf von Bucquoy (C. B. de Longueval, commander of the emperor Ferdinand II's forces), Tilly in 1620 conducted the first campaign of the Thirty Years' War: he forced

HENRI DADMAN. LIFE © 1965. TIME, INC.  
TILlich. PHOTOGRAPHED IN 1965

the rebellious Estates of Upper and Lower Austria into unconditional surrender (July–August), outflanked the Bohemian troops and their Hungarian allies (September–October), and then marched straight on Prague, to win the decisive Battle of the White Mountain (Nov. 8).

In the following years Tilly conquered the Upper Palatinate and the Rhenish Palatinate for Bavaria and, not without occasional reverses, defeated and destroyed the armies of Ernst von Mansfeld (*q.v.*), Christian (*q.v.*) of Brunswick, and the margrave George Frederick of Baden-Durlach, making himself master of north-western Germany. For his victory over Christian at Höchst (June 20, 1622) he was made a count of the Empire.

In the war against Denmark (1625–29) Tilly with the army of the Catholic League gained the decisive victory of Lutter (Aug. 27, 1626), but the fruits of Denmark's defeat fell to the emperor Ferdinand II, who now employed an army of his own under Wallenstein (*q.v.*). Tilly was offered the duchy of Brunswick-Calenberg, but preferred a financial reward.

When the Swedish king Gustavus II Adolphus invaded Germany (1630), Wallenstein was in disgrace, and the command of the Imperial as well as the League forces was therefore entrusted to Tilly. His attempt to secure Magdeburg as a base from which to overawe Saxony and Brandenburg and to bar Gustavus Adolphus' advance into central Germany failed because the city, stormed on May 20, 1631, went up in flames. Swedish propaganda blamed Tilly for the destruction, which, however, was contrary to his intentions and interest. When Tilly, by order of the emperor and against Maximilian's wishes, invaded Saxony, the elector John George I was driven into the Swedish camp, and Tilly, egged on by G. H. von Pappenheim (*q.v.*) against his own better judgment, accepted battle and was completely defeated at Breitenfeld (Sept. 17, 1631). Tilly's last victory was gained over a Swedish detachment at Bamberg (Feb. 10, 1632). His attempt to prevent Gustavus Adolphus from crossing the Lech River into Bavaria at Rain failed, and he received a wound of which he died a fortnight later, at Ingolstadt on April 30, 1632. (S. H. S.)

**TILSIT:** see SOVETSK.

**TIMAEUS** (c. 350–c. 250 B.C.), Greek historian, whose writings shaped the tradition of western Mediterranean history, was born at Tauromenium (Taormina) in Sicily. He was expelled by Agathocles, the tyrant of Syracuse, and went to Athens where he studied rhetoric under Isocrates' pupil Philiscus and passed 50 years of his life. Whether he ever returned home is uncertain. The 38 books of his *Histories* went down to Agathocles' death in 289, but a separate work on Pyrrhus of Epirus seems to have reached the Roman crossing into Sicily in 264. Books 1–5 contained the early history of Italy and Sicily, books 6–33 the history of Sicily from the foundation of the Greek colonies to Agathocles' accession with digressions, sometimes touching on Greece, and books 34–38 a separate account of Agathocles. The *Olympionikai* ("Victors at Olympia") was probably a chronological study.

Timaeus was bitterly attacked by later historians, especially Polybius. Some of his faults, such as the composition of artificial rhetorical speeches, are common to the historiography of the age; but a somewhat naïve attitude toward marvels reflects a genuine feeling for folklore. He was spiteful to those he disliked such as Dionysius and Agathocles, and he exaggerated the virtues of the Corinthian general Timoleon. Above all he showed the faults of the armchair historian. But his interests were wide; he was assiduous in assembling material, including inscriptions; and Polybius' charge of ignorance and willful dishonesty is unjust. Timaeus' system of reckoning by Olympiads furnished a valuable chronological tool for his successors, including Polybius. He employed a pleasing "Asiatic" style, which Cicero approved.

**BIBLIOGRAPHY.**—Fragments in F. Jacoby, *Fragmente der griechischen Historiker*, vol. 3, no. 566 (1955; with commentary). See also Polybius, *Historiae*, book xii; J. B. Bury, *The Ancient Greek Historians* (1909); T. S. Brown, *Timaeus of Tauromenium* (1958). (F. W. WA.)

**TIMARU**, a city and port on the east coast of South Island, New Zealand, midway between Christchurch and Dunedin. Pop. (1961) 24,821. The first ship taking immigrants to New Zealand direct from Britain arrived there in January 1859. Timaru is now

the provincial centre of South Canterbury. The harbour, formed by breakwaters, can take ships of up to 18,000 tons. The chief exports are frozen meat, wool, flour, and cereal products, the processing of these being the city's main industries. A sunny, temperate climate, a splendid bathing beach, and easy access to Mt. Cook and the Southern Alps make Timaru a popular resort. (JA. A. G.)

**TIMBER:** see LUMBERING; WOOD.

**TIMBERLINE**, the boundary above which there is no tree growth. In any elevated area in low or middle latitudes the line is generally clearly marked, but its height is dependent not only on general but also on local climatic and soil conditions. See SNOW LINE.

**TIMBUKTU:** see TOMBOUCTOU.

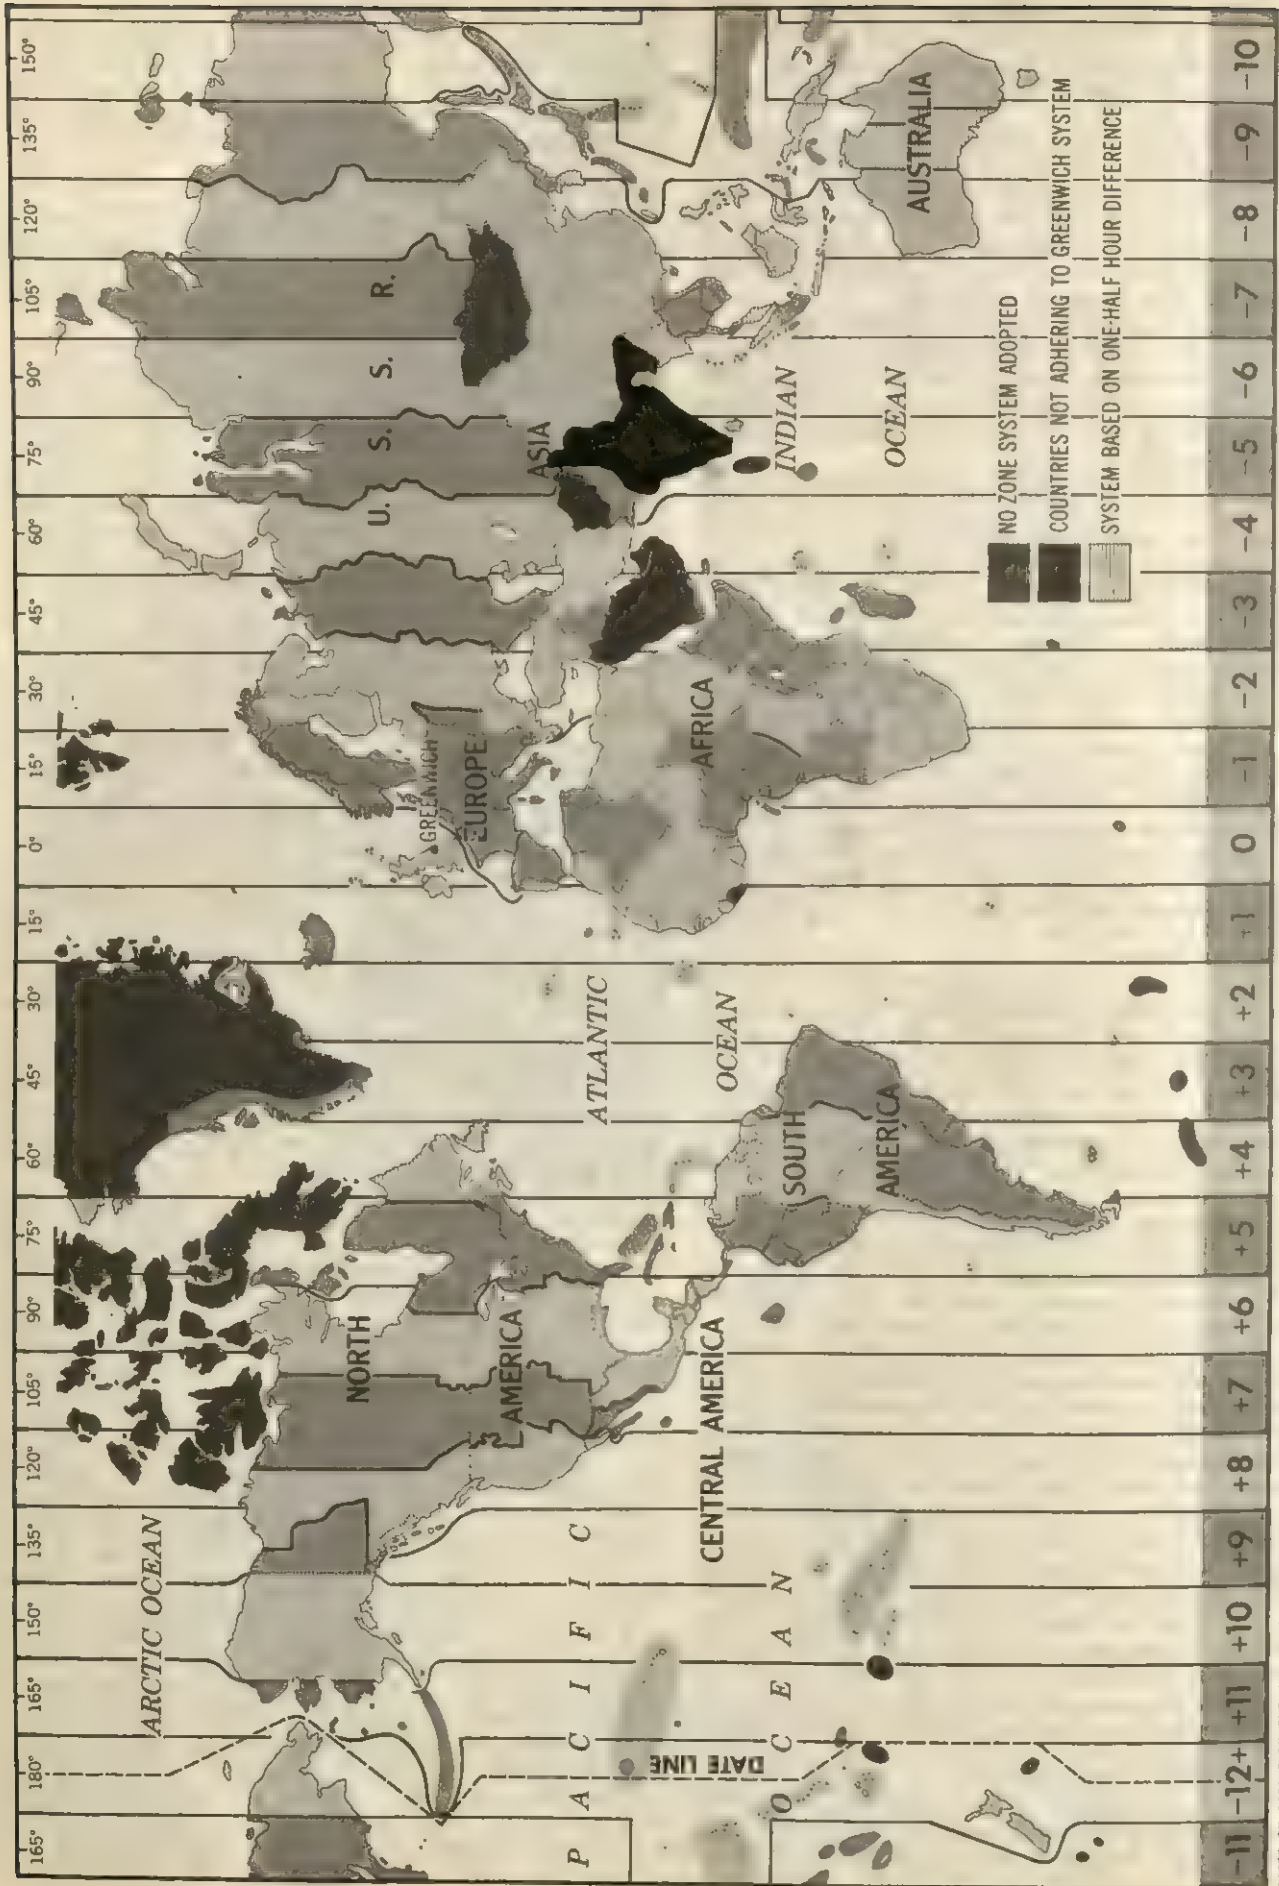

**TIME, STANDARD.** In an isolated community clocks and watches would be set to the local mean time (see TIME MEASUREMENT), and before the period of railway communication the different towns as a rule kept local time. The need for a more systematic plan of standard times was chiefly felt in the United States. While the railways in England were run by Greenwich time and the railways in France by Paris time, it was not to be expected that railway systems in the middle and western states would adopt Washington, D.C., time, differing by several hours from the local time of the region which they served. Hence each railway had its own time, or, in the case of the longer lines, several different time zones, and great confusion arose at overlapping points. The question of bringing order out of chaos through a system of standard time was actively discussed in the principal commercial nations during the decade before 1880, Sanford Fleming in Canada and Charles F. Dowd in the United States being the principal proponents of the system. This involved adopting for the whole earth 24 standard meridians 15° apart in longitude, starting from Greenwich. These meridians were to be the centres of 24 time zones; in each zone the time adopted would be uniform, and it would change by one hour in passing from one zone to the next. After long discussion railway managers of the U.S. and Canada decided to adopt the system. Zone time based on the Greenwich meridian is now adopted almost everywhere. In most countries the time differs by an integral number of hours from Greenwich time, in accordance with the original plan; but in some countries a compromise involving half-hour differences was adopted. European countries are ranged in three groups, keeping respectively Greenwich time, mid-European time (one hour fast), east European time (two hours fast). In the U.S. there are seven time zones, respectively 5, 6, 7, 8, 9, 10 and 11 hours slow on Greenwich time.

The advent on an international scale of shipping and, later, of air travel has necessitated world-wide agreement on the 15° time zone system. Slight adjustments have been made in some of these parallels of longitude so that a particular standardization may cover a specific geographical area; for example in certain countries in east Asia (see map). The parallel of longitude at 180° (12 hours) is also known as the "date line" because just to the west of this line countries are one calendar day ahead of Greenwich; again this line has been adjusted so that it does not pass through the middle of a country—in this case New Zealand. Some countries adopt, as an internal policy within their own borders, a zoning every 7½°, giving time intervals of one-half hour; examples are India, Pakistan and other countries in the far east.

In the summer months some countries advance their time by one hour, or adopt the time of the next zone to the east. Thus legal time in Britain is Greenwich time in winter and mid-European time in summer. The advantage of summer or daylight saving (*q.v.*) time depends much on the latitude, and it is scarcely suitable for more northerly or southerly countries; it is unpopular in agricultural communities, but is widely favoured in urban areas.

The advantage of adopting a continuous reckoning of the hours from 0 to 24 instead of using the divisions A.M. and P.M. is obvious, and this reckoning has been adopted for many public services in some countries, but confusion has arisen through uncertainty as to when 0 hr. occurs. Astronomers from time immemorial have used a 24 hr. reckoning beginning at noon, but for civil purposes

BASED ON DATA FROM THE U.S. NAVY HYDROGRAPHIC OFFICE

TIME IS CALCULATED FROM THE MERIDIAN OF GREENWICH, ENG. THE MIDDLE OF THE ZERO TIME ZONE PASSES THROUGH GREENWICH WITH ITS EAST AND WEST LIMITS 7° 30' ON EACH SIDE. EACH 15° ZONE EAST AND WEST OF THE INITIAL ZONE REPRESENTS ONE HOUR OF TIME. THE NUMBER OF HOURS THAT MUST BE ADDED TO OR SUBTRACTED FROM LOCAL TIME TO GIVE GREENWICH TIME IS INDICATED ON THE MAP FOR EACH ZONE

it has seemed more natural to count from midnight. At the meeting of the International Astronomical Union in 1922 astronomers were recommended to use time beginning at Greenwich midnight from 1925, but no recommendation was given as to the name. In England it was believed that the intention was to use the name Greenwich mean time (GMT) in a sense differing by 12 hr. from what it had previously meant. In other countries, however, other names were available for time counted from Greenwich mean midnight and these were used. At the meeting of the International Astronomical Union in 1928 it was decided to use *temps universel* (TU) in France, universal time (UT) in England and *Weltzeit* (WZ) in Germany. The designation Greenwich civil time (GCT), which had been used in England, France and the United States, was dropped, and it was recommended that anyone who still wanted to use time counted from noon should call it Greenwich mean astronomical time (GMAT). (A. S. E.; J. J. N.)

See *The American Ephemeris and Nautical Almanac* (annual) for detailed data; the *British Nautical Almanac* publishes annually a full list of standard times of the different countries and of those on non-standard time.

**TIME MEASUREMENT.** Time is a basic concept that deals with the occurrence of events. There is a definite order in which any two nonsimultaneous events occur at some location. If *A* and *B* are such events, either *A* occurs before *B* or *B* occurs before *A*. Between two nonsimultaneous occurrences there is a lapse of an interval of time.

The measurement of time involves establishing a precise system of reference for specifying when any event occurs, that is, specifying the epoch and establishing a standard interval of time. Astronomy and civil affairs are concerned both with epoch and with time intervals, whereas physics deals almost entirely with time intervals. The fundamental unit of time interval is the second.

A reference time scale could be based on any phenomenon that involves change with time, such as (1) the rotation of the earth or (2) the motion of a pendulum. To be generally useful it should be possible to determine the same numerical value of the time, within very close limits, anywhere on the earth. This condition is satisfied by the rotating earth but not by the pendulum.

Until recently, the rotation of the earth about its axis furnished the only time scale in general use, mean solar time. However, other independent time scales have recently come into use. Ephemeris time is based on the revolution of the earth about the sun, and atomic time is based on quantum changes in the state of atoms.

Mean solar time is slightly variable with respect to both ephemeris time and atomic time. The fundamental unit of time was formerly the second of mean solar time, but in 1956 it was replaced by the second of ephemeris time. In 1964 the second was officially redefined as the vibration rate of the cesium-133 atom.

Several kinds of time are required for different scientific and technical purposes. Celestial navigation and geodesy, for example, require mean solar time, and the study of planetary and satellite motions requires ephemeris time. It is necessary that the various kinds of time and their relations to each other be determined continually with the highest precision. The various kinds are discussed under the general headings, Rotational, Ephemeris, and Atomic.

### ROTATIONAL (NONUNIFORM) TIME

**Solar Time.**—The apparent daily motion of the sun from east to west provides a measure of time called apparent solar time, which is indicated by a sundial. The interval between two successive transits of the apparent sun across the meridian is called an apparent solar day.

The annual revolution of the earth about the sun causes the sun to appear to move eastward with respect to the stars. Hence, an apparent solar day is not equal to the period of rotation of the earth with respect to the stars. The apparent motion of the sun is  $360^\circ$  in a year, or nearly  $1^\circ$  per day, and an apparent solar day is almost 4 min. longer than the period of rotation.

The earth moves about the sun in an elliptical path in a plane called the ecliptic, which is inclined about  $23\frac{1}{2}^\circ$  to the Equator.

In consequence of these factors the component of the daily motion of the sun along the Equator varies. As a result, apparent solar days are of variable length, and apparent solar time is nonuniform.

The development of clocks and watches in the 17th century made apparent solar time unsuitable for civil use, and mean solar time was introduced. The mean solar day is the mean period of rotation of the earth with respect to the sun. Mean solar time is so defined as to be a measure of the rotation of the earth. The difference between apparent solar and mean solar time is called the equation of time. Its numerical value varies from 0 to about 16 min.

**Sidereal (Equinoctial) Time.**—For various astronomical purposes, such as locating a celestial object, the astronomer uses sidereal time. In the discussion given here astronomical coordinates, etc., are treated only briefly. For additional details see *ASTRONOMY: Observational Astronomy*.

The intersection of the true Equator and the ecliptic provides a fundamental reference point called the true vernal equinox or first point of Aries. Right ascensions are measured along the celestial Equator from the equinox. The interval between two successive meridian transits of the true equinox is called a true sidereal day. The hour angle of the true equinox, that is, the angle west of the meridian measured along the Equator, is true sidereal time, also called apparent sidereal time.

The true equinox is not fixed with respect to the system of stars but moves very slowly in a retrograde direction along the ecliptic, in a period of about 25,000 years. The secular, or steady, part of the motion is called precession and the periodic, or oscillating, part is called nutation. In consequence of nutation true sidereal days are of variable length. The maximum variation from the mean is only about 0.01 sec., but improvements in the pendulum clock made about 1925 required that uniform equinoctial time be introduced.

Mean sidereal time is defined as the hour angle of the mean equinox, that is, of the equinox freed of nutation. A mean sidereal day is the interval between successive transits of the mean equinox.

The difference between apparent and mean sidereal time is called the nutation in right ascension, or the equation of the equinoxes. It varies from 0 to a little more than 1 sec.

**Relation Between Solar and Sidereal Time.**—Mean solar time is defined as 12 hours plus the hour angle of the fictitious mean sun. The latter is a point moving uniformly in the celestial Equator with the mean speed of the apparent sun. In practice the right ascension of the fictitious mean sun is obtained from a formula, and the operational procedure is such as to keep mean solar time rigorously proportional to the speed of rotation of the earth.

During one mean solar day a clock keeping mean sidereal time gains 3 min. 56.555 sec. of mean sidereal time on a clock keeping mean solar time.

Apparent solar time and apparent sidereal time have two sources of nonuniformity: (1) inequalities arising from the motion of the earth about the sun and from the motion of the equinox; and (2) variations in the speed of rotation of the earth. The inequalities caused by (1) may be accurately calculated. To express the motion of the earth about the sun S. Newcomb constructed a detailed mathematical development called the theory of the sun, based on the laws of celestial mechanics. A theory of the motion of the earth about its centre of mass, including precession and nutation, was developed, similarly, by E. W. Woolard. Such developments allow the inequalities caused by (1) to be removed, giving mean solar and mean equinoctial time. The variations in speed of rotation of the earth include irregular changes of speed of unknown nature which cannot be determined, however, by computation.

**Time Units.**—A mean solar day is divided as follows:

- 1 mean solar day = 24 mean solar hours
- 1 mean solar hour = 60 mean solar minutes
- 1 mean solar minute = 60 mean solar seconds
- 1 mean solar day = 86,400 mean solar seconds

The other kinds of days are similarly divided, giving, for example, the mean sidereal second by subdivision of the mean sidereal day.

**Reckoning of Days and Hours.**—The day begins at midnight and runs through 24 hours. In the 24-hour system of reckoning, used in Europe and by military agencies of the United States, the hours and minutes are given as a four digit number. Thus 0028 means 28 minutes past midnight, and 1240 means 40 minutes past noon. Also, 2400 of May 15 is the same as 0000 of May 16. This system allows no uncertainty as to the epoch designated.

In the 12-hour system there are two sets of 12 hours; those from midnight to noon are designated A.M. (ante meridiem, before noon) and those from noon to midnight are designated P.M. (post meridiem, after noon). Neither A.M. nor P.M. may be used to designate either noon or midnight without ambiguity. To designate noon the word noon or 1200 should be used. To designate midnight without ambiguity the two dates between which it falls should be given unless the 24 hour notation is used. Thus, we may write midnight, May 15–16, or 0000 May 16.

Local mean time is the hour angle of the mean sun increased by 12 hours. Local mean time at Greenwich is called Greenwich Mean Time (GMT) or universal time (UT). The designation GMT is used in navigation. UT is the term used by astronomers. It would be inconvenient to use local time strictly, for no two places in different longitudes have the same mean solar time. The variation amounts to one hour for 15° of longitude, or about five seconds to the mile in middle latitudes. A system of zones was devised whereby within each zone the same mean time rules, but changes abruptly by one whole hour at its borders. Mean solar time, so regulated, is called zone time or standard time. (See TIME, STANDARD.) Standard time differs from UT by an integral number of hours.

Another convention regulates the date line: in traveling across it a calendar day is added to the reckoning in passing westward, or is dropped in passing eastward. (See DATE LINE.)

During World War I clocks were advanced by one hour in summer in various countries in order to save fuel by reducing the need for artificial light. The advanced time is known as summer time in Great Britain and as daylight-saving time in the United States. Advanced time is adopted each year by many European countries. In 1966 the U.S. Congress passed a bill that, as of 1967, established daylight-saving time throughout the nation; a state as a whole, however, could decide to remain on standard time.

During World War II all clocks in the U.S. were advanced, and remained, one hour ahead of standard time for the entire interval Feb. 9, 1942–Sept. 30, 1945; no changes were made during the summer. England used "double-summer time" for part of the year, whereby the clock was advanced two hours ahead of standard time.

**Practical Determination of Rotational Time.**—The determination of time is a highly specialized branch of astronomy which is usually carried out by a governmental observatory. The basic definitions concerning time determination are standardized by the International Astronomical Union (IAU), under whose auspices the Bureau International de l'Heure (International Time Bureau) at Paris makes comparisons of time determinations and provides certain data needed for the uniform reduction of observations.

The steps involved in the determination of universal time (UT) are as follows: (1) The transit of a star of known position is observed in order to determine local mean equinoctial (sidereal) time. (2) The longitude west of Greenwich is added to obtain the Greenwich sidereal time. (3) This is converted to UT by a mathematical formula in the form denoted UT0, discussed in further detail, below.

The apparatus required for time determination consists basically of a telescope and a clock. Notation is made of the reading on the clock at the instant of passage of a star of known position across a selected reference line on the celestial sphere which is fixed with respect to the observing station. This reference line is the local meridian for the first two instruments described below and is the small circle that is everywhere 30° from the zenith for the third instrument.

**Transit Instrument.**—This is a small instrument similar in mounting to a transit circle (*q.v.*). The telescope is constrained to move in the plane of the meridian. The reading of a clock being

checked is recorded on a chronograph at the instant of transit as noted by the observer.

**Photographic Zenith Tube.**—An instrument more accurate than the transit instrument for time determination is the photographic zenith tube (PZT), which was used for this purpose after 1934 at the U.S. Naval Observatory. The PZT is fixed in a vertical position, and only stars that transit near the zenith are observed. A basin of mercury reflects the rays of light from the stars as the rays pass through the lens and defines the zenith, which lies in the meridian.

The plate is held by a carriage which is driven by a motor so as to track the star being observed. Four exposures of 20 sec. each are made of each star, and the lens and plate are rotated 180° as a unit between exposures. The motion of the carriage during the exposures initiates timing impulses which are read on the clock being compared with the stars. By measuring the positions of the star images it is possible to determine what the clock read when the star crossed the meridian. A comparison with the predicted time gives the correction to the clock.

The PZT was designed by F. E. Ross for the determination of the variation of latitude. Ross followed the design of Sir George Airy's reflex zenith tube, installed at Greenwich, Eng., in 1851. Ross improved on this obsolete instrument by placing what is known as the second nodal point outside of the lens and by making the instrument photographic. The photographic plate, which is small, is placed just beneath the lens at the nodal point. The position of the image of a star on the plate thus becomes insensitive to the tilt of the lens.

This PZT, designated no. 1, was installed at Washington, D.C., in 1915 for the determination of the variation of latitude. It was adapted for the determination of time also in 1934 by F. B. Littell and J. E. Willis. A PZT of improved design was placed in operation in 1949 at a substation of the Naval Observatory at Richmond, Fla. A similar PZT was installed at Washington in 1954 to replace PZT no. 1. Several other observatories subsequently used the PZT.

**Impersonal Astrolabe.**—A. Danjon, of the Paris Observatory, devised an accurate instrument for time determination which is quite different from those described. (The use of the word astrolabe in this connection should not be confused with the designation for the astrolabe of the days before the telescope.)

The astrolabe makes use of a reflecting basin of mercury and a 60° prism to form direct and reflected images of a star. When the altitude of a star is exactly 60° the images coincide. In earlier forms of the instrument it was difficult to determine when coincidence occurred. Danjon introduced a Wollaston prism to obtain four images, two of which are suppressed. The observer manipulates a motor so as to keep the remaining images parallel to a spider thread, and the instant when the altitude is 60° is automatically recorded on a chronograph. Observations are made in various azimuths and both time and latitude are obtained.

**Practical Determination of Time Intervals.**—To indicate time and to measure time intervals various types of clocks have been developed.

**Pendulum Clocks.**—Galileo discovered about 1583 that the time of swing of a pendulum was nearly independent of the amplitude of swing. Christiaan Huygens contributed to the theory of the pendulum and had the first pendulum clock constructed in 1656. Numerous improvements were subsequently made, and pendulum clocks reached a high stage of precision from 1900 to 1925. The rates of the best pendulum clocks are constant to about 0.001 sec. per day. Pendulum clocks, however, are no longer used in precise timekeeping, having been replaced by the quartz-crystal and atomic clocks.

**Quartz-Crystal Clocks.**—A quartz crystal, if deformed, produces a difference in electric potential across certain of its faces. Conversely, a difference in electric potential produced across certain faces of a quartz crystal causes it to become deformed. This property, known as the piezoelectric effect, enables the quartz crystal to be incorporated in an electronic oscillator. The frequency of oscillation is controlled by the frequency of mechanical vibration of the crystal. (In physics, frequency is the number of occur-

rences per unit of time of a repetitive phenomenon. Frequency  $f$  and period  $p$  of a cyclic occurrence are related by the expression  $f = 1/p$ . The frequency of vibration is dependent on temperature so that the crystal of the oscillator of a clock is kept at a constant temperature in a small oven.

The oscillator frequency may be several million cycles per second (cps). This is divided down by a device known as a frequency divider to 1,000 cps. This frequency then is amplified and drives a synchronous electric motor, which in turn drives the hands of a clock to indicate hours, minutes, and seconds. Also, sharp seconds pulses are produced in some clocks with an accuracy of a fraction of a microsecond.

Quartz crystals change frequency with age; generally they tend to run faster. This aging, however, can be made very small by careful design and manufacture. A particularly high-grade crystal is the 2.5 Mc-sec. crystal developed by A. W. Warner of the Bell Telephone Laboratories. Oscillators with such crystals have drift rates as small as 1 part in  $10^{12}$  per day; that is, the rates are stable to about 0.1 microsecond per day.

The use of quartz as a frequency control was described by W. G. Cady in 1922. In 1928 W. A. Morrison and J. W. Horton built the first quartz-crystal clock at the Bell Telephone Laboratories. P. Sollenberger introduced a crystal-controlled clock for the automatic transmission of time signals at the U.S. Naval Observatory in 1934. About 1942 timekeeping at the Greenwich Observatory and at the Naval Observatory was based on a combination of pendulum clocks and quartz clocks. A few years later the quartz clocks came into sole use at these observatories.

**Atomic Clocks.**—These clocks, described below, furnish the unit of time with the highest precision. (See also CLOCK.)

**Variations in Speed of Rotation of the Earth.**—Rotational time is variable with respect to ephemeris time and atomic time because of variations in the speed of rotation. These variations are of three types: secular, irregular, and periodic.

Tidal friction causes a progressive increase in the length of the day of about 0.001 sec. per century, an example of secular variation. This effect was found from studies of ancient lunar eclipses.

About 1900 Simon Newcomb found that during the preceding two centuries the moon was sometimes ahead of its computed position and sometimes behind. He suspected that this might be due to an error in the clock (the earth) instead of the lunar tables, but was not able to decide the matter. Later studies by E. W. Brown in 1926 and W. de Sitter in 1927, utilizing both the moon and planets, indicated that the rotation of the earth was not uniform. Sir Harold Spencer Jones definitely proved that the rotation was nonuniform. He showed that discrepancies in the orbital motions of the earth, Venus, and Mercury corresponded to those shown by the moon; the apparent errors in position at any time were proportional to the mean motions.

It was formerly supposed that irregular changes in speed of rotation occurred suddenly. However, D. Brouwer suggested in 1952 that such changes occurred gradually. Observations of universal time compared with atomic time indicate that sudden changes in acceleration but not in speed of rotation occur. This tends to confirm Brouwer's hypothesis.

Variations with periods of one year and six months were first obtained with some degree of accordance with recent data by N. Stoyko in 1937 at the Bureau de l'Heure. The coefficient of the annual term found by Stoyko was about 0.060 sec. It is now agreed that the coefficient is about 0.025 sec.

Y. Mintz and W. Munk have calculated the effects of winds on the speed of rotation of the earth. There is a reasonable accordance of their results with astronomical observations for the annual term.

The moon affects the time determined in two ways, directly by altering the direction of the vertical and indirectly by tidal action on the earth's crust. A change in the form of the earth alters its moment of inertia and hence its speed of rotation. The period of the direct term is 0.5 day. There are two tidal terms of short periods, 13.6 days and 27.6 days. The amplitudes of all three terms are each about 0.001 sec. in time, and all three were detected with the PZTs of the Naval Observatory.

**Corrected Universal Time (UT2).**—During the course of a year or so universal time is nonuniform because of the following effects: (1) polar motion; (2) annual and semiannual terms in speed of rotation of the earth; and (3) direct and indirect lunar terms. The International Astronomical Union decided that as of Jan. 1, 1956, universal time would be computed so as to include corrections for (1) and (2); (3) is too small to be of effect. The time so computed is denoted UT2; it is relatively uniform time.

The notation adopted is as follows:

UT0 is classical universal time.

UT1 is UT0 corrected for (1).

UT2 is UT0 corrected for (1) and (2).

UTC is coordinated universal time.

UTC is the time given by radio time signals; it differs from UT2 by less than 0.1 sec. UT0 and UT1 are used in precise surveying. Corrections are furnished to make it possible to convert from one system to another.

Although the seasonal terms are not strictly repetitive and are largely empirical, it was decided that a correction for these terms could be employed advantageously.

The polar-motion term arises from the motion of the pole of rotation in an approximate circle of about 30 ft. in radius (see *GEODESY: Variation of Latitude*). The motion of the pole causes not only the latitude of an observatory but also its longitude to vary in a period of 14 months. The instantaneous value of the longitude must be added to the observed local mean time to obtain UT if UT is to be the same for all observatories. Formerly the polar motion was obtained much in arrears, but a Rapid Latitude Service was established by the International Astronomical Union in 1955 for the needs of time determination.

The Bureau de l'Heure computes and distributes the corrections for variation of longitude, which differ for each observatory, and the correction for seasonal variation, which is alike for all observatories.

## EPHEMERIS TIME

**Definition.**—The motions of the celestial bodies occur in accordance with the laws of celestial mechanics, first propounded by Sir Isaac Newton. They were modified slightly by the theory of relativity of Albert Einstein.

Knowing the masses, coordinates, and velocities of a number of bodies at one epoch, it becomes possible to find the coordinates for any epoch,  $t$ , by the solution of the appropriate differential equations.

The solution for some particular coordinate of one of the bodies, say  $x_1$ , may be written

$$x_1 = f_1(t; a_1, a_2, \dots, a_n) \quad (1)$$

where  $f_1$  is a function of  $t$  and the constants of integration  $a_1, a_2, \dots, a_n$ . By postulate, the  $t$  of equation (1) is uniform astronomical time. Assigning numerical values to the constants for a particular planet or satellite defines its orbit. An ephemeris may be constructed which gives the coordinates, usually for uniformly increasing values of  $t$ . The ephemeris may be used to find the coordinates of the body if  $t$  is given, or to determine  $t$  if the coordinates are observed. The time  $t$  which enters in the equations of motion, the solution, and the ephemeris has been given the name ephemeris time.

The orbital motion of the earth about the sun has been selected as the standard to define the numerical measure of ephemeris time. The position of the earth in its orbit is obtained by observing the position of the sun with respect to the stars. *The Tables of the Sun* of Simon Newcomb have been adopted by astronomers for computing the coordinates of the earth as a function of ephemeris time.

In practice, ephemeris time is obtained from the orbital motion of the moon by observing its position with respect to the stars. The moon's orbital motion is much faster than the earth's, and the moon is easier to observe than the sun. Coordinates of the moon as a function of ephemeris time are given in the *Improved Lunar Ephemeris*, published in the national ephemerides, which is based on the lunar theory of E. W. Brown.

The lunar-solar tides on the earth produce a couple which affects the orbital motion of the moon. The lunar ephemeris contains a term, the coefficient of which is based on past observations, to correct for this effect. If the tidal couple should change in the future, the lunar ephemeris would not be in strict agreement with the solar ephemeris. For this reason the moon is not used as the standard to define ephemeris time.

**Determination of Ephemeris Time.**—Large transit instruments, also called meridian circles, are used to determine the position of the sun and moon with respect to the stars. The position of the moon may be determined visually from meridian transits or from the occultation of a star of known position.

A dual-rate moon position camera developed at the U.S. Naval Observatory in 1952 by W. Markowitz enables the position to be obtained photographically. By means of a dark glass filter, which tilts, the moon is held fixed relative to the stars in the background during a simultaneous exposure of 20 sec.

An observation of the moon gives its apparent coordinates for an epoch recorded in universal time. The observed geocentric coordinates are obtained by correcting for parallax. The computed geocentric coordinates of the moon are tabulated as a function of ephemeris time in the *Improved Lunar Ephemeris*. The Ephemeris is entered with the observed coordinates and the corresponding ephemeris time is taken out. The difference between ET and UT is given by the formula  $\Delta t = ET - UT$ .

**The Second.**—Until 1955 the fundamental unit of time was the second of mean solar time, defined as  $1/86,400$  of the mean solar day. Because of variations in the speed of rotation of the earth the second of mean solar time is not a constant unit of time. A redefinition of the second as  $1/31,556,925.9747$  of the tropical year for 1900 January 0 at 12 hrs. ET was adopted by the International Astronomical Union in 1955, at Dublin, and by the International Committee on Weights and Measures in 1956, at Paris. The latter group in 1964 officially adopted the transition between two specific energy levels of cesium-133 as the definition of the second.

### ATOMIC TIME

**Definition.**—According to the quantum theory an atom (or molecule) can exist in various quantum states, each of which has an associated energy level,  $E$ . When a transition from a higher to a lower level occurs, electromagnetic energy is radiated whose frequency (oscillations per unit of time) is

$$\nu = \frac{(E_1 - E_2)}{h} \quad (2)$$

where  $E_1$  is the initial energy,  $E_2$  is the final energy, and  $h$  is Planck's constant.

Each transition produces a spectral line. For visible radiation, (light waves) the frequency is about  $5 \times 10^{14}$  cps. This is too high to permit counting of individual cycles. The development of methods of generating frequencies of the order of  $10^{10}$  cps opened up the possibility of utilizing spectral lines in the one-centimetre microwave region for frequency control.

**Ammonia.**—R. V. Pound outlined in 1946 the use of spectral lines to stabilize an oscillator, and in 1947 W. V. Smith and co-workers confirmed the method of Pound by constructing an oscillator that was stabilized in frequency with the 3,3 inversion line of ammonia ( $\text{NH}_3$ ). W. D. Hersberger and L. E. Norton stabilized a klystron oscillator with ammonia in 1948. H. Lyons and co-workers used an ammonia-controlled oscillator in 1949 to control a clock for brief periods at the National Bureau of Standards, Washington, D.C.

In the preceding applications ammonia is used in absorption. Radio frequency (rf) energy is introduced into a cell containing ammonia and some of the energy is absorbed if the rf field matches the frequency at which the ammonia inversion occurs. The absorption of energy can be observed with a suitable detector.

A spectral line has a finite width so that transitions occur over a range of frequencies. Various techniques are employed to narrow the range, but in the case of ammonia in absorption basic difficulties appeared to limit the degree to which this can be done.

C. H. Townes developed in 1954 a microwave amplifier called

a maser (*q.v.*), which is stabilized in frequency by ammonia in emission, which has much higher precision. The ammonia molecule exists in two states, with a slight energy difference. These are separated electrostatically and those in the higher state enter a cavity. Some of the molecules fall to the lower state, with the emission of radiation.

The frequency of ammonia devices depends somewhat upon their construction and also on the isotope of N in the  $\text{NH}_3$  molecule. Approximate frequencies are 23,870,129,300 cps for  $\text{N}^{14}$  and 22,789,421,700 cps for  $\text{N}^{15}$ .

**Cesium.**—The cesium atom includes two energy states that differ slightly, depending on whether the spin of the outer electron is the same or opposite to the nucleus. A beam of cesium atoms issues from an oven and travels along a tube past a magnet. Those of one state are deflected to hit the wall of the tube. The others pass through an rf field and then approach a second magnet. If the frequency of the rf field, which can be varied, is correct, transitions occur and the atoms will be deflected by the second magnet to hit a detector. No atoms can hit the detector if the rf frequency is not equal to the cesium transition frequency. The beam technique for the study of atoms and molecules was developed by I. I. Rabi and co-workers about 1939.

A method developed by N. F. Ramsey of exciting the atoms with the rf field provides a spectral line with a sharp central peak. Early experiments with a cesium beam were made by H. Lyons and co-workers in 1952.

In June 1955 L. Essen and J. V. L. Parry, at the National Physical Laboratory, Teddington, Eng., first placed in operation a cesium beam atomic standard of high precision which made possible the formation of an atomic time scale. In a joint experiment carried out with the U.S. Naval Observatory the frequency of cesium was found to be  $9,192,631,770 \pm 20$  cps (of ephemeris time). The value 9,192,631,770 cps was adopted provisionally to reproduce the second of ephemeris time; in 1964 the second was officially redefined in terms of this frequency.

Cesium beam oscillators have been developed by the National Bureau of Standards, Boulder, Colo.; Swiss Laboratory of Horological Research, Neuchâtel, Switz.; National Research Council, Ottawa, Can.; and elsewhere. Small commercial models weighing about 65 lb. and having an accuracy of about 5 parts in  $10^{12}$  are made in the U.S. Such atomic clocks are transported in airplanes for synchronizing clocks to 1 microsecond.

A system of atomic time, denoted A.1, based on the above frequency, was established by the U.S. Naval Observatory in 1958. The epoch of atomic time was made 0h 0m 0s when UT2 was 0h 0m 0s on Jan. 1, 1958.

**Hydrogen.**—A hydrogen maser was developed by N. F. Ramsey and co-workers at Harvard University. Commercial models have an accuracy of about 1 part in  $10^{12}$ . The frequency, relative to cesium, is 1,420,405,751.8 cps.

**Thallium.**—J. Bonanomi of the Neuchâtel Observatory has utilized a thallium beam, obtaining high precision. The frequency is 21,310,833,945 cps.

**Rubidium.**—Gas cells employing rubidium have been developed in the U.S. Some of these are constant in frequency to 1 part in  $10^{11}$ . The gas cells are not standards in the sense of beam tubes. The frequency of the rubidium gas cell, about 6,834,682,610 cps, depends on the construction and adjustments, whereas beam tubes are nearly independent of such factors.

**Radioactivity.**—Atoms of a radioactive element decay at a rate which depends upon the element but which appears to be independent of temperature, pressure, etc. A clock could be constructed based on radioactive decay but would not measure time interval with high precision. The process is very useful, however, as a means of measuring long intervals of time. (See *GEOCHRONOLOGY*.) It has been ascertained, thus, that certain rocks were formed billions of years ago. Early studies utilized the decay of uranium and thorium into lead. Other transformations, such as radioactive rubidium to strontium and radioactive potassium to argon, are now also used for the dating of rocks.

Carbon-14 dating, developed by W. F. Libby, enables objects having carbon to be dated over the range 100 to 50,000 years.

Carbon-14, produced in the atmosphere by cosmic rays, enters living matter in a fairly definite ratio to carbon-12 which does not decay. A determination of the ratio of  $C^{14}$  to  $C^{12}$  in an object gives its age. The half life of  $C^{14}$  is about 5,600 years.

**Ephemeris Time and Atomic Time.**—Celestial bodies are affected by the force of gravitation, and atomic particles, by electrical and nuclear forces. According to some cosmological theories the relation of these forces to each other may change with time. If this is true, then ephemeris time and atomic time would not be equivalent time scales, and the frequency of cesium in cycles per second of ephemeris time, for example, would change. The change, if it exists, would be very small, perhaps 1 part in  $10^{10}$  or  $10^{11}$  per year. It will require many years, perhaps 20, to determine if such a divergence exists.

### USES OF TIME SYSTEMS

Universal time is required for celestial navigation, precise surveying, satellite tracking, and whenever the rotational position of the earth about its axis must be known. Ephemeris time is required for studying the motions of celestial bodies, but need not be available immediately; it may be used in arrears. Atomic time makes the second of ephemeris time, the fundamental unit of time interval, available immediately.

**Transmission of Time and Frequency.**—Accurate time is needed for the tracking of artificial satellites, precise surveying, navigation, and for other technical and scientific purposes. These needs are met by the transmission of time signals by radio stations such as NBA, Panama Canal Zone; WWV, Beltsville, Md.; and GBR and MSF, Rugby, Eng.

Transmissions of time signals of many countries are coordinated to 0.001 sec. Constant frequency is transmitted each year; it is offset from the atomic frequency so as to provide time pulses close to those of universal time. The frequency is maintained constant with respect to atomic standards to 1 part in  $10^{10}$ . Thus, the same transmission provides both universal time, needed for navigation, and constant frequency, needed in physics.

The navigational system of loran-C provides high accuracy for a range up to about 1,000 mi. The East Coast U.S. chain, controlled by the U.S. Naval Observatory, provides time signals with a precision of one microsecond.

Artificial satellites are used for time synchronization. In August 1962 the communication satellite Telstar, of the Bell Telephone Laboratories, was used for clock synchronization between the U.K. and the U.S. An accuracy of 1 microsecond was obtained. In February 1965 the U.S. satellite Relay 2 was used to synchronize clocks in the U.S. and Japan to 0.1 microsecond. The U.S. Navy navigational satellites, developed by the Applied Physics Laboratory, carry clocks. These provide synchronization to about 30 microseconds.

### RELATIVITY AND TIME MEASUREMENT

A definition of synchronization for clocks located at different points may be readily established if the clocks are stationary with respect to each other. If moving in different frames of reference, however, difficulties arise.

Clocks can be synchronized by means of electromagnetic signals, either light waves or radio waves. The Michelson-Morley experiment had shown that the velocity of light as measured by any observer was the same, irrespective of his motion in space. The theory of relativity provides a means of relating the times indicated by clocks moving with respect to each other which is consistent with the result of the experiment.

In Newtonian mechanics time is absolute; simultaneity may be defined for the entire universe. This is not true, however, for relativistic mechanics. Clocks which are synchronous in one frame of reference may not be synchronous in another.

Some of the consequences of the theory of relativity appear paradoxical and have caused much controversy. Relativistic effects depend upon the ratio  $(v/c)^2$ , where  $v$  is the velocity of the moving object and  $c$  is the velocity of light. The velocities involved on earth that concern synchronization of clocks are so small that the relativity effects are negligible.

A clock in an artificial satellite, compared to a similar clock at rest at the surface of the earth, would run slower with increasing speed but faster with increasing height (opposite of the gravitational red shift).

See also references under "Time Measurement" in the Index.

**BIBLIOGRAPHY.**—Systems of astronomical time are treated completely in ch. 3 of *Explanatory Supplement to the Astronomical Ephemeris and the American Ephemeris and Nautical Almanac* (1961), prepared jointly by the Nautical Almanac Offices of the U.K. and U.S. Summary on timekeeping, quartz clocks, and atomic standards: F. D. Lewis, *Proc. Inst. Radio Engrs.* (Sept. 1955). W. H. Munk and G. J. F. MacDonald, *The Rotation of the Earth* (1960). Dynamical theory of rotation of the earth, precession, and nutation: E. W. Woolard, *Astr. Pap., Wash.*, vol. 15, pt. i (1953). Cesium resonator: L. Essen and J. V. L. Parry, *Phil. Trans.*, vol. 250, p. 45 (1957). (W. Mz.)

**TIMGAD**, the modern name of the Roman city of THAMUGADI, situated on the high plateau north of the Aurès Mountains in northeastern Algeria. The modern town, in Batna department, had a population in 1960 of 1,984.

The city was founded by Trajan in A.D. 100 as a colony of veteran soldiers, its full name being Colonia Marciana Traiana Thamugadi. The site was of strategic importance in the defense of Numidia (*q.v.*), as it was on the military road running from Theveste (Tebessa) to Lambaesis (Lambessa), the station of the third legion (*legio III Augusta*). From Thamugadi roads ran north through Cirta (Constantine) to the Mediterranean at Rusicade (Skikda, formerly Philippeville) and northwest to Sitifis (Setif). The country immediately north of the Aurès range was fertile, and Timgad enjoyed a long period of prosperity. Toward the end of the 4th century it was the seat of the bishop Optatus, one of the most violent supporters of the Donatist schism (see DONATISTS). The city was sacked by Berber tribes toward the end of the Vandal supremacy in Africa; after the Byzantine reconquest a fortress was built near the ruins about 535, which probably survived till the Arab conquest in the 7th century.

Timgad, which held 10,000–15,000 inhabitants, is notable as the site of the most extensive and best-preserved Roman remains in North Africa, almost the entire city having been excavated by French archaeologists in the 19th century; buildings mentioned below are the more important of those of which substantial remains survive. The original plan of the city was of the classic Roman type, quasi-military in appearance with all streets intersecting at right angles. At first its shape was almost a square, but very soon building spread outside this area. The main east-west street (*decumanus maximus*) was aligned on the Theveste-Lambaesis road; entry from the west was through a triumphal arch often wrongly attributed to Trajan. Many of the public buildings were on a slight eminence in the centre of the city; the forum, 160 by 140 ft. (50 by 43 m.), situated at the junction of the main north-south street (*cardo maximus*) with the *decumanus maximus*, was flanked on the north by shops, on the east by a basilica, while part of its western side was occupied by the *curia* (council chamber). Near the forum was a set of public conveniences with one of the most efficient disposal arrangements known from Roman times. The ruins of the *capitolium* (temple of Jupiter, Juno, and Minerva) lie to the southwest just outside the original city boundary; other temples existed, such as that dedicated to the 'Genius of the city. South of the forum lay the theatre, which could hold about 4,000 persons. Timgad was exceptionally well provided with that essential feature of Roman city life, public baths; there were at least 12 of various sizes and dates, the largest being to the north of the city. There were several markets and a public library, and a number of Christian churches and chapels, including the Donatist "cathedral," perhaps built by Optatus. The remains of the Byzantine fortress are substantial.

See C. Courtois, *Timgad: antique Thamugadi* (1951). (B. H. WA.)

**TIMISKAMING:** see PRECAMBRIAN TIME.

**TIMIȘOARA**, a city of western Rumania, lying on the Bega river and canal, chief town of the Banat (formerly Timișoara) administrative and economic region. Pop. (1963 est.) 150,257. It consists of the inner town, once strongly fortified, and outlying suburbs, the intervening space, the former glacis, having been laid out in park areas. Principal buildings include the Roman Catholic cathedral, built (1736–73) under Maria Theresa; the Greek Or-

thodox cathedral; and a castle built by János Hunyadi in 1442. Timișoara is a centre of commerce and has developed industrially, especially since World War II. Its manufactures include electrical apparatus, chemical and building materials, leather-work and footwear, and, especially, textiles. It is also an important cultural centre, with a university and three institutions of higher education; two state theatres (one German-language); a state opera and ballet; a regional and town library; and a symphony orchestra.

First mentioned in a document dating as far back as 1242, Timișoara became a town at the beginning of the 14th century and was fortified by Charles I (king of Hungary 1309–42), who lived there several years. The Hunyadi family residence was also there. In 1514 the peasant leader György Dózsa was defeated by the Transylvanian vaivode John Zápolya near Timișoara, captured, and killed. The town was held by the Turks from 1552 to 1716. After the peace of Passarowitz (1718) the town, with the whole Banat, was annexed by the Habsburg Empire. It was besieged by the Hungarian revolutionists in 1849, the town successfully resisting for 107 days, and occupied by Serbia in 1919; by the Treaty of Trianon (1920) it was allotted to Rumania.

BANAT REGIUNE, bordering on Yugoslavia, is part of the larger territory of Banat, the other parts of which are in Hungary and Yugoslavia (see BANAT). Area 8,417 sq.mi. (21,800 sq.km.). Pop. (1963 est.) 1,241,832. It is divided into 12 administrative districts, and the chief towns, outside Timișoara, are Arad (pop. [1963 est.] 114,494), Reșița (47,389), Lugoj (32,142), and Caransebeș ([1964 est.] 18,158). Mineral products of the region include coal, iron, manganese, lead, copper, chromite, and marble. Its manufactures (outside Timișoara) comprise iron and steel, machine tools, timber processing, wood distillation, etc. Chief agricultural products are grains (wheat, maize, barley, oats, rice), commercial crops (sugar beets, hemp, rape, tobacco, flax), potatoes, and fruit. Livestock breeding is important.

**TIMMERMANS, FELIX** (1886–1947), Flemish writer, an outstanding representative of regional literature, was born at Lier, July 5, 1886. He made his name with the novel *Pallieter* (1916; Eng. trans. 1924), an "ode to life" written after a moral and physical crisis. To express his praise of life, Timmermans depicted his native Brabant as a paradise and created a character, Pallieter, who has taken his place in literature as the embodiment of a typically Flemish enjoyment of living: at once sensual and mystical, because for him the world's joys are the gift of God. Timmermans was also a painter and illustrator, and found inspiration in old prints and the paintings of Brueghel. For his characters he drew on the people of his native town. His kindly, humorous style, succulent language, wealth of anecdote, sympathetically carica-

tured characters, and pictorial skill hide his lack of depth. As well as many novels and short stories, he wrote romanticized biographies of Brueghel (1928), St. Francis (1932), and Adriaen Brouwer (1948), travel tales, autobiographical works, and plays.

In 1935 he reached new heights with *Boerenpsalm*, a song of praise showing keen insight into life and a new lyrical strength. The lighthearted sensuality of *Pallieter* is modified by a deeper knowledge of suffering, and praise of nature gives way to praise of humanity represented by the peasant, Wortel, who feels that his life is in God's hands.

Warm colouring is the outstanding characteristic of Timmermans' manner. His expressive style is rooted in the language of the people and excels in the spontaneity and variety of its imagery. It is suited both to the treatment of sensual and spiritual subtleties and to the revelation of Timmermans' exuberant yet melancholy temperament.

Another aspect of his art is shown in some prose works of great restraint (*De zeer schone uren van juffrouw Symforosa, begintjien* [1918]; *Ik zag Cecilia komen*, [1938]) and in the few serene poems (*Adagio*, 1947) written shortly before his death at Lier, Jan. 24, 1947.

Lebenstage und Wesenszüge eines Dichters* (1949); Lia Timmermans, *Mijn vader* (1951); K. Goossens, *F. Timmermans en de mystieke blijdschap* (1951); J. de Ceulaer, *De mens in het werk van F. Timmermans* (1957); F. Timmermans (1959); A. Westerlinck, *De innerlijke Timmermans* (1957). (R. F. Ls.)

**TIMMINS**, the principal town in the Porcupine gold mining area of northern Ontario, Can., is 268 mi. (431 km.) N of North Bay on the Mattagami River and the Ontario Northland Railway. It was founded in 1911 by Noah Timmins to house employees of the Hollinger Mine, but is not a company town. The town is laid out in grid fashion on sandy terraces overlooking the Mattagami River and prides itself on being the largest town in Canada—the population, (1961)29,270, is larger than that of many Canadian cities.

The Hollinger Consolidated Gold Mines, Ltd. became the largest producer of gold in Canada. Mine shafts extend to depths of over 5,000 ft. (1,500 m.) and there are many miles of underground workings. In the 1950s and 1960s about 1,000,000 tons of ore were mined each year, and the annual gold production amounted to more than 250,000 oz. Hydroelectric plants at Wawaitin Falls and Sandy Falls furnish energy for the town and for the mines. Power is also brought from the Abitibi River. A major copper-zinc-silver find north of Timmins was reported in 1964.
